COUES'S "BIRDS OF THE COLORADO"

Birds of the Colorado Valley. By Elliott Coues. Part I. *Passeres to Laniidæ.* Bibliographical Appendix. United States Geological Survey of the Territories. Miscellaneous Publications—No. 11. 8vo, pp. 807. (Washington, 1878.)

WHAT is commonly called a "popular" zoological work is nearly always one that is bad. The knowledge possessed by the writers of such books is seldom greater than that of the public for whose benefit the books are ostensibly published, and is far behind that of a moderately well-informed student of the particular branch concerned. We shall name no names, but our readers will doubtless be able to supply several instances n support of this assertion without inconveniently taxing heir memories. Within a very short space of time they iave seen the works of two English naturalists, whose vritings have long attained a classical position, subjected o such treatment at the hands of "popular" editors as vould "make the angels weep," if those celestial beings ›e actuated by human affections, while the number of ›ooks independently put forth by "popular" sciolists is ›ast counting. These books have their day—and someimes it unfortunately is a long day. Granting that they o some good by administering to or fostering the taste or natural history already so widely spread, the evil they erpetrate is far greater. This evil lies first in their nstilling for the most part erroneous ideas into the nnocent pupil, and secondly in their occupying and ncumbering the ground to the exclusion of better books, hich drop still-born from the press. The struggle for xistence is admittedly slow in operation, and though we oubt not which way the triumph will eventually be, the nd is far off, and ere it arrive dire mischief is done. he falsest notions are promulgated, the feeblest arguents are maintained, and the learner at last discovers his sorrow that, instead of proceeding joyously on his ›urse, he has to unlearn what he has acquired. Someing may be said in favour of the mental discipline thus undergone, but on the other hand must be weighed the waste of time that attends the process, and the spirit of the age is against any discipline that is in the least doubtful of effect. As an epithet to a work on zoology, "popular" in nine cases out of ten really means debasing.

It is therefore with great pleasure that we can declare the volume before us—"The Birds of the Colorado Valley"—to be a popular book, not in the common sense but in the uncommon, highest and best meaning of the phrase. Dr. Coues has long since attained a scientific reputation that cannot be gainsaid. His numerous works are as well known and as highly esteemed on our side of the Atlantic as on his own, and one quality which is conspicuous in all of them is their thoroughness. When Dr. Coues writes a sentence he is in earnest, and there is no mistaking what he says. Whether the subject be the laboured description of an animal whose fur or plumage is mottled and diversified by the most delicate combination of tints—many a rodent, an owl, or goatsucker for example; the unravelling of an abstruse question of complicated synonymy; an account of the economy of a beast or bird to be given from his own wide experience or compiled from the observation of others—this quality is manifest. He has of course his faults. Some of them he has not been slow to acknowledge, but there is seldom a fault in his works that can be fairly called a blunder, and even such blunders were they twice as great and twice as numerous we could readily pardon, for there runs through all his writings, showing itself at times even in the driest spots, a humorous vein that can scarcely fail to excite a sympathetic flow even from the sternest of scientific breasts. In this volume Dr. Coues gives freer play to his lighter mood than, we think, in any of his former works, and at times (though he can be as serious when he pleases as the strictest man of science would wish) there is a boyish elasticity in his style which is exceedingly pleasant. He is always a readable author, whereby we mean that apart from the value of the information we derive from his statements, he clothes them in agreeable language, which far too many of his zoological brethren neglect to do. Nor is there any attempt at fine writing, which of course is a great mistake—*the* mistake in fact

into which "popular" naturalists fall. Here is a passage which we extract, since it relates to a species now considered to be common to Europe and North America—the Tree-Creeper (*Certhia familiaris*)—and its accuracy will be recognised by all who have watched the bird in this country:—

"The leading trait of the Brown Creeper is its extraordinary industry—the 'incomparable assiduity,' as it has been well styled, with which it works for a living. Like all good workers, the creeper makes no fuss about it, but just sticks to it. So quietly, yet with such celerity, does it go about its business that it scarcely seems to be at work, but rather to be rambling in an aimless way about the trunks of trees, or at most only caring to see how fast it can scramble up to the top. During all this time, however, the bird is on the alert in the search for insects, which it extracts from their lurking-places with such dexterity that its progress is scarcely arrested for a moment; and the number of these minute creatures yearly destroyed is simply incalculable. The creeper is strongly attached to the trunks of large trees, being seldom seen foraging on even the larger branches; and it has a great fancy for travelling upward. These two traits combined result in its marked habit of beginning its curious search for insects near the bottom of a tree, and ascending with jerks in a straight or spiral line to the top. Then, if it likes the tree, and thinks it a good place to stay a while longer in, the bird launches itself into the air, and drops down on wing, to begin another ascent, in preference to scrambling down again, as a woodpecker or nuthatch would do. The easy, gliding motion with which it climbs has deceived one writer into stating that the creeper does not hop along like a woodpecker; but, in fact, the movement is exactly the same in both cases. One of the English writers (Barrington, Zool. 2nd ser. p. 3998) describes, however, something peculiar in the position of the feet during the act of climbing:—These, he says, are not held parallel with each other, and near together, under the belly, but widely straddled, and thrown so far forward as to form with the end of the tail a surprisingly broad-based isosceles triangle. So nimble is the bird, and such a sly way has it of eluding observation by turning in the opposite direction to that in which a person moves to look after it, thus continually interposing the trunk of the tree in the line of vision, that it is no wonder the way it holds its feet long remained unascertained. Many things conspire to screen the queer little bird from any but the most patient and closest scrutiny during its ordinary vocations; and so nearly do its colours correspond with the tints of the bark that it is likely to be overlooked altogether. But its habits are so methodical and undeviating that when one has learned them there is no difficulty. If we see a creeper alight at the base of a tree on the side away from us, we have only to stand still, and keep a sharp look-out for it higher up; in a few moments, its spiral twisting will bring it round to our side; the chief point is to look high enough up, for it is surprising how rapidly the bird ascends. It generally makes the whole journey before dropping on wing to the base of the tree again, or making off to another; sometimes, however, the tree seems to be not to its liking, when, as if actuated by a sudden impulse, it abandons an unprofitable search, and flies to a more promising feeding ground."

This is a very fair sample of the author's style in treating of birds' habits, but many extracts would be needed to show the enormous pains he has taken with the more scientific part of the book. The array of references prefixed to the account of each species is almost appalling, but when we come to look into them we find these citations are not printed merely for the sake of giving an exhaustive list, but that there is a sufficient purpose for the insertion of almost each of them. In like manner we can praise the care bestowed on the technical characters of the several species, so far as we have been able to test them, for in diagnosis, that touchstone of a descriptive biologist, Dr. Coues especially shines, as indeed one expect might from the author of the "Key to North American Birds."

There is, however, one thing in this volume that we must say has excited our wonder, and must, we suspect, have deeply disturbed the minds of more than one naturalist who has read it. Dr. Coues, fully conscious of the risk he is running, cannot bring himself to reject the notion of Swallows and other birds plunging into the water in autumn and passing the winter in deep slumber! He admits that "it is as much as a virtuous ornithologist's name is worth to whisper hibernation, torpidity, and mud!"; but he adds further on, "It is not permitted to us, in the present aspect of the case, to rule out the evidence" in favour of what, for our own part, we must unhesitatingly call an exploded fable. It is certainly as much as a virtuous reviewer can do to treat this matter calmly. Yet we hold ourselves a better judge of evidence than Dr. Coues, and in spite of this singular aberration we draw our conclusion from the rest of his work that his reputation for sanity need not be thereby impugned. But he certainly overstates his case when he says that "the testimony, so far from ceasing with the irresponsible infancy of science, is reiterated to-day with the full voice of science, in terms that have not been successfully refuted." Now what is a successful refutation to one man, we all know, is not necessarily so to another. Are there not virtuous gentlemen who still insist on having proved the flatness of the earth, the squaring of the circle, and various geometrical impossibilities, and does not their very existence show that their testimony has not been "successfully refuted"? Nothing short of a miracle will convince some people, and we say this in view of both believers and unbelievers in the torpidity of birds. From whom is "the full voice of science" to be heard if not from scientific men, and where is the scientific man of to-day (Dr. Coues himself excepted) whose testimony reiterates that of Achard, Dexter, Pollock, Kalm, Forster, and the rest of those named in our author's excellent bibliography of the subject? We may have persons of intelligence and veracity, of respectability and honour, but we find not of late years one scientific man who can vouch for any statement of the kind on his own authority. It would be idle, however, to pursue the subject further; we should like to know, nevertheless, whether Dr. Coues refuses to reject the testimony as to the existence of Were-wolves, which seems to be on a par with, or even stronger than that in regard to, the torpidity of birds, and we shall only add that we think he is indeed "greatly mistaken" in his view that the Chimney-Swift (*Chætura pelagica*) "is not recorded as occurring anywhere beyond the United States in winter." If he will refer to a certain "Nomenclator Avium Neotropicalium," published not long since, he will find this species entered as occurring in Mexico, and we think we "could give reasons for the supposition" that it winters regularly in that country and others lying further to the south, instead of "hibernating in hollow trees" in the United States, so that what-

ever our author builds upon his basis would seem to have an unstable foundation.

We have just mentioned the excellent bibliography of the swallow-question given by Dr. Coues, but this is by no means the only one contained in his work. By way of appendix we have a "List of Faunal Publications relating to North American Ornithology," with a most useful double index (of authors and localities) thereto, the whole extending over more than 200 pages. The like of this we know not elsewhere, and we cannot sufficiently thank him for it. It makes us forget and forgive the single *escapade* which we so much regret having had to notice. One remarkable merit it possesses is that except in specified cases—and these, it is easy to see, are very few in number—no title has been taken at second-hand. More than this, we are told that the present batch of titles is but an instalment of a Universal Bibliography of Ornithology which the author has in hand, and towards which he has already collected about 18,000 titles! We are sure our readers will agree with us in hoping that Dr. Coues will be able to complete his laborious task, as well as in considering that its completion will redound to the already great credit of the department over which Dr. Hayden presides, and also to the medical staff of the United States army, which numbers Dr. Coues among its members.

BRITISH BURMA

British Burma and its People. By Capt. C. J. F. S. Forbes, F.R.G.S., M.R.A.S., &c. (London: John Murray, 1878.)

THIS book is offered as the result of thirteen years' experience derived from close intercourse, both officially and privately, with the people of Burma during that period. Such works are frequently contributed by the pro-consuls of the British empire, and afford, apart from their scientific value, good material to judge of the men and methods of our colonial government. Their merits are naturally unequal. The volumes of Raffles and Tennent, become classical, supply the corner-stones of future compilations, and are the exciting causes of a more ephemeral literature. It is, however, seldom that we see combined with the administrative capacities of our governors and commissioners a thorough knowledge of the ethnology, biology, and physical characteristics of the regions over which they preside. When such a man appears, and further possesses the quality of observation, his work marks an epoch, and English rule receives a new significance. It is in no adverse spirit that we say thus early that Capt. Forbes' work will not rank in this category, and we desire rather to commend it for what it does possess than to criticise it for the information which it does not supply.

Omitting the long narrow strip of mountainous country and sea-coast which forms the Tenasserim province below Maulmain, British Burma may, roughly speaking, be said to consist of three broad mountain ranges, having outside them on the west the sea-board province of Arracan, embracing between them the two great valleys of the Irrawaddy and the Sittoung, which forms, south of Rangoon, one vast plain, the centre range of the three mountain chains being shorter than are the other two. Its physical geography is interesting and peculiar, and in its pluvial character most characteristic and remarkable. The wet season lasts from about May to October, and during these five months of almost constant rain the average rainfall amounts to 184 inches at Maulmain,—in one exceptional year to 228 inches. During this period the great Irrawaddy rises 40 feet above its summer level and floods the surrounding lowlands, whilst its main current travels with a velocity of five miles an hour. Many proposals have been made to found sanatoriums for Europeans on the high mountain ranges of Burma, but however pleasant in summer, they would, says Capt. Forbes, "have to be abandoned to the jungle beasts and the elements during the rains, for not even natives could remain to take care of the buildings; and so incredibly rapid and luxurious is vegetation there, that the very next year a forest would have to be cleared away to find the houses again." December, January, and February are the cold months, whilst the hot weather lasts from February till the rains commence again. The climate, however, is excellent; the registration returns show that the deaths of children under five years of age are in the proportion of 27·85 of the total death rate; the percentage of children under twelve years of age is 35·8 of the whole population.

The chapter on the physical geography of the region is evidently compiled from careful authorities. The author appears to have undertaken no original investigations, nor to have added any original information on the subject; the biological effects of these annual inundations, in such a region teeming with animal life, excite the profoundest interest, but await the chronicle of a qualified observer. The principal part of the volume is occupied with an account of the people of British Burma, which the sociologist may find a storehouse of useful facts, and which must prove of the greatest value as an introduction to the ethnology of the region to all such as are approaching that subject. The statistical tables of the Census Report for British Burma, 1872, "give eighteen divisions of the indigenous races of so-called Mongolian origin." According to Capt. Forbes four great races occupy the Burman peninsula—the Mōn, the Karen, the Burman, and the Taï, or Shan, of which the Mōns form the majority of the inhabitants of British Burma. As regards the author's endeavour to give "a probable account of the route and order by which they arrived in their present localities," we must refer the reader to his arguments, and, without expressing an opinion thereon, will merely remark that even in science, when the rigour of induction is at all relaxed, a sentence written by Mr. Leslie Stephen is very applicable—"one clever man's guess is as good as another, whatever the period at which he lived." The chapters devoted to "social life and manners," &c., are very valuable to the comparative ethnologist. Some of these facts have been related before, but collected thus in a compendious form, and enriched with the results of a long official experience, they form material to supply links in that chain of generalisations which during the last few years in the hands of Tylor and Lubbock have created a new branch of anthropology.

Among the hill tribes the Karens are now divided between "those who have permanently settled in the plains and betaken themselves to a regular system of agriculture

and those who still remain in all their primitive freedom of the hills." This freedom, however, consists of a long and bitter struggle to raise their scanty crops on the hardly-wrought clearances of the virgin forest. Among the other enemies to their agricultural pursuits, Capt. Forbes mentions the visitations of vast hordes of "hill rats," which at long intervals of forty or fifty years settle on a tract of country for two or three years in succession, "till, like a swarm of locusts, they have reduced it to a desert." When on the move, in vast swarms, they cross the streams in shoals, so that the water is black with them, and from 1870 to 1874 they so devastated the hill country east of the Sittoung river that government was compelled to expend some 10,000*l.* in relieving the local Karen tribes.

The chapters upon Burman Buddhism must not pass without notice. Buddhism is not a subject quite suitable to the columns of NATURE, but there is exhibited in the short treatment of it such an intelligent appreciation of a vast system of philosophy, unaccompanied by narrow prejudice or preconceived ideas, as, if not perfect, proves the author to be capable of conducting investigations on thoroughly scientific principles.

W. L. D.

OUR BOOK SHELF

From Kulja, across the Tian Shan, to Lob-Nor. By Col. N. Prejevalsky. Translated by E. Delmar Morgan. With Introduction by Sir J. Douglas Forsyth, C.B. (London: Sampson Low and Co., 1879.)

COL. PREJEVALSKY has already proved himself one of the most scientific and determined of modern explorers, and has probably done more than any single man for an accurate knowledge of Central Asia. We have noticed in these pages his valuable work on his journey in Mongolia and Western China, and this narrative, short as it is, maintains the reputation he has already gained. The journey here described was made in 1876-7, and has been the means of clearing up several obscurities in the hydrography of the region visited. We have already, shortly after Prejevalsky's return, given the main results of the journey, from Kulja, south-east across the Tian Shan Mountains, by the Yulduz River, to the Tarim, and along that river to its termination in Lake Lob-nor, at the northern foot of the Altyn-tagh Range, on the 90th deg. of E. long., and just south of the 40th parallel N. Baron von Richthofen has endeavoured to prove that the present Lob-nor is not the Lob-nor of the old geographers, which he maintains was farther north. But to this Prejevalsky has an answer that it seems to us difficult to refute, notwithstanding that Richthofen probably knows more about the history of Central Asian geography than any one living. However the case may stand with regard to this, there can be no doubt about the value of Prejevalsky's observations on the present Lob-nor, which he states is fresh, shallow, almost overgrown with tall reeds, in the midst of which its strange mongrel inhabitants live, and of which they build their houses. The Altyn-tagh Mountains Richthofen considers the most surprising discovery of the Russian traveller, for it was generally supposed that there was an extensive tract of low country continuing through several degrees of latitude to the south of the lake. Prejevalsky's observations on the fauna of the Tarim and Lob-nor will be appreciated by zoologists, as will also his account of the wild camel. He has a special interest in ornithology, and above all in that department relating to the migrations of birds; and the part of his narrative which describes what he observed on this point during his stay at Lob-nor is one of exceptional value, and will, no doubt, be read with interest and profit by those who take an interest in the subject of migration. Mr. Delmar Morgan, who has made an excellent translation, has added to the brief narrative chapters on Lake Balkash, Lake Ala-Kul, and the Starovertsi, which, though somewhat irrelevant, are acceptable as being of real value. An excellent large map accompanies the volume, besides a smaller one, to illustrate the controversy between Prejevalsky and Richthofen.

A Manual of Practical Chemistry: The Analysis of Foods and the Detection of Poisons. By Alexander Wynter Blyth, M.R.C.S., F.C.S., &c. (London: Charles Griffin and Co., 1879.)

THIS work of 468 pages consists of two divisions, the first treating of the analysis of the principal articles of diet in daily use, the second of the detection and estimation of certain organic and inorganic poisons. The matter pertaining to the first division is further divided into seven parts, in which the different articles of diet are considered in their proper groups. These chapters are well and pleasantly written, bringing the information as much as possible up to date, and introducing where necessary modern methods of analysis. This may be seen in the chapter on sugars, where a full description of the optical method for the estimation of these bodies by the polariscope is given, with an accompanying diagram of the various parts, lenses, &c., of Soleil's saccharimeter. The remaining portions of the first division contain the matter concerning bread and flour; milk, butter, tea, coffee, cocoa, &c.; the chapter on tea and coffee containing a large number of analyses which no doubt will prove of great use. A considerable part of the book is devoted to the examination of alcohols, wines, and beers, in which instructions are laid down for the examination of such substances. In connection with this part the author gives a reprint of the tables introduced by M. A. Gautier for the systematic detection of colouring matters likely to be met with in wines, and gives an abstract of Gautier's paper containing the necessary instructions for the preparation of the sample, &c., to be examined.

The second division of the book contains the detection and estimation of the different poisons, the consideration of the organic preceding that of the inorganic. Although the information conveyed by the author is exact and well arranged with regard to the individual tests for each separate poison, it is to be regretted that he has not thought it necessary to develop more fully his remarks on a systematic course to be employed in the separation of the different poisons from each other. In many cases where doubtful evidence of poisoning exists a most exhaustive analysis is required, and we fear the general instructions laid down in the book for this purpose, or "method of procedure in analysis," as the author terms it, are somewhat insufficient.

The organic poisons and the detection of phosphorus are first taken into account in two divisions, first, those detected mainly by methods of distillation, and second, those separated for the most part by alcoholic solvents. The consideration of mineral poisons is placed last in the book, and contains the usual received tests for these substances, with in some cases a description of the body. With regard to this latter part we do not see why in a book published so recently as 1879 there are no remarks on the detection or separation of tin as a poison since it has been shown in letters to some of the journals that this metal may contaminate articles of food, more especially tinned fruits.

The work is clearly printed, but some of the diagrams are somewhat crudely cut, and if refinement in the arrangement of apparatus is intended in the illustrations, hardly carry out the intention; thus in Fig. 15 it is diffi-

cult to see from the drawing what is meant in the arrangement figured between the washing bottle and the French drying tube. There are some traces also of careless printing, which it would be well to rectify in future editions, as in the equation of the action of arseniuretted hydrogen on silver nitrate on p. 372. The title of the book is also somewhat presumptuous; it is styled "A Manual of Practical Chemistry:" the two last words being in large type; a colon is here introduced and then follows the exact title of the book in smaller type, "The Analysis of Foods and the Detection of Poisons." The work cannot be fairly described as a Manual of Practical Chemistry, and the title should therefore have been restricted to the matter actually contained in the book.

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts. No notice is taken of anonymous communications.*

[*The Editor urgently requests correspondents to keep their letters as short as possible. The pressure on his space is so great that it is impossible otherwise to ensure the appearance even of communications containing interesting and novel facts.*]

On the Spectrum of Brorsen's Comet

WITH reference to Prof C. A. Young's Note on the Spectrum of Brorsen's Comet, in NATURE, vol. xix. p. 559, it may be of interest to mention that observations made at the Royal Observatory, Greenwich, confirm his conclusion as to the coincidence of the brightest band in the comet spectrum with the green band of carbon.

We were not able to examine the comet's spectrum till April 17, as the Great Equatoreal was in the workmen's hands till that date for alterations required to allow of the more convenient use of the spectroscope. On that evening, and again on April 19, the comet's spectrum was repeatedly compared by Mr. Maunder and myself, with the spectrum of alcohol taken in a vacuum tube. The less refrangible edge of the brightest comet-band coincided as exactly as could be determined with the corresponding edge of the green carbon-band at 5,200, but the comet-band was very much wider, extending two-thirds of the way towards F (*i.e.*, about 200 tenth-metres), and covering the carbon-band at 5,200 (about 30 tenth-metres broad) and the two following fainter bands at 5,100 and 5,020. The comparisons were made on April 17 by the help of an occulting bar, and on April 19 with Hilger's bright-line micrometer, illuminated by red light. With the latter, readings for the comet- and carbon-bands respectively, agreed within half a tenth-metre. The half prism spectroscope with a dispersion of 10° from A to H (equivalent to two prisms of 60°) was used on the 13-inch equatoreal. From spectroscopic observations of the carbon compound, printed in the volume of Greenwich Observations, 1875, it appears that the bands in the spectrum of alcohol are identical with those in the spectra of olefiant gas, and of carbon oxide and dioxide.

A second band was seen in the orange of the comet's spectrum approximately coincident with the carbon band at about 5,600. This band was of about one-fourth the brightness of the principal band.

The results on April 17 were obtained without a knowledge of Prof. Young's work, and thus afford an independent confirmation of his conclusion. W. H. M. CHRISTIE

Royal Observatory, Greenwich, April 21

Blue Flame from Common Salt

I AM perfectly aware that, as Dr. Gladstone points out in your last issue, I have not *proved* HCl to be the origin of the blue flame, but I will give some of my reasons for *thinking* so.

In the first place I conclude every one will admit that chlorine in some form must be present, since only chlorides produce the flame. At one time I thought it was due to dissociated or atomic chlorine; that view, however, I discarded in favour of the hydrochloric acid theory.

When AmCl is heated, dissociation occurs, as is well known, NH_3 and HCl being formed; the HCl then plays its part in producing the blue flame. If calomel be used, it is natural to imagine that the mercury and chlorine are separated, and if the colour is due to HCl, the addition of hydrogen will be necessary before the flame is produced. As a matter of fact I have found that no coloration occurs if the calomel is heated in what I may perhaps be allowed to call the *solid* part of the Bunsen flame, *i.e.* where complete combustion takes place, but it is necessary to allow some of the unburnt gas to mingle with its vapour. In practice I adjust the wire gauze over the burner so that a black spot is seen surrounded by a red hot ring, a little calomel placed on the dark spot volatilises and colours the gas that is burning above the gauze; if the gauze is raised so that the dark spot vanishes and all is red hot, the salt volatilises without any coloration ensuing.

Although I have not been able to see any violet bands when a spark has been taken in HCl, I do not consider that it negatives my theory, since there is a considerable difference between an electric spark and a Bunsen flame, and I now have reason to think that under the influence of the spark the HCl is split up into its components, which will fully account for the absence of violet bands. I have likewise failed to get them from a spark in AmCl.

A drop of liquid HCl, introduced into a Bunsen flame by the aid of a platinum wire, gives a flash of blue colour, and a lighted taper immersed in a bottle of HCl gas has its flame surrounded by a blue mantle just before it goes out. The colour, to the eye, is identical in both cases to that produced by the volatilisation of a chloride, the peculiar violet tinge showing that it must contain rays of high refrangibility.

Lastly, if a stream of HCl gas be slowly passed into a large Bunsen flame, the colour is produced most vividly, the spectrum showing all the characteristic lines or bands. Here we have the HCl under the same conditions as the chloride and with a similar result.

Dr. Gladstone appears not to have obtained the flame by this method, since he says: "Hydrochloric acid passed into a flame never gives the violet light."

This may probably be explained by the fact that if the HCl be passed too rapidly the violet coloration gives place to green, similar to that produced by chlorine alone if the stream of gas be allowed to slacken, the violet is reproduced, and this may be repeated indefinitely. A. PERCY SMITH

Temple Observatory, Rugby, April 26

Did Flowers Exist during the Carboniferous Epoch?

ACCORDING to the position Mr. Wallace has taken in the discussion as to the order of insects to which *Breyeria borinensis* presumably belongs, everything depends upon the existence or non-existence of transverse reticulation. I re-assert that a regular and thoroughly well-marked transverse reticulation exists over all the wing.

If Mr. Wallace prefers to believe in the evidence afforded by a photograph in preference to my statement based upon actual examination, and to M. de Borre's words in his description ("Entre toutes ces nervures s'étend un réseau extrêmement complet de très-fines nervules allant transversalement d'une grosse nervure à l'autre"), it is evident that anything I could say would not alter his opinion.

Further, I utterly fail to comprehend by what process of reasoning he arrives at the conclusion that the photograph "is so beautifully sharp that it brings out the minutest details," when confessedly he has not compared that photograph with the original.

That the main nervures may be compared with some forms in Lepidoptera and found to agree to a certain extent is very possible; it would be singular if it were otherwise, considering the extreme variation in the neuration of Lepidoptera, and the practical certainty that the system of neuration in all orders of insects can be homologised. The presence of dense *transverse* reticulation in a lepidopterous insect would decidedly be an anomaly; but its absence would not prove that any particular fossil *did not* belong to the Ephemeridæ, for in some recent genera of the latter, such as Oligoneuria, Lachlania, &c., the transverse reticulation is so far absent as to be reduced to a few nervules that might be counted on the fingers of one hand.

Supposing, for the sake of argument, that my assertion may be based upon false premises (and no one is infallible), *Breyeria* would probably be relegated to that heterogeneous assemblage of extinct forms of insects possessing densely reticulate wings, to

accommodate which the order Palæodictyoptera has been formed. It is not for me to here enter into an examination of the materials included in this so-called order. It will suffice to say that not one of them could be suspected of being lepidopterous.

The point at issue is, did anthophilous insects (and therefore flowers also) exist during the carboniferous epoch? According to my views we are without evidence of their existence.

I decline any further discussion on this subject until Mr. Wallace has examined the fossil, or has obtained evidence of its peculiarities from some one in whose judgment he has more confidence than he apparently has in mine.

Lewisham, April 25 R. McLachlan

Captain Cook's Accuracy

In Nature, vol. xix. p. 408, there is an article entitled "Captain Cook's Accuracy," which I think reflects unjustly upon the late Admiral Wilkes, U.S.N. As a specimen of Wilkes's inaccuracy the writer of the article cites first the discrepancy in the position of Turtle Island, the south-easternmost of the Fiji group, Cook and Wilkes differing more than 30′ of longitude. The narrative of the U.S. Exploring Expedition was written on board ship during the progress of the work, and was placed by Wilkes in the hands of the printer immediately upon his return, in order that the general results might be known without delay. The astronomical positions were given as they were recorded at the time, and were not corrected for final chronometric errors and rates, which were carefully ascertained while the charts were being prepared for publication. A comparison of the narrative with the atlas, published subsequently, will exhibit differences of longitude almost throughout.

On the general chart of the Pacific, sheet III., which is on a very small scale, so that a slight inaccuracy of the draughtsman or engraver will cause a difference of several minutes, Turtle Island will be found to be in about 178° 22′ W. long., but the special plan of the island (vol. 2, p. 94, of the Atlas) places it in lat. 19° 47′ S., and long. 178° 16′ 18″ W., while Capt. Denham, R.N., in 1856, places it in 19° 49′ 11″ S., and 178° 14′ 42″ W., where it is at present shown on the British Admiralty Charts. The difference of latitude is about 1′ 45″; that of longitude, 1′ 36″; differences which might readily be accounted for by different points of observation having been used. The difference in the outline is not very material.

As Cook placed the Island in 178° W., he was fifteen minutes in error; while Wilkes differs from the latest surveys about a minute and a half. Capt. Worth, of H.M.S. *Calypso*, in 1848, placed the island in 178° 8′ W., differing seven miles from the subsequent survey by Capt. Denham, the position by the latter being now borne on the British Admiralty chart, yet the former authority is quoted to prove the inaccuracy of Wilkes's work.

Findlay, judging from what he says upon this subject, consulted Wilkes's book, instead of his chart, which was published subsequently. The second example of Wilkes's inaccuracy, cited by the writer, is that he found from a position which he occupied at Savaii, a trend of coast differing from that as shown by Wilkes's chart, but it is a question whether he was not mistaken in the identity of the point occupied by him. The waters of the Samoan group are, so far as we know, navigated safely and almost exclusively with Wilkes's charts.

The third and last example is concerning Quiros Island (Swain's Island). The facts in this case are that the boats of the exploring expedition did *not* effect a landing on the island at all; efforts were made to do so, but were unavailing on account of the surf, so that it is quite impossible that they could report the existence of a lagoon hid from their view by a wooded strip of land even if only a quarter of a mile in width.

In criticising the work of such explorers as Cook, Vancouver, and Wilkes, it should be borne in mind that the expeditions which they commanded were for exploring rather than surveying purposes, and it is rather a matter of surprise that they should have come so near the truth when we consider the crude materials with which they had to work. Sense of Force and Sense of Temperature

"J. T. B.'s" "discovery" of the distinction between muscular sensations—or, as he styles them, the "sense of force," whatever that may mean—and the sensation of temperature, has been long anticipated by Alexander Bain in his work on "The Senses and the Intellect."

Again, your correspondent's illustrations of the distinction he draws between absolute and relative muscular sensations and sensations of temperature are wholly illusory. How can it be said that a letter-sorter enjoys and improves absolute sensations of weight? Surely his sensations enable him to determine not "absolute weight" (whatever that may be), but the weights of particular letters relative to certain standards, according to which relation the postage is charged. These sensations enable him to say that certain letters are over, and others under, an ounce in weight, and thus they are in fact relative, not absolute, as "J. T. B." seems to suppose.

The same remarks apply to "J. T. B.'s" assertion that "the sense of temperature may also be rendered absolute to a certain extent," and to his illustration of the plumber who judges whether the heat of the soldering-bolt is adequate for his purpose. Here again the sensations are, in truth, purely relative, any inference drawn from them being based upon a comparison of present and previous sensations and present and previous experience of their results. Mark Lane, April 23

Mr. Preston on General Temperature-Equilibrium

My attention has been arrested by Mr. S. Tolver Preston's paper on general temperature-equilibrium in Nature, vol. xix. p. 460, and by a letter from him in a later number (p. 555), pointing out a trifling literary ambiguity in it. As this implies that the paper is otherwise correct, you will perhaps allow me to protest, and to state that it is full of confusion of reasoning and of unsoundness.

I do not know how many sins against dynamics could be discovered by careful examination, but at least two pervade it throughout, viz. (1), the assumption that the simple relationship which exists between the movements and the temperatures of molecules of matter exists also between the movements and the temperatures of masses of matter; (2) the assumption that gaseous molecules (simple or compound) whose bond is chemical affinity differ mechanically from masses of matter (stellar or otherwise) in size and weight only, whereas they really differ in a multitude of other ways, and notably in elasticity; and from this difference alone it would be easy to show that the analogy in the paper is fanciful, and its reasonings and conclusions invalid, but I respect your space.

In conclusion I would say that I am not writing against the hypothesis of temperature-equilibrium itself. It may or may not be true. All I assert is, that this paper gives no real information about it. Wm. Muir

The Migration of Birds

It was becau e Prof. Newton mentioned such distances as six, seven, and ten miles (*vide* Nature, vol. xix. p. 434), in connection with the flight of migratory birds, that I brought forward the matter of temperature, and the latter still appears to me to have as much bearing on the question, as has the density of the atmosphere.

The intense frost on Christmas eve, 1861, was said to have killed a large number of thrushes, blackbirds, &c., in Scotland. Near Edinburgh, where the thermometer registered about $-4°$ F. during the night, many dead birds were found. These deaths resulted from cold, not from starvation, for the weather was open until within a few days of Christmas day. Now, if a frost of this severity has such an effect on bird-life, surely it must be conceded that temperatures from $-25°$ to $-100°$ F.—those that would reign between six and ten miles' elevation, with surface temperature of $+80°$ F.—would slay the hardiest migrant.

There is a great difference between the elevation required to view a distant sea horizon, and an equally distant mountain-top. For instance, to obtain a sea-horizon of 300 miles, you must mount nearly twelve miles; but from an altitude of four miles, the summit of a mountain 20,000 feet high (less than 4 miles) would be visible, though its base lay 300 miles off. Similarly, if an elevation of 5,000 feet only be granted to the haze that constitutes the loom of land, birds flying two miles high will have a circle of vision, for the land indication, of over 200 miles radius. Under such circumstances, if the journey is 1,000 miles in length, a deviation of some 12° on either side of the true direction of flight

can be made by migrating birds, without leading them out of view of their destination. With shorter journeys it is evident the error of flight may be largely increased without endangering the safety of the migrants.

Migratory birds that are strictly nocturnal cannot cross any very great expanse of barren ocean, hence, unless their error of flight is large, and the land they wing their way to small, there is not much fear of their losing themselves. Moreover, if they do go wrong, dawn must assuredly bring back their powers of vision.

Beckenham, April 27

An Observatory of Newton's?

THERE is a tradition associated with a domed building, now covered with ivy, situate on Stamford Hill, that it was once employed as an observatory by Sir Isaac Newton. Can any of your readers give any information upon the subject? Immediately beneath the revolving dome there is a well-shaped excavation (now partially filled with water) in which is an extinguisher-shaped stand, supposed to be of iron; this may have formed part of the base of a telescope, but no information upon the subject can be obtained from the local inhabitants.

Waterton's Wanderings—Goat-suckers

ONE would like further information respecting the "nocturnal flies" which settle on the udders of cows or goats, and may be seen on moonlight nights. Many lepidoptera and coleoptera and a few hymenoptera are nocturnal, but are not known to adopt the habit described. Of the true flies, diptera, are any nocturnal?

HENRY H. HIGGINS

A STATUE TO CAPTAIN COOK

THE Australians have found a hero worthy of their worship, and Capt. Cook has at length found an English-speaking people eager to take occasion to honour the memory and the work of one of the greatest of Englishmen. The mystery of the reticence of our wealthy but unwieldy Geographical Society on the occurrence of the centenary of Cook's death, still remains unsolved; they did not even send a representative to Paris, to the amazement of the enthusiastic French geographers; was the weather too rough for the gallant admiral who we believe volunteered to the indifferent Council to go to the Paris meeting? We are glad for the credit of the nation that it has not been left entirely to the foreigner to recognise the greatness of one of England's greatest navigators and discoverers. Our readers may remember that some time since a statue of Cook adorned Waterloo Place, near the Athenæum Club. The statue was admitted to have been exceedingly happy in conception, and successful in execution; it is supposed to represent the great navigator coming within the loom of the east Australian coast, which he first saw near Cape Howe, to the south of Sydney. It was for this city that the statue was designed, and it was to inaugurate the work of Mr. Woolner, that on February 25 last one of the greatest demonstrations took place that has been witnessed in Australia since the first shipload of convicts was landed at Botany Bay. When we said that Australia had found a hero, perhaps we spoke too widely, for only New South Wales as represented by Sydney, seems to have joined in the demonstration to commemorate the centenary of Cook's tragic end and the unveiling of his statue. It seems to us a great thing for a people to have a worthy national hero, and since the days when Abraham begat Isaac, and probably long before, every nation of any note has had its hero or demigod in whom all the national virtues have been embodied. The Australians have the making of a great people among them, and while they have a right to count our gods as theirs, still no doubt they would like to have a Hengist of their own to mark a new starting-point in their history. Happily, as we have said, they have found a worthy one—one whose character is in every respect worthy of their admiration, and the principles of whose conduct, if adopted and acted upon, will help to make of them a really great people. However desirable we may think the federation of our Australian colonies to be, any advocacy of it in these pages would be out of place. Still we cannot but think that it would have been a good thing in many ways—a good thing for the colonies themselves, and conducive to cordiality among them—had they all united to do honour to one so worthy of honour in all respects, and to whom, in a sense, they are indebted for their very existence.

Nothing could have been more successful than the gathering in Sydney on February 25, to assist at the unveiling of the statue by Sir Hercules Robinson. It was a universal holiday. Probably there were not much less than 100,000 people gathered in and around Hyde Park at the time of the opening ceremony—people of all classes who had voluntarily given up their work or business for the day, apparently, to a large extent, from genuine enthusiasm towards the man who first landed near the site of what in a few years has become one of the finest cities in the world. The statue seems to have given universal satisfaction, and the enthusiasm reached its height when Sir Hercules Robinson unveiled it at the conclusion of a solid and suitable speech. In his address the Governor traced in a sympathetic manner the career of the hero whom they had gathered to honour, from his birth as a peasant's son, till his unfortunate murder at Hawaii. Sir Hercules does not, however, seem to be well up in the latest evidence with regard to Cook's death, and seems, as of old, to have attributed it to mere savagery, whereas it seems pretty clearly ascertained that it was a blunder on the part of the poor natives. We have so recently written on the character and work of Cook, that it is unnecessary again to go over the same ground. Sir Hercules very happily, we think, read the moral of Cook's life to the people of Sydney. He was a man who eagerly pursued knowledge as his scanty opportunities afforded: who valued science, and endeavoured to do all his work by its light and guidance; who treated those under his command with the greatest consideration, and exercised the utmost tenderness and humanity towards the natives of the various islands with which he had any dealings. "Such a statue is creditable to ourselves," Sir Hercules justly concluded, "as marking our admiration of the character and services of the man, and our gratitude for the benefits which his discoveries have conferred, not only on Australia, but also on the world at large. . . . There is scarcely a lad born in this country who has not within his reach educational advatages superior to those which were available to the poor Yorkshire peasant boy, and I hope that the history of his early life may not be thrown away upon the young, but that many a child in the future will learn at the foot of this statue how a faithful, patient, cheerful attention to the details of daily duty, however monotonous and commonplace, will bring its own reward, and may perchance, as in the case of James Cook, leave behind a noble and imperishable memory."

While we regard it as right and proper that this fine statue should have been erected in Sydney to Cook, we think, moreover, the people of New South Wales would only be carrying out the work of Cook if they took some step to obtain a more thorough knowledge of these Pacific islands and seas, for a knowledge of which Cook did so much. We recently referred to the lecture given them by Dr. Miclucho Maclay on the want of a zoological station at Sydney; and we would suggest that the people of Sydney, helped by the other Australian cities, should carry out the work they have so well begun, by founding an institution, that under proper guidance would add immensely to our knowledge of the life of these interesting

waters. Meanwhile let us be thankful that they have done something to redeem the race to which Cook belonged from the charge of insensibility to his greatness.

THERMO-CHEMICAL INVESTIGATION

THE introduction of a new method of research, or the invention of a new instrument, has repeatedly marked an epoch in the development of more than one branch of natural science. The last few years have witnessed the introduction into chemical research of a new method of examining chemical changes, a method which is founded upon the study of those thermal reactions which accompany these changes.

The older methods of chemical investigation failed to throw any definite light upon many important problems, some at least of which have been brought a step nearer complete solution by the application of the newer method of thermo-chemical measurement.

When solutions of two salts are mixed, the products of the mutual action of which salts remain in solution under the experimental conditions, it is frequently found impossible to determine, by means of the ordinary analytical processes, the chemical distribution of the mass of reacting matter at the expiry of the experiment.

Again, there are certain acids which undoubtedly form two series of well-marked salts, but which appear to be capable, under certain ill-defined conditions, of forming a third series of unstable saline derivatives. How to determine the basicity of such acids has long been one of the unsolved problems of chemistry.

Once more, the ordinary methods of investigation have failed to supply us with any far-reaching generalisation concerning the stabilities of series of compounds. Certain relations have undoubtedly been traced between general chemical properties of compounds, the properties of their constituent elements, and the stability of these compounds, but, nevertheless, the shadowing forth of well-marked generalisations, connecting stability of compounds with chemical structure, from which generalisations exact deductions, capable of experimental investigation, might be made, dates from the introduction of the thermo-chemical method of investigation.

That system of notation which is now employed in chemistry, although of the greatest value, is nevertheless far from being perfect; it fails to tell anything concerning the changes in forms of energy involved in those changes of distribution of mass which it formulates. Previous to the introduction of the thermo-chemical method little or no exact knowledge regarding these changes of energy was in the possession of chemists.

Chemists were long aware that certain reactions were possible only under stated conditions of temperature, pressure, &c., but until measurements had been made of the amounts of heat evolved or absorbed in these reactions they were unable to generalise the connection between the conditions of the reactions and the possibility of their occurrence.

Such are some of the problems which have been at least partially solved by the new method.

The fundamental position of thermal chemistry may be thus stated: "Every chemical change taking place without the aid of extraneous forces tends to produce that body, or system, in the formation of which the greatest evolution of heat occurs."

As a deduction from this statement Berthelot formulates his law of maximum work as follows:—"That salt, the formation of which is attended with the greatest evolution of heat, is always produced when those salts, from whose mutual action it may be formed, exist in solution in a condition of partial decomposition."

Many special instances illustrative of these generalisations might be cited; let one or two suffice. Chlorine decomposes dry sulphuretted hydrogen with formation of hydrochloric acid and separation of sulphur; iodine does not decompose sulphuretted hydrogen under the same conditions. The formation of hydrochloric acid and sulphur in the first change is accompanied with the evolution of a considerable quantity of heat; the formation of hydriodic acid and sulphur, in the second case, would involve the absorption of much heat. If, however, the action of extraneous forces be allowed to supervene, a new condition of equilibrium is attained; add water to sulphuretted hydrogen and iodine, hydriodic acid and sulphur are produced. But the solution in water of hydriodic acid, which is the potential product of the reaction, involves the evolution of more heat than is absorbed in the reaction itself.

Iodine scarcely decomposes water, but if sulphurous acid be added to water, iodine is capable of bringing about decomposition, the products of the reaction being hydriodic and sulphuric acids

$$(H_2O + I_2 + H_2SO_3 = H_2SO_4 + 2HI).$$

Now it is found that the formation of sulphuric from sulphurous acid is accompanied with the evolution of a considerable amount of heat; if, then, the decomposition formulated $2H_2O + 2I_2 = 4HI + O_2$ be started, the combination of the oxygen thus produced with the sulphurous acid present causes the evolution of more heat than would be evolved in any other series of chemical changes which could occur among the bodies present.

The applications of the thermal method in general chemistry are many and important. I propose briefly to consider some of the results obtained by this method, as shown in the phenomena attending the neutralisation of acids; in the changes which occur on mixing solutions of two salts which are capable of undergoing decomposition with the production of salts themselves soluble under the conditions of experiment; in the measurements of (so-called) affinities between elementary bodies; and in one or two other reactions of general interest.

The neutralisation of an acid by an alkali is attended with the evolution of a constant amount of heat; in some cases it is noticed that the total amount of heat evolved is independent of the relative quantities of acid and alkali employed, while in other cases the total heat evolution may be divided into two equal portions, one half of the whole accompanying the addition of the first portion, and one-half accompanying the addition of the second portion of alkali. Those results evidently point to the exhaustion of the available energy of the acid (or alkali) as a phenomenon which takes place in regular stages. The thermal results of neutralisation phenomena are rendered more intelligible when we find that an acid, the neutralisation of which is accompanied with the evolution of but one quantity of heat, is also a monobasic acid; while in the case of a dibasic acid the total amount of heat evolved on neutralisation with alkali is divisible into two distinct portions. Further, a difference is traceable between the thermal phenomena which attend the neutralisation of an acid by caustic potash or soda, on the one hand, and by ammonia on the other.

The reaction formulated

$$2KHO + H_2SO_4 = K_2SO_4 + 2H_2O,$$

involves the expenditure of 31,000 thermal units; but the reaction $2NH_3 + H_2SO_4 = (NH_4)_2SO_4$ is attended with the expenditure of but 28,150 thermal units

If, however, a compound more strictly comparable with caustic potash in its chemical structure be employed to neutralise sulphuric acid, we find that the heat evolved is equal in both cases; the reaction

$$2N(CH_3)_4OH + H_2SO_4 = (N(CH_3)_4)_2SO_4 + 2H_2O,$$

is attended with the evolution of 31,300 thermal units.

From the point of view of their thermal reactions, the alkalis (including thallium hydroxide) and the alkaline earths, are strictly equivalent, so far as the power of

neutralising one and the same amount of sulphuric acid is concerned.

The effect of substituting various compound radicles for the hydrogen of ammonia, is well shown in the phenomena attending the neutralisation of acid by ammonia, and by those substituted products. The introduction of a C_nH_{2n+1} group (C_2H_5, CH_3, &c.) into the ammonia molecule produces a substituted ammonia, the heat of neutralisation of which is the same as that of the parent body; but if a negative radicle (such as C_6H_5) be substituted for hydrogen, then a compound is produced in the neutralisation of which less heat is evolved than in the neutralisation of the parent body. Thus the neutralisation of hydrochloric acid by ammonia is accompanied with the evolution of 24,540 units of heat, while the neutralisation of the same acid by aniline ($NH_2C_6H_5$) is accompanied with the evolution of only 15,000 to 16,000 thermal units.

When solutions of two salts are mixed under conditions such that the products of their mutual action remain in solution, thermal measurements throw very considerable light on the progress of the chemical change.

The problem presented by the phemonenon now under consideration is one of those which are peculiarly difficult of attack by the older methods. If a third body were introduced into the mixture of salts, which should combine with, or render insoluble, one or more of the possible products of the action, a new configuration would be initiated, new chemical changes would probably occur, and we should be unable to say whether the results obtained were really trustworthy representations of the action which had taken place between the members of the original system.

But measurement of thermal changes involves no disturbance of the equilibrium of the reacting chemical system, and at the same time it yields trustworthy information regarding the changes which have occurred in the distribution of the mass of matter comprising that system. To take an example:—On adding a solution of potassium chloride to dilute hydrochloric acid no thermal change is noticed; on adding a solution of potassium sulphate to dilute sulphuric acid heat is absorbed, the amount of heat so absorbed increasing with the amount of acid added, until a limiting point is reached. If the solution of potassium sulphate be made more and more dilute less and less heat is absorbed. Now these facts evidently point to the occurrence of two processes of chemical change in the above reaction, viz., the direct action, formulated $H_2SO_4 + K_2SO_4 = 2KHSO_4$; and the inverse action, formulated

$$2KHSO_4 + H_2O = K_2SO_4 + H_2SO_4 + xH_2O$$

We are thus taught to regard this chemical change as dependent on the conditions of the experiment, and further we obtain a glimpse of the decompositions and recompositions which are continuously occurring among the molecules of our seemingly stable compounds.

If solutions of zinc acetate and sodium sulphate be mixed no thermal change is noticeable, but if solutions of zinc sulphate and sodium acetate be mixed, an evolution of heat occurs, that is to say, a chemical change (or a series of chemical changes) proceeds. Such an experiment as this, besides throwing light upon the special chemical change under consideration, leads to a clearer conception of those phrases "strong acid," "weak base," than were generally to be found before the introduction of the thermal method into chemistry. A strong acid is evidently an acid in the formation of the salts of which much heat is evolved, and a weak acid is one in the formation of whose salts little heat is evolved, or heat is absorbed. If therefore the heats of neutralisation of two acids by given bases be known, it may become possible to predict what chemical changes will occur when given salts of those acids are mixed.

Attempts have been made from time to time to measure the so-called affinities of the elementary atoms. These attempts have been considerably advanced, and the whole problem of affinity has been much defined by applying the results of thermal measurements to chemical reactions.

If chlorine be mixed with hydrogen, and the mixture be exposed to daylight, hydrochloric acid is produced with evolution of a large amount of heat; the formation of hydrobromic acid from its elements is accompanied with the development of less heat, while heat is absorbed in the formation of hydriodic acid from its elements. These thermal reactions show that more energy changes form in the first than in the second, and more in the second than in the third of these reactions. The amount of energy of motion which is convertible into thermal energy, under fixed conditions, seems, therefore, to measure the mutual affinities of chemical elements.

But we do not know what is the amount of energy spent in decomposing the molecules of hydrogen and chlorine; the heat developed in the reaction

$$2H + 2Cl = 2HCl$$

is therefore the sum of the plus and minus thermal changes during the cycle of chemical changes, the initial and final stages of which are chlorine and hydrogen molecules and hydrochloric acid molecules respectively. Therefore it is evident that thermal measurements do not give data which suffice for determining the absolute affinities of the elements.

If the elements comprised in a natural group be converted into similar compounds—say into oxides—and if that element in the formation of whose oxide the greatest amount of heat is developed be said to have the greatest affinity for oxygen, many remarkable relations may be shown to exist between the affinities and the atomic weights of the elements in such a series. Thus Thomsen has shown that in the group comprising magnesium, calcium, strontium, barium, the affinity for chlorine, bromine and iodine increases with increase of atomic weight, while the affinity of the haloid compounds of these elements for water decreases as the atomic weight of the elements increases. Many more exceedingly interesting results are brought out by Thomsen in the same paper.

The results of thermo-chemical investigation—a few of which I have endeavoured to sketch in thinnest outline—suggest one or two considerations regarding chemical action in general, and regarding some of those problems which yet remain to be solved by chemical science.

The older theory of chemical action is based upon the idea that the reacting bodies exert force upon one another; the word affinity has thus a positive meaning.

Recently the view has gained ground, with some chemists, that a chemical change is but the outward representation of a loss of energy occurring within the reacting system; that no positive force is exerted between the reacting molecules, but that the system, as it were, falls to pieces because the conditions are realised under which a loss of energy is possible.

The latter view, I think, fails to account for the facts; there is no doubt that it expresses a truth, but surely only a partial truth.

General considerations, no less than those derived from thermal measurements, compel us to regard the first action between two elementary molecules as consisting in a decomposition of those molecules with the production of their constituent atoms, which afterwards combine with the formation of new molecules. But the decomposition of elementary molecules involves the expenditure of energy; in other words, there is a mutual action and reaction between these molecules. If this stress be regarded from the point of view of one set of the reacting molecules only, we certainly have positive force exerted.

It is not a mere negative loss of energy, but a positive action of one kind of molecules upon another kind of

molecules; and the amount of force exerted is different for different elementary molecules. Hence chemical affinity is a positive force. The mutual action and reaction between the molecular systems involves the loss (or gain) of energy, but this loss of energy does not furnish a complete account of the action.

Thermal measurements enable us to determine the quantity of energy entering or leaving a given chemical system during its passage from one state to another. These measurements, therefore, give us most valuable information concerning the phenomena exhibited by those chemical systems.

The results obtained by these measurements show how great is our ignorance with regard to the progress of chemical reactions in general; and they suggest many exceedingly interesting problems which will doubtless ere long meet with satisfactory solution. The great problem of chemistry is to determine the connection between the structure and the properties of molecules. To take a special case, it may be asked, why is the hydrogen of acids replaceable by metals under definite conditions? Many facts are known which enable us to give partial answers to this question; doubtless, thermal investigation, taken in conjunction with other methods of research, will some day furnish the complete answer.

Thermal measurements have already shown us that allotropic changes in elementary molecules are accompanied with changes in the energy of these molecules and that the same generalisation holds good with regard to isomeric changes among compound molecules. But the whole question of allotropy is yet in its infancy.

The thermal method promises to throw light upon those phenomena which are classed together under the name of valency, and perhaps to furnish an answer to the query, *why* does the valency of elementary atoms vary? The new method is full of hopeful anticipations.

M. M. PATTISON MUIR

ARE THERE NO EOCENE FLORAS IN THE ARCTIC REGIONS?

IN NATURE (vol. xix. p. 124) I expressed doubt whether the beds containing fossil plants in or near the Arctic circle, said by Heer to be miocene, are really of that age. It seemed to me then very probable, but now I may say certain, that at least all those said to be *lower* miocene are truly eocene. The article was translated in *Das Ausland*, No. 2, 1879, and replied to by Heer in No. 8 (February 24) of the same journal. In this reply he, as I expected, combats my views, and, although affecting to believe that I had written without thought or previous study, he devotes eight columns to contradicting me, yet without bringing forward any fresh evidence whatever, or indicating any sources of information which I had not already consulted.

Heer contends that all the known fossil floras containing dicotyledons, from all lands within at least 2,000 geographical miles of the Pole, are either cretaceous or miocene. I think, on the contrary, many of them are eocene.

The leading facts for and against the hypothesis of a miocene age for so large a proportion of them may be briefly summarised.

1. The great similarity of the floras (miocene of Heer) of latitude 70° to those of 47° and 46°, 98 species out of 363, or more than 25 per cent. being common to both, even in the present state of our knowledge. This, according to existing plant-distribution, precludes their being of the same age, unless the more southern ones grew in Alpine or even hilly regions; but no one has ever contended that they did do so. No floras so much alike, and assimilating so closely to those of the present day, could have grown simultaneously at the same level in such widely different latitudes.

Against this Heer states that a number of trees extend from the borders of Italy to the 70th parallel, as the firs, birches, aspens, bird-cherry, and mountain-ash. This fact has little bearing on the subject, since the trees are Alpine, or, at least, not in any way characteristic of the lowland flora of North Italy or of that latitude in Europe. Secondly, he says that of the fifty-nine phanerogams found by Feilden in Grinnell Land between 81° 44′ and 83°, forty-five are European, and six of these are not only found in Swiss valleys, but also in Italy. This should not have been advanced, being quite beside the question, unless he wishes to make believe that the present floras of Grinnell Land and Italy resemble each other. They are, in fact, all Alpine herbaceous plants, and have nothing to do with the fossil *forest* floras in question; besides which, the level of the Swiss valleys in which these six grow is not stated, and there is nothing curious in Alpines ranging into Italy. Thirdly, of 559 species of phanerogams of the Isle of Saghalien, 188 are found in Switzerland. Such occasional examples of wide lateral distribution among plants are well known, and might often be adduced, without affecting the question in the remotest degree. The present distribution of the *same* types of plants, trees, &c., as those which are found fossil, have alone any bearing on the subject. Heer, to sustain his theory, must prove that forest floras extend in some other parts of the world with a much less degree of change than we have experience of in ou rcontinent, over not less than 30° of latitude, and in about the same longitude.

2. The extreme improbability that the plant remains of the eocene, a far more important formation than the miocene, should have been alone overlooked in a series of deposits abounding in plants of immense extent and thickness, and continuous, it is supposed, from the middle cretaceous to the upper miocene. The absence of any intelligent explanation of the complete break in the sequence, which Heer's nomenclature implies, and of which there is not the least stratigraphical evidence. The vastness and immense extent of the formations which are ascribed to miocene. The universally admitted fact that continuous land existed in the north between Europe and America from early eocene times, as proved by the palæontological records of both continents, and supported by other considerations, and which must have left records at least in proportion to those of the miocene, since volcanic, the preserving agency, was active throughout the whole time.

Heer characteristically meets these important objections by stating that at Eisfiord, in Spitzbergen, there are 1,000 feet of strata between the cretaceous and miocene, which he thinks doubtless represent the eocene. It is strange to find any one with the least knowledge of stratigraphical geology simple enough to advance such evidence as the presence of 1,000 feet of beds at a single spot, in dealing with so colossal an interval as that between the cretaceous and miocene, especially when the latter alone, over the area, is several thousands of feet in thickness. Besides Nordenskjöld,[1] from whom Heer derives his information, says that the miocene (of Heer) habitually rests upon the cretaceous.

Heer further says that there is a deposit with lower miocene mollusca under a miocene deposit. This is exactly what I should expect; for the same reasons that make it improbable that the flora is miocene apply equally to these mollusca.

3. The much higher temperatures which prevailed in the eocene than in the miocene, and which could only have permitted the growth of such temperate floras in such high latitudes in the eocene period, according to existing laws of plant distribution.

Although I showed *seriatim* that a mean temperature higher by 20° F. in the northern hemisphere would inevitably have produced approximately just the series of

[1] Excursion to Greenland, *Geol. Mag*, vol ix.

eocene floras that are met with in England, Iceland, Greenland, Spitzbergen, and Grinnell Land, and that from Heer's miocene standpoint no uniform increase could do so, his eight columns of reply do not embrace this question.

4. The total absence of any characters among the plants themselves, which would preclude their being considered eocene.

To this I must also await an answer until eocene floras are better understood. Heer's reply contains none.

It is obvious that if he has no more to say than this, the balance of the evidence, even as it stands, is already actually against him. But it is far more conclusive than I have represented it to be in the above summary.

We are told to believe that enormous deposits, many thousand feet in thickness, vast in extent, and resting everywhere conformably on the latest cretaceous beds, and indeed stratigraphically indistinguishable from them, are not as we should expect, in greater part at least—the next succeeding older tertiaries, but *the miocene*. We are not to question the reality of the marvellous gap thus created; not to point out that climatic considerations are entirely against the miocene age of the beds; not even to suggest that the plant evidence relied upon quite fails to support it; for Heer, like an infallible Pontiff, has, *on plant evidence*, pronounced them miocene.

He has tried to excommunicate me in his concluding paragraph, of which the following is but a feeble translation:—"The incorrect assertions and conclusions of Mr. Gardner proceed from want of knowledge or disregard of well-ascertained and solid facts, and it is much to be desired that those who occupy themselves with such difficult questions should first acquaint themselves with the facts before they express upon them such positive opinions."

I, however, to use a quotation, do not feel "one penny the worse."

The miocene hypothesis, which is not a scientific one, and would have been gladly overturned by Belt, rests entirely upon Heer's interpretation of the plants. I have therefore, I presume, but to show how completely unreliable in this case Heer's interpretation is, to break the spell of infallibility attaching to his work and to reopen the question for solution by scientific thought—"the application of past experience to new circumstances, by means of an observed order of events," as Clifford put it. In the first place, what are the "well-ascertained and solid facts" of Heer? I have looked at the Bovey Tracey beds formerly described, and erroneously, as miocene by Heer. Taking the ferns, with which I am just now most familiar, I find a form described as *Pecopteris lignitum*, and this species was at the time no doubt a "solid fact;" but I subsequently find Heer describes this *same* fern as *Aspidium lignitum*[1] and, extraordinary to relate, as *Dryandra rigida*.[2] Are these solid facts? Because he how speaks of the species as an Osmunda. I might analyse Heer's "solid facts" to a considerable extent, but refrain from doing so until the proper time arrives, in the pages of the Palæontographical Society. In the meantime I cannot but consider that his caution might more justly be applied to himself; for whilst I, at least, have had access to all Heer's published facts, I expressly stated that those I chiefly relied upon were unpublished.[3] I therefore marvel that he should have written so positively on so difficult a question without first, at least, endeavouring to acquaint himself with the latest facts.

Heer either does not possess, it appears, the knowledge requisite to separate stages of the eocene from the miocene, or he misapplies it. Of all the floras he has described but one is for him, eocene, and about this he expresses the greatest doubt. This single "great work"[1] on the eocene, as he calls it, was no larger than could be amply illustrated in ten not over-crowded plates, for I find the same species doing duty on more than one under different names. Beyond this he only claims to have studied the flora of Monte-Bolca, although he has published nothing upon it, and to have seen "many plants of the English eocene." Of the Monte-Bolca flora I can say little, as when I have been to Verona, where, I believe, large collections exist, the curator has been absent; but of the latter I can say that Heer's "many" must be used in a limited sense, for when he visited England, before either Mitchell or myself had commenced collecting, the collections open to him were meagre indeed.

Although, however, Heer modestly claims to have described but one eocene flora, I believe credit is due to him for describing several. Among these the most familiar to us is that of Bovey Tracey, lithologically and palæontologically precisely resembling some of the middle eocene beds of Bournemouth, only eighty miles distant from it.[2] Heer may, of course, deny their eocene age, and I cannot convince him by letting him see the specimens, as I did Ettingshausen, who, after being shown leaves, fruits, seeds, and spines, said the matter must be considered doubtful unless I could produce *Sequoia Couttsiæ* from Bournemouth. This, on looking through the cabinet of conifers, we found in abundance, not only from Bournemouth, but also from Alum Bay. This is but one instance selected from near home. If we look at Heer's tables in the third volume of his "Flora Tertiaria," we see that all the floras of France, Germany, Austria, Italy, and Switzerland are called miocene. The floras of Sotzka, Häring, Monte Promina, &c., although eocene to those who described them, are not so to Heer. He, in fact, persistently misrepresents the relative importance of the eocene and miocene formations, which he has always reversed, almost ignoring, indeed, the existence of the far more important of the two. Fortunately, accident has given to me what it has denied to Heer after a life of study, that is, access to large series of undoubted middle eocene plants; for my own collection, from Bournemouth alone, cannot number less than 10,000 selected specimens. These plants reveal how closely many of Heer's so-called lower miocene floras assimilate to the eocene, to which age they doubtless belong, and that forms thought to be characteristic of the former are really only met with in the latter, and that other species, ranging through both, are misleading and negative, so far as affording evidence upon this question. Of course Heer could not be acquainted with the unpublished English floras, and unfortunately their publication must be a work of time; but why, for example, in opposition to Unger and Ettingshausen, did he maintain the Sotzka, Häring, and Monte Promina floras to be miocene.

"When next you view,
Think others see as well as you."

is the moral of a fable with which Heer seems unacquainted.

I know that in very many cases what is lower miocene to Heer, is lower or middle eocene to me, and that therefore his *lower miocene* floras are practically and truly my *middle* or at latest *upper eocene* floras. There is thus a great difference of opinion between us, for the one nomenclature often implies immense gaps, which the other fills up.

While Heer's opinions of the ages of his localised floras are mostly based upon the evidence of the plants themselves, and the beds in which they are found contain little or no internal evidence, apart from this, of the formations to which they belong—those upon which I am

[2] *L.c.*, pl. x. f. 15.
[3] In course of publication by the Palæontographical Society.

[1] "Der sächsisch-thüringischen Braunkohlenflora," Berlin, 1861.
[2] *Geol. Mag.*, April, 1879.

at work are upon stratigraphical evidence *certainly* of the ages to which they are ascribed.

We have a limited Thanet sand flora; a considerable insight into the Woolwich and Reading Beds flora, obtained from Dulwich, Reading, Newhaven; an Oldhaven flora from Bromley; an extensive London clay flora from Sheppey; a Lower Bagshot flora from Alum Bay, Studland, and Corfe; a Middle Bagshot flora from Bournemouth and Bovey Tracey; upper eocene floras from Hordwell, Gurnet Bay, &c. All these will be embraced in the monograph now in course of publication by Ettingshausen and myself.

The nearly unbroken sequence seen in the eocene floras extends into the miocene. There is no great break in passing from one to the other when we compare them over many latitudes, and but little change, beyond that brought about by altered temperature or migration. If tertiary floras of different ages are met with in one area, great changes on the contrary are seen, and these are mainly due to progressive changes in climate. From middle eocene to miocene the heat imperceptibly diminished. Very gradually the tropical members of the flora disappeared; that is to say, they migrated, for most of their types, I think, actually survive at the present day, many but very slightly altered. Then the sub-tropical members decreased, and the temperate forms, never quite absent even in the middle eocenes, preponderated. As decreasing temperature drove the tropical forms south, the more northern must have pressed closely upon them. The northern eocene, or the temperate floras of that period, must have pushed, from their home in the far north, more and more south as climates chilled, and at last in the miocene time, occupied our latitudes. The relative preponderance of these elements, I believe, will assist in determining the age of tertiary deposits in Europe, more than any minute comparisons of species. Thus it is useless to seek in the Arctic regions for eocene floras, as we know them in our latitudes, for during the tertiary period, the climatic conditions of the earth did not permit their growth there. Arctic fossil floras of temperate and therefore to Heer miocene aspect, are in all probability of eocene age, and what has been recognised in them as a newer or miocene facies, is due to their having been first studied in Europe, in latitudes which only became fitted for them in miocene times.

When stratigraphical evidence is silent or inconclusive, this unexpected persistence and migration of plant-types or species throughout the tertiaries, should be remembered, and the degrees of latitude in which they are found should be well considered before conclusions are published respecting their age.

I need not here point out how completely this theory accords with that of the dispersion or migration of species from a northerly centre, so ably treated of by Asa Gray, Dawson, Dyer, Saporta, Hooker, and in fact by all who have pondered upon the subject, excepting Heer, for I hope to write a few words upon this at a future time. Before quitting it, for the present, Heer may as well learn that I am not alone in my opinions, for Prof. J. W. Dawson, of Montreal, considers with me that the reference of the beds in Greenland to miocene is not warranted by comparison with the tertiary plants of America.

"Immediately above these upper cretaceous beds we have the great lignite tertiary of the west—the Laramie group of recent American reports—abounding in fossil plants, at one time regarded as miocene, but now known to be lower eocene, though extending upward toward the miocene age. These beds, with their characteristic plants, have been traced into the British territory north of the 49th parallel, and it has been shown that their fossils are identical with those of the McKenzie River Valley, described by Heer as miocene, and probably also with those of Alaska, referred to the same age. Now this truly eocene flora of the temperate and northern parts of America has so many species in common with that called miocene in Greenland, that its identity can scarcely be doubted. These facts have led to scepticism as to the miocene age of the upper plant-bearing beds of Greenland, and more especially Mr. J. Starkie Gardner has ably argued, from comparison with the eocene flora of England and other considerations that they are really of that earlier date." [1]

Private correspondence has already informed me that others now share in these views.

Not content with withering my theories as to the eocene age of part of his miocene Arctic floras, Heer tilts against my explanation of the former higher temperatures which are known to have prevailed in our own and more northern latitudes. My explanation is, however, justified by our experience of what we conceive to be natural laws, and does not contradict that experience, and Heer has no theory to set up in its place.

The differences in the temperatures of the seas washing Arctic lands in the same latitudes are seen to alter the isothermal temperatures of their coasts to the extent of 27°; that is to say, the coasts which are refrigerated by the descending ice-laden currents are 27° colder than the shores of the North Cape, which are washed by an ascending current. With this fact and its causes palpably before us, we are justified in inferring that if the cold currents were shut off from these coasts, their temperature would rise by some 27°. The cold currents *were* shut off in the eocene time, for plants and animals passed freely between Europe and America, and therefore the temperature of the northern eocene lands may have been *from this cause* some 27° higher. But the Arctic eocene floras only required about 20° higher temperature, and the cause invoked is therefore more than sufficient.

Heer agrees with me that the higher temperature at the North Cape is due to warmer sea, and that continents extending far south also have their influence. He objects that Spitzbergen, being within the influence of the Gulf Stream, has a temperature of only 7° above the mean of its latitude. But then Spitzbergen is not shut in by the Gulf Stream, but only washed along one shore by it, and that after its current had been enfeebled and refrigerated to the last degree by the icy water it has to press through. Yet slight as the cause then is, it raises the isotherm of Spitzbergen 7°. He again objects that the closing of these outlets would stop the flow of the Gulf Stream. This, however, would not be the case completely. As long as any difference existed between the temperature to the north, and that under the tropics, a circulation would continue and would only cease when the whole Atlantic, north of the Equator, had reached a uniform heat. Not streams only, but the whole Atlantic from the Equator northwards, would be enormously warmed, and even parts of continents most remote from seas, would feel the influence.

This theory if true, Heer says, is at all events not original. In that case, so much the more likely to be true, but it is original to me.[2] It is true that very many theories have been put forward to account for former temperatures, and some of these have been based upon altered distributions of land and sea. But while some required change in the level of the sea, and others involved entirely novel continental areas, none have been supported by any kind of proof, either that the supposed changes had actually taken place, or were even competent to account for the former temperatures. The theory I have ventured to put forward is only absurd in its simplicity. The Atlantic may be likened to a great bath heated by the sun, from which we may shut off the cold taps either partially or entirely, from one or from both ends, thereby producing

[1] "The Genesis and Migrations of Plants," by J. W. Dawson. The *Princeton Review*, 1879, p. 282.
[2] NATURE, vol. xix. p. 123.

any known gradation of sea temperature. It not only accounts for the eocene heat when the land in the 70th and 80th parallels was upheaved by enormous volcanic action; the cooler miocene brought about when this action subsided, and permitted Arctic seas to again find egress; and the cold glacial period when both shores of the Atlantic were frozen by icy currents, as one shore is now; but by shutting off Antarctic currents it might have produced the hottest cretaceous times. Even the latter supposition is rendered likely by the past and present distribution of life, and such conditions doubtless did exist in remote times.

I am, however, speculating beyond the scope of my present paper, for, however the eocene climate was produced, the Arctic floras, I believe, flourished in it. Again I will close my paragraph with an extract from Dawson:[1] "But overlying this plant-bearing formation we have an oceanic limestone (the Niobrara) . . . . indicating that the land of the lower cretaceous was replaced by a vast Mediterranean Sea, filled with warm water from the equatorial currents, and not invaded by cold waters from the north. This is succeeded by thick upper cretaceous deposits. . . . these show that further subsidence or denudation in the north had opened a way for the Arctic currents, killing out the warm-water animals of the Niobrara group, and filling up the Mediterranean of that period."

J. STARKIE GARDNER

[1] The *Princeton Review*, 1879, p. 282

AN ENGLISH MICROSCOPE FOR THE USE OF STUDENTS OF MINERALOGY AND PETROLOGY

IT may interest those who are studying petrology to know that a new microscope, specially suited for mineralogical and petrological research, has recently been constructed by Mr. T. W. Watson, of Pall Mall.

For several years past students have frequently asked me to recommend some microscope to them which would answer their requirements, and, finding that none of the cheaper instruments manufactured in this country were supplied with concentrically-rotating stages, bearing divided circles, and that even the high-class instruments failed to fulfil all the requirements, it appeared that this want might be supplied at a moderate cost, if one of our instrument-makers could be induced to make a few trials.

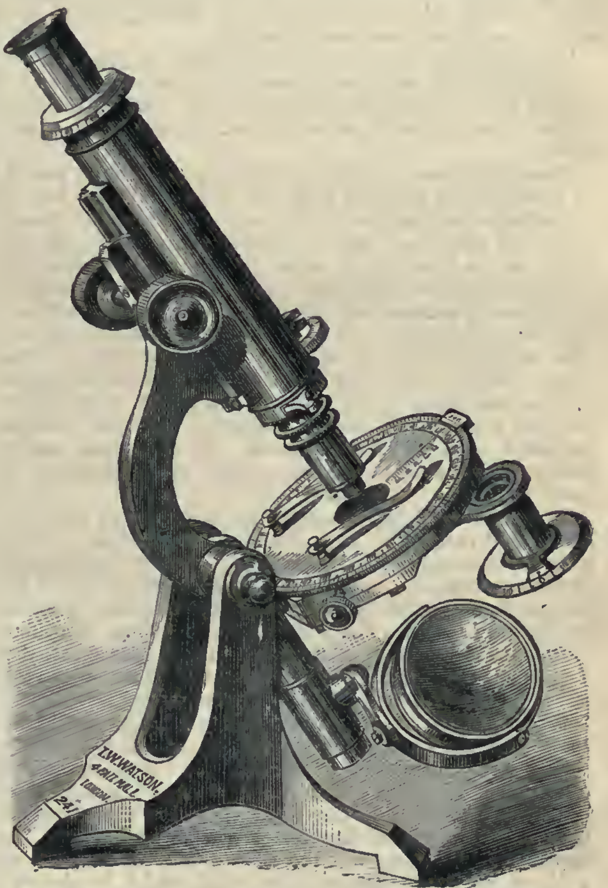
An examination of one of the microscopes devised by Prof. Rosenbusch and manufactured by Fuess, of Berlin, showed me that, although that instrument possessed many features of great merit, it also had certain defects which could be best overcome by adopting and modifying a good English model.

The great defects in most of the microscopes built on the continental patterns consist in their fixed vertical position, the smallness of their stages, and, very commonly, in the absence of any means of coarse adjustment, except by a sliding movement of the body or tube, which, if working stiffly, is very inconvenient, while, if sliding easily, is apt to be shifted by a very slight touch.

The microscope of Prof. Rosenbusch, apart from one or two of these defects, is a very admirable instrument, and presents various advantages over all other microscopes hitherto made.

The instrument, now manufactured by Mr. Watson, is in most respects quite equal in performance to Rosenbusch's microscope, so far as the mechanical appliances and adjustments are concerned, and is, I think, in point of convenience, decidedly superior to the latter instrument.

The foot is a brass casting of a pattern somewhat similas to that of Ross and other well-known makers. Upon this a gun-metal limb is supported on trunnions, which constitute the axis upon which the limb turns, so that the instrument can be inclined at any angle, or placed in a horizontal position for drawing. The right trunnion carries a clamp to fix the instrument at any angle. The lower portion of the limb bears the mirror, attached to a jointed arm. The upper part of the limb is bowed, or goose-necked, which renders it convenient as a handle, by which to lift the stand, without entailing any strain upon the working parts of the instrument. Above the curve it is ploughed out to receive the rack of the body or tube (on the pattern known as the "Jackson Model"), and the coarse adjustment is effected by a pinion turned by milled heads. The fine adjustment is of the usual kind, and is situated near the lower extremity of the tube. In the stand first made the milled head of the fine adjustment was divided for the measurement of the thickness of sections, but in future it is proposed to effect this object in a different manner by divisions engraved upon the limb and the sliding portion of the coarse adjustment.



The head of the tube or body carries a bevelled disk which is divided to 10° spaces. A corresponding disk with an index is attached to the bottom of the analyser-fitting, and rests directly upon the fixed divided disk; so that the analyser can be set in any required position, and any amount of revolution imparted to it can also be registered. The eye-piece, when inserted, is kept in a fixed position by a stud, which falls into a small slot. Crossed cobwebs are fixed within the eye-piece for the purpose of centring the instrument. A small plate of calc-spar, cut at right angles to the optical axis, is mounted in a little metal ring, which can be placed between the eye-glass and the analyser for stauroscopic examinations.

At the lower end of the microscope-tube a slot is cut to receive a Klein's quartz plate or a quarter-undulation plate, both of which are set in small brass mounts. When these are not in use the aperture can be closed by means of a revolving collar.

The thread which receives the objectives is of the gauge commonly used in this country, but an adapter can also be supplied which will carry the objectives of Hartnack and other continental opticians.

The stage is circular and capable of rotation, and it is divided on the margin to 360°. A vernier is attached to the front of the stage, giving readings to one minute. The edge of the stage is milled, and rotation is imparted by hand.

To insure concentric rotation with any powers used, two screws, carrying milled heads, are connected with the back of the stage. By the employment of these adjusting screws and the cobwebs in the eye-piece, a small object may readily be centred, so that it will revolve about a point central to the field afforded by any objective.

The object is held either by sliding clamps or by spring clips, and is moved about by hand. With a little practice this simple method of moving the object will be found to answer every purpose.

The polariser slides into a fitting which is fixed to an arm pivotted on the lower, movable surface of the stage, so that it can readily be displaced when ordinary transmitted illumination is required, and replaced with equal facility.

Two little lenses, affording a strongly-convergent pencil of light, are set in metal rings which drop into the top of the fitting which surrounds the polarising prism. When these are employed and the analyser is used, without lenses in the eye-piece (a separate fitting is supplied for this purpose), examinations of the rings and brushes, presented by sections of certain crystals, can be advantageously carried on, and a quarter-undulation plate can also be employed when needful. The lower end of the fitting which carries the polariser is surrounded by a divided disk, turning beneath a fixed index, so that any position of the prism can be recorded and the rotation imparted to it can be measured. Several other useful pieces of apparatus can be added to the stand at a moderate cost.

From the foregoing description it will be seen that this instrument is capable of performing the functions of an ordinary microscope, a polariscope, a stauroscope, and, to some extent, a goniometer. A spectroscope could be fitted to it if needful, as well as an apparatus for heating sections of crystals. For a few pounds separate binocular tubes can be supplied, to replace, in a few seconds, the single, but more generally useful, tube. The objectives of any maker can be used with the instrument.

Having carefully tested one of these microscopes I can speak most favourably of its performance. It is strongly constructed, convenient to handle, and the adjustments work very smoothly. The price of this stand is also remarkably moderate when compared with that of many microscope-stands of far less universal application. It appears to me well qualified to answer the requirements of students of mineralogy and petrology, and it is also applicable to other studies for which microscopes are commonly required.

Mr. Watson has taken especial pains to turn out a sound and serviceable instrument, and, after long experience of microscopes, I can confidently say that I have never seen one better suited for the work for which it is designed.

FRANK RUTLEY

STELLAR MAGNITUDES

A REQUEST TO ASTRONOMERS

THE scales adopted by different observers in their estimates of stellar magnitudes differ considerably from each other, as is well known. As regards the brighter stars, these differences, indeed, are comparatively unimportant; but they become larger and more perplexing when the objects observed are faint. Variations of three or four magnitudes may be expected between the estimates made of the brightness of minute companions seen near a brilliant star. It is needless to point out the inconvenience of this state of affairs, which at times nearly deprives the estimated magnitudes, found in catalogues, of their meaning, and consequently of their value.

In the hope of providing a partial remedy for this defect, a series of photometric observations of stars of various magnitudes, situated near the north pole, has been undertaken at the Harvard College Observatory. The region has been selected as one which may always be conveniently observed in the northern hemisphere, so that the brightness of a star observed in another part of the sky can readily be compared by estimate with any standard polar stars, the relative brightness of which may have been determined by photometric measurements.

The table and chart given below are designed to serve as guides in finding the stars which are, as has been said, in course of phonometric measurement at the Harvard College Observatory. The stars given in the table are arranged approximately in the order of their brightness, the first being α Ursæ Minoris, which is taken in all cases as the standard of comparison, and the next three, δ Ursæ Minoris, 51 Cephei, and λ Ursæ Minoris. The chart is a copy of a sketch showing the approximate relative position of ten faint stars very near the pole, which are denoted by the italic letters *a, b, c, d, e, f, g, h, k, l.* The places

DM. ° ′	α 1880. h. m.	δ 1880. ° ′
88 8	1 14	88 40
86 269	18 11	86 37
87 51	6 44	87 14
88 112	19 44	88 57
88 4	0 51	88 23
88 9	2 3	88 36
89 3	2 28	89 36
89 35	17 50	89 48
89 37	19 28	89 54
89 1	0 19	89 45
89 26	13 23	89 49

of the pole for 1855, 1880, and 1900, and of five stars from the Durchmusterung, four of which occur in the table, are also indicated upon the chart, to facilitate the identification of the faint stars. The objects called *c* and *e* are nearly in the prolongation of the line through DM. 89° 37′ and *b*. Between these last, and more nearly in the same line than it appears to be in the chart, lies the star *a*.

The value and interest of the photometric results to be obtained at the Harvard College Observatory may be greatly increased by the co-operation of astronomers elsewhere. All who are desirous of improving the present

system of comparing the brightness of stars, are therefore requested to make estimates of the magnitude of as many as may be convenient of the stars above mentioned. It is desirable that the estimate should be made, for each star which may be observed, on five different nights, and that each estimate should be, if possible, entirely independent of those previously made. It will add to the value of the work if, on every occasion when the fainter stars are looked for, a record is made of such of them as can then be seen, even if no estimate of their magnitude is attempted.

Observers are also requested to note the approximate places of any stars not represented upon the chart, but within five minutes of the place of the pole at any time between 1880 and 1900. The boundary of this region is represented on the chart by a dotted line. The stars not shown within it have been omitted as unnecessary for the purpose of finding the others, and several of these omitted stars are inconveniently faint for photometric observations; but records of their visibility at any time and place will be valuable as evidence of the state of the atmosphere and character of the instrument employed in the observations.

All astronomers who may be induced by this request to make any observations of the kind just described will confer a favour upon the Harvard College Observatory by sending to it a copy of their records, accompanied by a statement of any modification of the proposed method of observation which they may have adopted, as well as any additional details which may appear desirable, with regard to the instruments employed, &c. Unless the contrary is requested, the results will be published with the photometric measurements obtained at the Harvard College Observatory; and a copy of the publication will be sent to each observer who has co-operated in the work.

It is hoped that a large number of those astronomers whose experience has been sufficient to establish a definite scale for their estimates of stellar magnitude will consent to take part in the proposed observations, in order that the published series of observations may be complete enough to be of general utility.

EDWARD C. PICKERING
Director of the Harvard College Observatory

GEOGRAPHICAL NOTES

AT the meeting of the Royal Geographical Society on Monday evening it was announced that the gold medals had that day been awarded to Col. Nicholas Prejevalsky for the great additions he has made to our knowledge of Central and Eastern High Asia by his successive expeditions into the unexplored parts of the great plateau of Mongolia and the lofty deserts of Western Thibet, and for the admirable way in which he has described the regions traversed by him in the published narratives of his journeys; and to Capt. W. J. Gill, R.E., for excellent geographical work performed during two journeys of exploration, voluntarily undertaken, along the northern frontier of Persia in 1873, and over previously untravelled ground in China and Thibet, in 1877; also for the elaborate memoir and route maps contributed to the forthcoming volume of the Society's *Journal*. A paper was afterwards read by the Rev. James McCarthy, of the China Inland Mission, descriptive of the journey which he made, mostly on foot, in 1877, across China, from Chinkiang, on the Yangtsze-Kiang, to Bhamô, in Burmah. The leading features of this journey have been fully described in NATURE. The most noteworthy incident of the evening was a speech, delivered in his native language by the Marquis Tsêng, Chinese Minister to England and France, expressive of the pleasure which he felt at Mr. McCarthy's acknowledgment of the uniformly courteous treatment he experienced during his long journey.

AT the next meeting of the Geographical Society on May 12, the second of the course of scientific lectures of the present session will be delivered by Prof. G. Rolleston, of Oxford, on the "Modifications of the External Aspects of Organic Nature produced by Man's Interference."

NEWS has arrived by the last mail from Zanzibar that Mr. H. M. Stanley is busily occupied in engaging porters for a journey into the interior of Africa, but that he preserves the utmost secrecy as to his intended movements. A rumour is current amongst the porters that their journey is to commence from the west coast; if this be the case, Mr. Stanley must have introduced a radical change into the original plans of the Belgian section of the International African Association, for whom he is believed to be acting. That, accidents apart, he will be more successful than the unfortunate leaders of the first Belgian expedition few will be so rash as to doubt, and he is sure to have good and sufficient reasons for the course he is adopting.

DURING the past few days there has been a considerable exodus of missionary explorers. Dr. James Stewart, the well-known head of the Livingstonia station, has returned to his post, and will soon be adding more to our knowledge of the shores of Lake Nyassa. Dr. Joseph Mullens, of the London Missionary Society, who has already done good service to geography in Madagascar, has started for Ujiji, on Lake Tanganyika, and before returning home he will probably make his way down to the north end of Lake Nyassa, thus filling up an important blank in our knowledge of the lake region. Lastly, the Rev. T. J. Comber, of the Baptist Missionary Society, has returned to Western Africa to found a station at San Salvador, and eventually to conduct a missionary expedition to the upper waters of the River Congo.

THE general report of last year's operations of the Marine Survey of India, under Commander A. Dundas Taylor, late I.N., has just reached this country. During that period two parties carried out the following surveys: Ratuagiri, including Mirya and Kalhadevi Bays; Viziadurg, including Rajapur and Ambol Ghur Bays; Paumben Pass (between Ceylon and the mainland) and its approaches; Beypore, Calicut, and Cochin. The natural history investigations of the season have been confined to an examination of the fauna inhabiting the shores in the vicinities of Ratnagiri and Viziadurg, and to the collection and preservation of the various ornithological specimens procured. The area examined includes the tract of country lying between the above places from the sea to the chain of hills known as the Western Ghâts. The examination of the sea-bottom with the dredge was impracticable, owing to the want of a vessel; this want, however, has since been supplied, as was recorded in NATURE, vol. xix. p. 298, and no doubt interesting results will be obtained during the present season. Captain Taylor's report is accompanied by a useful map showing the surveys completed by his officers, together with the sheets published or in course of publication, 1877-8.

THE second session of the Congress of Commercial Geography, inaugurated at Paris last year, will be held at Brussels in September, under the presidency of M. Bamps, and arrangements for the meeting have already been commenced.

NEWS has been received from Queensland that the remains of the two Prouts, well-known explorers, have at length been discovered, so that the question of their fate is now finally set at rest.

AT the last meeting of the Société de Géographie Commerciale at Paris Dr. Harmand gave some account of his observations in the Laos country of the Indo-Chinese peninsula. He stated that though elephants were common there, ivory was dearer than in Paris, and that the same remark applied to rhinoceros-horn. There are mines of lead, iron, and copper in the country, and probably gold

will be found. The chief productions are indigo, lacquer, saffron, rice, cotton, &c., but the industry of the country is in a very undeveloped state.

A NEW project for the creation of an inland sea has been advanced and advocated by General Fremont, at present Governor of Arizona. The removal of a barrier ridge, he affirms, would admit the waters of the Gulf of California into an ancient basin, and would create a navigable inland sea 200 miles long, 50 miles broad, and 300 feet deep. This piece of engineering, which is very like Roudaire's Algerian inland sea project, he claims, would convert what is now a desert region into a commercial highway, and would greatly improve the climate of Southern Arizona and California.

AT last week's meeting of the Paris Academy M. de Lesseps announced that in a letter of April 15, Capt. Roudaire states that the sounding operations were being pursued with vigour and success, and that so far they justified the expectation of being able to create an interior Algerian Sea.

AN exploring expedition to New Guinea is being organised at Wellington, New Zealand, on a large scale.

L'Exploration states that a new African expedition is being organised at Lisbon, under the direction of Capt. Paiva d'Andrada. Its object is the exploration of the Zambezi and the foundation of commercial and agricultural colonies in the territories of Fete and Zoumbo.

IN the *Verhandlungen* of the Berlin Geographical Society, Nos. 2 and 3, is a suggestive paper by Dr. Güssfeldt on the Ice-Conditions of High Mountains. No. 80 of the *Zeitschrift* contains a paper of much originality, on the causes which have conduced to the formation of the surface of Norway, by Prof. Kjerulf.

Globus is publishing a valuable series of articles on the Red River of the North, from the French of M. de Lamothe, and the Hundu Kush Alps by Herr Emil Schlagentweit.

NOTES

THE Annual London Meeting of the Iron and Steel Institute will be held on Wednesday, Thursday, and Friday, May 7, 8, and 9, at the Institution of Civil Engineers, 25, Great George Street, Westminster. The following programme of proceedings has been arranged :—On Wednesday the retiring President (Dr. C. W. Siemens, F.R.S.), will take the chair at 10.30 A.M., and the President-Elect (Mr. Edward Williams) will deliver his inaugural address. The Bessemer Medal for 1879 will be presented to Mr. Peter Cooper, of New York, "the father of the American iron trade." The adjourned discussion on the paper read at Paris by Mr. Daniel Adamson, C.E., of Manchester, on "The Mechanical Properties of Iron and Mild Steel," will be resumed, and Mr. Adamson will present a supplementary paper. On the following days the following papers will be read and discussed :—"On the Use of Steel in Naval Construction," by Mr. Nathaniel Barnaby, C.B., H.M.'s Chief Constructor. "On the Use of Steel in the Construction of Bridges," by Mr. H. N. Maynard. "On the Elimination of Phosphorus in the Bessemer Converter," by Mr. Sydney G. Thomas, F.C.S., and Mr. Percy C. Gilchrist, A.R.S.M., F.C.S. "On the Removal of Phosphorus and Sulphur during the Bessemer and Siemens-Martin Processes of Steel Manufacture," by Mr. G. J. Snelus, F.C.S., &c. "On a New Volumetric Method of Determining Manganese in Manganiferous Iron Ores, Spiegeleisen, Steel, &c.," by Mr. John Pattinson, F.I.C., Newcastle-on-Tyne. "On a Ready Means of Moulding Lime, and making Lime or Basic Bricks and Linings for Furnace Converters, &c.," by Mr. Edward Riley, F.C.S., F.I.C., &c. "On a Practical Combination of the Bessemer and Puddling Processes," by Mr. Edwin Pettitt, Cheltenham. "On the Results of Working the Godfrey-Howson Furnaces at the Works of Tamaris, Gard, France," by M. Escalle. "On the Chemistry of Puddling," by Mr. H. Louis, A.R.S.M., Londonderry, Nova Scotia. "On a New Process for Protecting Iron and Steel against Rust," by Prof. Barff.

THE Rev. W. H. Dallinger, F.R.S., has been appointed Rede Lecturer at Cambridge this year.

AMONG those on whom the degree of LL.D. has been conferred by the Glasgow University is Dr. C. W. Siemens, Prof. Hull, director of the Irish Geological Survey, and Prof. Dickson, newly elected to the Edinburgh Chair of Botany.

THE death is announced of Dr. Charles Murchison, F.R.S.

MADEMOISELLE ADELAÏDE MONTGOLFIER, a daughter of the inventor of balloons, is still alive, aged eighty-nine years. She is possessed of a large fortune, and presented the Museum of the Aëronautical Academy with a copy of the large medal executed by Houdon, and representing her father and uncle, who was associated with him in the invention of balloons. This medal was executed to commemorate that event. A movement will be got up in France for celebrating the centenary of that memorable event, which took place in June, 1783, in the vicinity of Lyons.

THE annual conference on National Water Supply, Sewage, and Health, will be held in the rooms of the Society of Arts, on Thursday and Friday, May 15 and 16, 1879. There will be an Exhibition of Mechanical and Chemical Apparatus in connection with Water Supply, Treatment of Sewage, and Health. Papers on any of above heads are requested. The object of the conference is to discuss existing information in connection with the results of any systems already adopted in various localities, referring to the subjects of National Water Supply, Sewage, and Health; to elicit further information thereon; and gather and publish, for the benefit of the public generally, the experience gained. The introduction and discussion of untried schemes will, therefore, not be permitted. The papers accepted for the conference will be printed and circulated at the meetings.

PROF. TYNDALL has been instructing the Select Committee appointed to inquire into the subject of electric lighting. He gave a brief sketch of the history of electricity and of its application to lighting purposes, illustrating his evidence by several interesting experiments. Seeing what had been done by Mr. Edison, he believed that many of the existing difficulties would be removed; for public illumination he was afraid platinum would be too expensive. Dr. Siemens has also been giving important evidence on the subject.

WE are glad to see that Dr. Brehm, the well-known naturalist, accompanies the Crown Prince of Austria in his tour through Spain.

WE learn from *Science News* that the Brazilian Government has appointed Mr. Orville A. Derby as geologist to the National Museum at Rio de Janeiro, to succeed the late Prof. Hartt, whose assistant Mr. Derby had been for a number of years. Next to Prof. Hartt, Mr. Derby was probably best acquainted with the geological structure of Brazil, and he is, therefore, the one most fitted to carry on the work. He accompanied Prof. Hartt, as an assistant, on both of his Amazonian trips, in 1870 and 1871, and largely shared in the honours arising from the discoveries made during those years, by which a firm foundation was laid for the complete geological exploration of the great valley.

THE following arrangements have been made for the meetings of the Society of Arts after Easter :—At the ordinary meetings on Wednesday evenings, at eight o'clock: May 14—"The Automatic Hydraulic Brake," by E. D. Barker; May 21—"Edison's New Telephone," by Conrad W. Cooke. In the African Section, on Tuesday evenings at eight o'clock: May 27—"The Contact of Civilisation and Barbarism in Africa, Past

and Present," by Edward Hutchinson. In the Chemical Section, on Thursday evenings, at eight o'clock: May 8 and 15—"The History of Alizarine and Allied Colouring Matters, and their Production from Coal Tar," by W. H. Perkin, F.R.S. In the Indian Section, on Friday evenings, at eight o'clock: May 2—"The Wild Silks of India, especially Tussah," by Thomas Wardle; May 23—"The Harbour of Kurrachee," by W. J. Price.

A SPECIMEN of the electro-magnetic engine invented by M. Marcel Deprez is employed by the Academy of Aëronautical Ascensions, 50, rue Rodier, Paris, for working a sewing-machine which is used for the construction of a balloon called *L'Électricité*. The weight of the motor is only 4 kilogrammes, and four Bunsen elements of ordinary size are sufficient to give to the needle the required velocity.

FROM to-day postal cards will be sold in Paris at the price of 50 centimes each, for the transmission of messages by the pneumatic tube which connects the several telegraphic stations in the French metropolis.

IN a memoir presented to the Academy of Sciences and Literature of Lyons, we learn from the *British Medical Journal*, Dr. Henry H. Dor, a well-known oculist, contests the view held by Mr. Gladstone, and by Geiger and Magnus of Boston, that our ancestors were colour-blind, a view deduced from their writings and from the different names which they have given to colours. Dr. Dor endeavours to demonstrate that now, as in the time of Homer, poets insist too little upon the indications of the colours, but much more upon their luminous intensity. Moreover, Dr. Dor says that persons who do not possess any knowledge of physics find much difficulty in distinguishing the colours of the rainbow, and only see in it three or four colours, in place of the seven classical colours of its composition. Further, it results even from the very study of the Assyrian and Egyptian monuments, that those nations had not only perceived, but imitated, the greater part of the colours of which we are at present cognisant.

THE second annual meeting of the Midland Union of Natural History Societies will be held in the council chamber of the Town Hall, Leicester, on Tuesday, May 20, at half-past three o'clock. The business of the meeting will be to receive the report of the Council and the treasurer's accounts; to fix the place of the next annual meeting in 1880; to consider any suggestions that members may offer; to discuss the work of the Union during the coming year; and to transact all necessary business. The President will open the business with an address. A *conversazione* will be held in the Leicester Town Museum (entrance in Hastings Street) on Tuesday evening, May 20, the arrangements for which are under the direction of the Leicester Literary and Philosophical Society. There will be an exhibition of objects of general scientific interest, microscopy, the various departments of natural history, archæology, and art. On Wednesday, May 21, there will be an excursion to Charnwood Forest.

FROM the *Gardeners' Chronicle* we learn that an Agricultural and Horticultural Society has been founded at Mentone, many of the members being English residents.

THE *Electrician* of April 26 contains a long letter from Prof. Clerk Maxwell on the correct definition of "Potential."

AMONG Mr. Murray's list of announcements is "The River of Golden Sands," a narrative of a journey through China to Burmah, by Capt. William Gill, R.E., and "A History of Ancient Geography," by E. H. Bunbury.

THE *American Naturalist* for April contains a curious paper, by Mr. Xenos Clarke, on "Animal Music, its Nature and Origin." Mr. W. O. Crosby has a paper on "Native Bitumens and the Pitch Lake of Trinidad," and Mr. W. H. Holmes on a Deposit of Obsidian in the Yellowstone Park.

GRAVITATION experiments in liquids have recently been made by Herr Schröttner in Vienna, with a view to determining viscosity (as previously proposed by Pisati and De Heen). He took as basis a formula of Stokes for the resistance of a ball moved in a straight line in a liquid, and sought to determine the coefficients of friction in absolute measure. The practicability of the method was proved in a very viscous mixture of black pitch and beech-tar, and in concentrated glycerine. For the latter, higher values were obtained than by the transpiration-experiments carried on at the same time. From the author's experiments with glycerine, as also from Schieck's gravitation experiments with water, it appeared that the coefficients of friction were considerably greater whenever the velocities of fall exceeded a certain amount. For liquids with little viscosity, as water, small velocities of fall, such as met the conditions of experiment, could only be obtained by giving the balls a surplus weight of a few hundredths of a milligramme over the displaced mass of liquid, in case experiments were not made with very large balls and very considerable quantities of liquid.

ROMAN remains have just been discovered at Oberbreisig, a village near the Rhine, a few miles to the south of Bonn. A rectangular building of unquestionably Roman origin has been laid bare, the purpose of which, however, is very doubtful. The excavations leading to this discovery are in connection with others of greater extent which are being made in the neighbourhood, and which are principally directed to the investigation of a Roman villa near Waldorf and a Roman road leading to Sinzig.

IN a recent memoir communicated to the Belgian Academy, M. Lagrange offers some novel views on the formation of bodies in the universe. He supposes that before any expenditure of work the quantity of heat of the universe was *nil*, and that the temperature was gradually raised above absolute zero at the expense of work done by attraction. Hence the formation of solid bodies must have preceded that of liquids and gases. Through the gradual condensation of matter and consequent enormous development of heat, the earth would attain, at least in the parts near the surface, the state of fluidity necessary to explanation of its form and geological characters. As the temperature gradually rose with gradual agglomeration of matter, a very dense atmosphere would form, with pressure diminishing outwards, and in a more advanced phase, the temperature of this, after reaching a maximum, would gradually diminish, causing liquefaction or solidification of certain matters at first vaporous, while other solid bodies might remain suspended in the atmosphere. M. van der Mensbrugghe commends the author's views as original and worthy of the attention of *savants*, but, with M. Folie, he regards the initial absolute zero as inadmissible. In reply to objections by M. Folie, the author promises shortly to defend this hypothesis:—Space is occupied by two substances; one, attractive, which is matter properly so-called, or material atoms; the other, repulsive, which occupies the inter-atomic space, and from which results, between any two atoms, a variable repulsion exercised at the surface of the latter.

WE have received No. 11 (March, 1879) of the *Bulletin* of the Brooklyn Entomological Society, of the existence of which publication we were not previously aware. It consists of a half-sheet 8vo, with one plate, illustrating a paper by C. F. Gissler on Coleopterous larvæ of the family *Tenebrionidæ*, which appears to be carefully worked out and likely to prove of value, and the figures (chiefly concerning the pygidia and antennæ) seem to be well drawn. The other papers are on the genus *Colias*, *Samia cynthia*, and on some species of *Thecla*. The number of

American serials exclusively devoted to entomology is constantly increasing.

A SLIGHT earthquake was felt between 9.15 and 9.30 P.M., April 24, at Sigmaringen. The direction was not observed. The following particulars have reached the *Times* of the earthquake which occurred in Persia on March 22, at 3.42 A.M. (London time, 12.37 A.M.). It lasted 12s., was felt at Tauris and east as far as Zendjan; no damage was caused in Tauris, but in the vicinity of Mianeh, where the shocks continued with more or less vigour up to April 2, great damage and loss of life have occurred. An official report, prepared for the Persian Government by the Persian Telegraph authorities at Mianeh gives the damage, as far as is at present known, as follows:—21 villages totally destroyed, 54 greatly damaged, 922 persons killed, together with 2,660 sheep, 1,125 oxen, 124 horses, and 55 camels. The centre of the disturbances was the mountain of Bousgonche.

WE learn from the *Colonies and India* that an American explorer has recently discovered in the little-known district of Yucatan, bordering on British Honduras, a valuable insect, possessing properties which ought to make it a rival of the cochineal and shellac-producing insects. This is the *neen*, or *niin*, a species of *Coccus*, which feeds on the mango tree and similar plants, and exists in enormous quantities in Central America. It is of considerable size, of a yellowish brown colour, and emits a peculiar oily odour, containing as it does, a large quantity of fatty oil, or rather grease. This grease is used by the natives for various purposes, being highly prized as a medicinal oil for external application, and it is also employed for mixing paints. It can be made to change its condition very considerably by different processes. When exposed to great heat, the lighter oils evaporate, leaving a tough flexible mass, resembling half-softened wax, but unaffected by heat or cold, which may be used as a lacquer or varnish. When burnt, this material produces a thick semi-fluid mass, somewhat resembling a solution of india-rubber, which after a few days becomes hard and solid. As a cement this substance will be invaluable, and it might also be used for waterproofing purposes.

WITHIN a few days the scientific committee for the organisation of the Paris Exhibition of Applied Sciences will hold an important meeting. The exhibition will be open from July to November.

SEVERAL of the Conseils Généraux of the surrounding departments have voted funds for the erection of an observatory on the top of Mont Ventoux, in Vaucluse. It will be the third high meteorological station in France, and very likely not the last. M. Ferry, the Minister of Public Instruction, is favourable to the erection.

"THE Silk-Worm, being a brief Manual of Instruction for the Production of Silk," is the title of a pamphlet by Mr. C. V. Riley, professor of the U.S. Department of Agriculture. Silk-worm rearing seems likely to become an important industry in some parts of the United States.

THE March number of the *Journal* of the Statistical Society contains the concluding part, upwards of 180 pages, of Mr. C. Walford's elaborate and valuable paper on the Famines of the World. The whole paper, we believe, will be published separately.

MESSRS. HEYWOOD, of Manchester, have just published the tenth series of Science Lectures for the People delivered in that city. The volume, which can be had for a few pence, contains nine lectures by some of the most eminent men of science of the day. Huxley lectures on William Harvey, Roscoe on the Sun, Flower on the Tasmanians, Williamson on Insectivorous Plants, Barrett on Edison and his Inventions, Dawkins on Our Earliest Ancestors in Britain, Abel on the Modern History of Gunpowder, Dallinger on the Minutest Forms of Life, and Romanes on Animal Intelligence. Several of the lectures are illustrated.

MR. RICHARD RATHBUN has reprinted from the *Proceedings* of the Boston Society of Natural History, a pamphlet of 25 pages on the Devonian brachiopoda of the Province of Para, Brazil. The list is a long one, and many species are described for the first time.

IT will be difficult to surpass or even equal our American friends in the illustrated scientific works which they have begun to publish in such quantity. We have had occasion to mention more than one work of this class recently, and now we receive the first part of "Characeæ Americanæ," illustrated, described and published by Dr. T. F. Allen, of New York. The particular specimen described, and illustrated by an exquisitely coloured plate, is *Chara gymnopus*, A. Br., var. *elegans*, A. Br.

WE have on our table the following works:—"Our New Protectorate," 2 vols., J. C. McCoan (Chapman and Hall); Karl von Gebler's "Galileo Galilei," translated by M. Sturge (Kegan Paul and Co.); "The Encyclopædia Britannica," vol. ix. (A. and C. Black); "Geography" (School Books for South Africa, No. 1), Dr. John Shaw (W. Collins); "Elements of Natural Philosophy," Part i., Second Edition, Thomson and Tait (Printed at Cambridge University Press); "Chemistry of Common Life," J. F. W. Johnson and A. H. Church (Blackwood and Co.); "Shadows of the Coming Truth" (Elliot Stock); "Caves of South Devon and their Teachings," J. E. Howard (Hardwicke and Bogue); "Scientific Results of the Second Yarkand Mission;" 6 Plates, from the Notes of Ferdinand Stoliczka (Quaritch); "End-on Illumination in Private Spectroscopy," Piazzi Smyth (Neil and Son, Edinburgh); C. Peschel's "Geschichte der Erdkunde," Parts i. and ii., Edited by Prof. Dr. Sophus Ruge (R. Oldenburgh, München); "Pre-Historic Times," fourth edition, Sir John Lubbock, Bart. (F. Norgate); "Dictionary for Architects," No. 1, W. J. Christy (Griffith and Farren); "Reduction of Greenwich Meteorological Observations" (Spottiswoode); "The Flowers of the Sky," R. A. Proctor (Strahan); "On Certain Effects of Starvation on Vegetable and Animal Tissues" (D. D. Cunningham, Government Printer, Calcutta); "The Microscopic Organisms found in the Blood of Man and Animals" (Government Printer, Calcutta); "Rambles in North-Western America," J. M. Murphy (Chapman and Hall); "Atlas of Histology, Parts 1 and 2, E. Klein and N. Smith (Smith Hall); "How to learn Danish," E. C. Otté (Trübner and Co.); "Key to How to Learn Danish," E. C Otté (Trübner and Co.); "Anatomy and Physiology of Man," G. G. P. Bale (Remington and Co.); "On Artificial Manures," by M. Georges Ville, translated and edited by William Crookes (Longmans); "Agricultural Ants of Texas," H. C. McCook (Trübner); "De la Ligue Contre les Vivisections, ou la Nouvelle Croisade," Par un Anglais (Ernest Leroux); "L'Eclairage Electrique," Le Comte Th. du Moncel (Hachette); "Contributions to the Anatomy of the Central Nervous System of Vertebrate Animals," Alfred Saunders; "Infection—Diseases in the Army," Prof. R. Virchow (H. K. Lewis); "Recherches sur l'Électricité," Gaston Planté (Paris, A. Fournan); "On the Daily Inequality of the Barometer" (W. W. Rundell); "Freedom in Science and Teaching," Ernst Haeckel (Kegan Paul and Co.).

THE additions to the Zoological Society's Gardens during the past week include a Black-handed Spider Monkey (*Ateles melanochir*) from Central America, presented by Mr. D. R. Comyn; two Prairie Marmots (*Cynomys ludovicianus*) from North America, presented by Mr. W. G. Marshall; a Guilding's Amazon (*Chrysotis guildingi*) from St. Vincent, West Indies, presented by Mr. G. Dundas, C.M.Z.S.; a Cuvier's Podargus (*Podargus cuvieri*) from Australia, presented by Mr. R. S. C. Baber; a Lesser Long-eared Bat (*Plecotus brevimanus*), British Isles, presented by Mr. J. Ward; a three-toed Amphiuma (*Amphiuma means*) from North America, presented by Mr. A. C. Cole; a Bonnet Monkey (*Macacus radiatus*) from India, an Egyptian Cat (*Felis chaus*) from North Africa, a Common Ass (*Asinus vulgaris*) from Persia, a Grey-headed Porphyris (*Porphyris poliocephalus*) from South Asia, a Puff Adder (*Vipera arietans*) from the Cape of Good Hope, deposited.

RECENT CONTRIBUTIONS TO THE HISTORY OF DETONATING AGENTS[1]

AMONG the many explosive preparations which have during the last thirty years been proposed as substitutes for gunpowder, on account of greater violence and other special merits claimed for them, not one has yet competed with it successfully as a propelling agent, nor even as a safe and sufficiently reliable explosive agent for use in shells; for industrial applications and for very important military or naval uses, dependent upon the destructive effects of explosives, it has had, however, to give place, to a very important extent, and in some instances altogether, to preparations of gun-cotton and nitro-glycerine.

But there appeared little prospect that either gun-cotton or nitro-glycerine, whether used in their most simple condition or in the forms of various preparations, would assume positions of practical importance as explosive agents of reliable, and therefore uniformly efficient, character, until the system of developing their explosive force through the agency of a detonation, instead of through the simple agency of heat, was elaborated.

Before the first step in this important advance in the application of explosive agents was made by Alfred Nobel, about twelve years ago, the very variable behaviour of such substances as gun-cotton and nitro-glycerine, when exposed to the heat necessary for their ignition under comparatively slight modifications of attendant conditions (*e.g.* as regards the completeness and strength of confinement or the position of the source of heat with reference to the main mass of the material to be exploded) rendered them uncertain in their action, and at any rate, only applicable under circumstances which confined their usefulness within narrow limits. The employment by Nobel of an initiative detonation, produced by the ignition of small quantities of mercuric fulminate or other powerful detonating substances, strongly confined, for developing the violent explosion, or detonation, of nitro-glycerine, opened a new field for the study of explosive substances, and the first practical fruit was the successful application of plastic preparations of nitro-glycerine and of compact forms of compressed gun-cotton, with simplicity and certainty, to the production of destructive effects much more considerable than could be accomplished through the agency of much larger amounts of gunpowder, applied under the most favourable conditions. Whereas very strong confinement has been essential for the complete explosion of these substances, so long as the only known means of bringing about their explosion consisted simply of the application of fire or sufficient heat, no confinement whatever is needed for the development, with certainty, of a decidedly more violent explosive action than they are capable of exerting when thus applied, if they are detonated by submitting some portion of the mass to the blow or concussion developed by a sharp detonation, such as is produced by the ignition of a small quantity of strongly confined mercuric fulminate.

The conditions essential to the development of detonation in masses of nitro-glycerine and gun-cotton, or preparations of them, and the relations to and behaviour towards each other of these and other explosive bodies, in their character or functions as detonating agents, have been made the subject of study by the lecturer during the last ten years, and some of the earlier results published by him in connection with this subject also led to the pursuit of experimental inquiries of analogous character by Champion and Pellet and others.

Some of the chief results attained by Mr. Abel's experiments may be briefly summarized.

It was found that the susceptibility to detonation, as distinguished from explosion, through the agency of an initiative detonation, is not confined to gun-cotton, nitro-glycerine, and preparations containing those substances, but that it is shared, though in very different degrees, by all explosive compounds and mixtures.

It was demonstrated that the detonation of nitro-glycerine and other bodies, through the agency of an initiative detonation, is not ascribable simply to the direct operation of the heat developed by the chemical changes of the charge of detonating material, and that the remarkable property possessed by the sudden explosion of small quantities of certain bodies (the mercuric and silver fulminates) to accomplish the detonation of nitro-glycerine and gun-cotton, is accounted for satisfactorily by the mechanical force thus suddenly brought to bear upon some part of the mass operated upon. Most generally, therefore, the degree of facility with which the detonation of a substance will develop similar change in a neighbouring explosive substance, may be regarded as proportionate to the amount of force developed *within the shortest period of time* by that detonation, the latter being in fact analogous in its operation to that of a blow from a hammer or of the impact of a projectile.

Thus, explosive substances which are inferior to mercuric fulminate in the suddenness, and the consequent momentary violence of their detonation, cannot be relied upon to effect the detonation of gun-cotton, even when used in comparatively considerable quantities. Percussion cap composition, for example, which is a mixture of fulminate with potassium chlorate, and is therefore much less rapid in its action than the pure fulminate, must be used in comparatively large quantities to accomplish the detonation of gun-cotton.

The essential difference between an explosion and what we now distinguish as a detonation lies in the comparative suddenness of the transformation of the solid or liquid explosive substance into gas and vapour.

The gradual nature of the explosion of gunpowder is illustrated, in its extreme, by burning a train of powder in open air; the rapidity and consequent violence of the explosion is increased in proportion to the degree of confinement of the exploding charge, or to the resistance opposed to the escape or expansion of the gases generated upon the first ignition of the confined substance.

In the case of a very much more sensitive and rapidly explosive substance than gunpowder, such as mercuric fulminate, the increase in the rapidity of its transformation, by strong confinement, is so great that the explosion assumes the character of a detonation in regard to suddenness and consequent destructive effect. A still more sensitive and rapidly explosive material (such as the silver fulminate and iodide of nitrogen) produces when exploded in open air effects akin to those of detonation; yet even with these bodies, confinement operates in increasing the rapidity of the explosive to suddenness, and consequently in developing a more purely detonative action.

Detonation, developed in some portion of a mass, is transmitted with a velocity approaching instantaneousness throughout any quantity, and even if the material is laid out in the open air in long trains composed of small masses. The velocity with which detonation travels along trains thirty or forty feet in length, composed of distinct masses of gun-cotton and of dynamite, has been found to range from 17,000 to 24,000 feet per second. Even when trains of these explosive agents were laid out with intervening spaces of half an inch between the individual masses composing the trains, detonation was still transmitted along the separated masses with great though diminished velocity.

The suddenness with which detonation takes place has been applied as a very simple means of breaking up shells into small fragments and scattering these with considerable violence, with employment of very small charges of explosive agent. Thus by filling a 16-pr. common shell completely with water and inserting a charge of ½ oz. of gun-cotton fitted to a detonating fuze, the shell being thoroughly closed by means of a screw plug, the force developed by the detonation of the small charge of gun-

[1] Weekly Evening Lecture at the Royal Institution, Friday, March 21, 1879. By Professor Abel, C.B., F.R.S. Revised by the Author.

cotton is transmitted instantaneously in all directions by the water, and the shell is thus broken up into a number of fragments averaging fourteen times the number produced by bursting a shell of the same size by means of the full amount of powder which it will contain (13 oz.). Employing 1 oz. of powder, in place of ½ oz. of gun-cotton, in the shell filled with water, the comparatively very gradual explosion of the powder charge is rendered evident by the result; the shell being broken up into less than twenty fragments by the shock produced by the first ignition of the charge, transmitted by the water. In this case the shell is broken up by the minimum amount of force necessary for the purpose, before the explosive force of the powder charge is properly developed. Extensive comparative experiments carried on not long since by the Royal Artillery at Okehampton, demonstrated that this simple expedient of filling common shells with water and attaching a small charge of gun-cotton with its detonator to the fuse usually employed, allowed of their application as efficient substitutes for the comparatively complicated and costly shrapnel and segment shells.

Another illustration of the sharpness of action developed by detonation as compared with explosion, consequent upon the almost instantaneous character of the metamorphosis which the explosive agent undergoes in the case of detonation, is afforded by a method which the lecturer applied some years since for comparing the violence of action of charges of gun-cotton and of dynamite arranged in different ways. The charges (5 lb.) to be detonated were freely suspended over the centres of plates of very soft steel of the best quality, which rested upon the flat face of a massive block, or anvil, of iron, having a large central circular cavity. The distance between the upper surface of the plate and the charge suspended over it, was 4 feet. The sharp blow delivered upon the plate by the air suddenly projected against it by the force of the detonation when the charge was fired, forced the metal down into the cavity of the anvil, producing cup-shaped indentations, the dimensions of which afforded means of comparing the violence of the detonation. A much larger charge of powder exploded in actual contact with the plate, would produce no alteration of form in the metal, and the same negative result would be furnished by the explosion over the plate of a heap of loose gun-cotton of the same or greater weight than the charges detonated. The above method of experiment was devised, in the first instance by Mr. Abel, in July 1875, for comparing the quality of some specimens of Llandore steel proposed to be used by the Admiralty for ship-building purposes, with samples of malleable iron, and it has since been employed by Mr. Adamson in carrying out a very useful series of experiments, recently communicated to the Iron and Steel Institute.

It has been stated that detonation can be transmitted from one mass of gun-cotton or dynamite to another through intervening air-spaces. The extent to which such spaces can be introduced without checking detonation is obviously regulated by the size of the masses of explosive detonated; but the distances of air-space through which the detonation of a moderate quantity of the explosive agent will communicate to similar masses, are very limited, a space of 2 inches being sufficient to prevent the detonation produced by a mass of 8 oz. of gun-cotton, freely exposed, from communicating to contiguous ones. If the dispersion of force is prevented in part, and direction is given to the gases violently projected from the centre of detonation, the power of transmitting detonation to separated masses of explosive is increased to a remarkable degree. This is readily accomplished through the agency of tubes, the charge first detonated being just inserted into one extremity, while that to which the detonation is to be transmitted is inserted into the other; or separate charges may be placed at different distances inside a long tube, with long intervening spaces, the initiative charge being inserted at one end. Thus, the detonation of a 1-oz. disk of gun-cotton in open air will not transmit detonation with *certainty* to other disks placed at a greater distance than half an inch from it; but if it be just inserted into one end of an iron tube 2 feet long and 1·25 inch in diameter, a similar disk, inserted into the other extremity of the tube, will invariably be detonated. In tubes of the same kind, of very considerable length, 2-oz. disks of gun-cotton placed at intervals of 2 feet, were detonated through the initiative detonation of one such disk inserted into one extremity of the tube. The results obtained with equal quantities of gun-cotton varied with the diameter, strength, and nature of the material of the tubes used. Dynamite and mercuric fulminate, applied to their own detonation, furnished results quite analogous to those obtained with gun-cotton; but in applying fulminate to the detonation of gun-cotton through the agency of tubes, some singularly exceptional results were obtained.

Silver fulminate was employed for the purpose of instituting more precise experiments than could be made in operating on a larger scale, with gun-cotton, on the influence of the material composing the tubes, of the condition of their inner surfaces, and of other variable circumstances, upon the transmission of detonation. Half a grain of silver fulminate freely exposed and ignited by a heated body, will transmit detonation to some of the compound placed at a distance of 3 inches from it, but does not do so with certainty through a distance of 4 inches. But when the quantity of the fulminate is just inserted into one end of a stout glass tube 0·5 inch in diameter, and 3 feet long, its detonation is invariably induced by that of a similar quantity of the fulminate placed just inside the other extremity of the tube. Glass tubes were found to transmit the detonation of silver fulminate much more rapidly than tubes of several other materials of the same diameter and thickness of substance. Thus, with the employment of double the quantity of fulminate required to transmit the detonation with certainty through a glass tube of the kind described, 3 feet in length, it was only possible to obtain a similar result through a pewter tube 31·5 inches long, a brass tube 23·7 inches long, an indiarubber tube 15·8 inches long, and a paper tube 11·8 inches long. The difference in the results obtained was not ascribable to a difference in the escape of force on the instant of detonation, in consequence of the fracture of the tube, nor to the expenditure of force in work done upon the tube at the seat of detonation. The transmission of detonation appeared also not to be favoured by the sonorosity or the pitch of the tube employed, as the sonorous brass tube was not found to favour the transmission to the same extent as the pewter tube. These differences appeared on further investigation not to be ascribable, to any important extent, if at all, to the difference in the nature of the material composing the tubes, but to be simply, or at any rate almost entirely, due to differences in the condition of the inner surfaces of the tubes. Thus, brass tubes, the inner surfaces of which were highly polished, and paper tubes, when coated inside with highly glazed paper, transmitted the detonation of the silver fulminate to about the same distance as the glass tubes; on the other hand, when the inner surfaces of the latter were slightly roughened by coating them with a film of fine powder, such as French chalk, they no longer transmitted detonation to anything like the distance which they did when the inner surfaces were in the normally smooth condition. Other very slight obstacles to the unimpeded passage of the gas wave through the tubes were found greatly to reduce the facility with which detonation could be transmitted by means of tubes; thus, when a diaphragm of thin bibulous paper was inserted into the glass tube about half-way between the two extremities, detonation was not transmitted, even with the employment of about six times the quantity of fulminate that gave the result with certainty under ordinary conditions.

Among several other interesting results furnished by an examination into the conditions governing and results attending the transmission of detonation by tubes, a remarkable want of reciprocity was found to exist between mercuric fulminate and gun-cotton. The latter substance is more susceptible to the detonative power of mercuric fulminate than of any other substance. The quantity of fulminate required to detonate gun-cotton is regulated by the degree to which the sharpness of its own detonation is increased by the amount of resistance to rupture offered by the envelope in which the fulminate is confined. From 20 to 30 grains are required if the detonative agent is confined in a thin case of wood, or in several wrappings of paper; but as small a quantity as 2 grains of the fulminate suffices to effect the detonation of compressed gun-cotton, provided the fulminate be confined in a case of stout metal (sheet tin) and be closely surrounded by being tightly imbedded in the mass of gun-cotton. If there be no close contact between the two, the quantity of fulminate must be very considerably increased to ensure the detonation of the gun-cotton, and, in attempting to transmit detonation from mercuric fulminate to gun-cotton by means of tubes, it was found necessary to employ comparatively very large quantities of fulminate in order to accomplish this, even through short lengths of tubes. But when the quantity of fulminate used reaches certain limits, the detonation may be

transmitted from it to gun-cotton through very long lengths of tube. In applying gun-cotton, on the other hand, to accomplish the detonation of mercuric fulminate, it was found that this result could be attained, and through considerable lengths of tube (7 feet and upwards) by means of very much smaller quantities of gun-cotton than is needed of fulminate to induce the detonation of gun-cotton through the corresponding distances.

This want of reciprocity between two detonating agents corresponds to one even more remarkable, which was observed by the lecturer in his earlier investigations on this subject. In the first place it was found that the detonation of ¼ oz. of gun-cotton (the smallest quantity that can be thus applied) induced the simultaneous detonation of nitro-glycerine, inclosed in a vessel of sheet tin and placed at a distance of 1 inch from the gun-cotton; while with ½ oz. of the latter, the same effect was produced with an intervening space of 3 inches between the two substances. But on attempting to apply nitro-glycerine to the detonation of gun-cotton, the quantity of the former, which was detonated in *close contact* with compressed gun-cotton, was gradually increased in the first instance to ¾ oz. and subsequently even to 2 oz. without accomplishing the detonation of the latter, which was simply dispersed in a fine state of division, in all instances but one in a large number of experiments.

The force developed by the detonation of nitro-glycerine was proved to be decidedly greater than that of the fulminate, of which from 2 to 5 grains suffice for developing the detonation of gun-cotton, when it is in close contact with them. The non-susceptibility of gun-cotton to detonation by nitro-glycerine is therefore, it need scarcely be said, not ascribable to any deficiency in mechanical force suddenly applied when the nitro-glycerine is detonated.

(*To be continued.*)

INTELLECT IN BRUTES

FROM several additional letters which we have received on this subject we select the following:—

Mr. Claypole, of Antioch College, Ohio, writes:—A friend of mine is employed on a farm near Toronto, Ontario, where a horse belonging to the wife of the farmer is never required to work, but is allowed to live the life of a gentleman for the following reason: Some years ago the lady abovementioned fell off a plank bridge into a stream where the water was deep. The horse, which was feeding in a field close by, ran to the spot and held her up with his teeth till assistance arrived, thus probably saving her life. Was this reason or instinct? Again, a gentleman engaged in the business of distilling at Cincinnati has more than once told me that the rats in his distillery are in the habit of drinking any spirits spilt on the ground or left in open vessels, and that they often become, in consequence, so tipsy that they cannot run, and are easily taken by hand. Which is this?

Mr. J. J. Furniss, of New York, writes:—Since the publication of my letter (NATURE, vol. xix. p. 385) on the evidence of reasoning power in an elephant, afforded by the fact that he thatched his back with grass when exposed to the heat of the sun, I have received additional data bearing on the subject from Mr. W. A. Conklin, the superintendent of the Central Park Menagerie. I am informed by him that he has frequently observed elephants, when out of doors in the hot sunshine, thatch their backs with hay or grass; that they do so to a certain extent when under cover in the summer time, and when the flies which then attack the animals, often so fiercely as to draw blood, are particularly numerous; but that they never attempt to thatch their backs in the winter. This seems to prove that they act intelligently, and for the attainment of a definite end. It would be interesting to learn whether elephants in their wild state are in the habit of so thatching their backs. It seems more probable to suppose that in their native wilds they would avail themselves of the natural shade afforded by the jungle, and that the habit is one which has been developed in consequence of their changed surroundings in captivity. I am also informed by Mr. Conklin that when taken to the water in summer the elephants first sprinkle their bodies all over with water, and then quench their thirst. They never so sprinkle themselves in cold weather. Their reasoning in this case seems to be, "I cool my mouth by pouring water into it, now if I pour water over my back it will cool that also." Am I not justified in calling this "abstract" reasoning?

Mr. Charles Stewart, of Tighnduin by Killin, Perthshire, sends the following story:—A few years ago I kept a collie dog named "Bodach" at my farm, for herding the milk cows, and who recognised the dairy-maid as his mistress. On her directing him to keep the cows on a certain part of a field, he would lay himself down in the centre of a line fixed by him as the proper limit. Patiently and vigilantly he would remain in quietness until any of the cows passed his limit, when he would swoop down on the trespasser, take her by the heels, and drive her back. It was wonderful in how short a time the cows came to recognise and respect the arrangement. He also came to know some of the cows by name. One of them named "Aggi" required at certain seasons to be milked oftener than the others, and the dairymaid had only to say in Gaelic "Bodach, go and bring home Aggi," when he would start for the pasture, single out Aggi, and bring her carefully home.

O. J. H. sends the following:—An ordinary domestic cat was equally fond of a friend of mine and of myself. As a test, we resolved to try the following experiment. We each held a piece of bread, of the same size, shape, &c., above the eyes of the animal. He looked at each hand and its contents alternately, attempting to solve the problem of getting at the bread without exhibiting partiality for either of his friends. He at last seemed to decide upon an expedient, for, raising himself upon his hind legs, he simultaneously seized a piece of bread in each of his front paws, and conveyed the food thus obtained to his mouth. On repeating the experiment after a lapse of some time, no difficulty was experienced in dealing with the matter, as the expedient just mentioned was resorted to without a moment's hesitation.

Prof. Nipher, of Washington University, St. Louis, U.S., writes:—A friend of mine living at Iowa City, had a mule, whose ingenuity in getting into mischief was more than ordinarily remarkable. This animal had a great liking for the company of an oat-bin, and lost no opportunity, when the yard gate and barn-door were open, to secure a mouthful of oats. Finally the mule was found in the barn in the morning, and for a long time it was impossible to discover how he had come there. This went on for some time, until the animal was "caught in the act." It was found that he had learned how to open the gate, reaching over the fence to lift the latch, and that he then effectually mystified his masters, by turning round, and backing against it, until it was latched. He then proceeded to the barn-door, and pulling out the pin which held the door, it swung open of its own accord. From the intelligence which this animal displayed on many occasions, I am of the opinion that had not discovery of his trick prevented, it would soon have occurred to him to retrace his steps before daylight, in order to avoid the clubbing which the stable boys gave him in the morning. It may be added that this animal had enjoyed no unusual educational advantages, and his owners found it to their interest to discourage his intellectual efforts as much as possible.

The Rev. George Henslow endeavours to sum up as follows from the stories that have already appeared:—I am quite ready to admit that more than one instance (notably Dr. Frost's cat, which spread crumbs to catch birds, and which is paralleled by one mentioned in Wood's "Natural History," which "chirped" like a sparrow, and so enticed and caught them), if correctly stated, and *if the motive* of the animals could in every case be proved, will completely overthrow my supposition that animals never copy us with the same or a rational purpose. I cannot help thinking, however, that such cases are very rare. Moreover, I will abandon my notion of abstract reasoning, at least, as hitherto described, for I now think that what I meant by the want of the faculty would be better described as an impotence, or, at least, a feebleness of mind in concatenating correlative ideas; or, perhaps, a want of a receptivity of the suggestiveness of things will express my meaning. On the other hand, I still see no reason for believing that animals can conceive of a purely abstract idea. Thus, "V. I." says a mule would turn on a tap, but did not turn it off again. The reason I would suggest is that *wastefulness* being an abstract conception, the mule could not entertain it. If this be correct, we may now proceed a step further. The idea of a personal *Ego* is purely abstract; hence I am led to believe that no animals can be *self-conscious*, and as a direct consequence, they cannot be either moral or immoral, but are simply automata and non-moral. Like children, they can learn by being scolded, when they displease their master, so that a conscience similar to a child's can be produced in them;

yet they cannot naturally be moral. Thus, *e.g.*, self-interest is all in all with animals, but it can never lapse into selfishness, which is the *conscious* abuse of self-interest. We "punish" a dog, but we never look upon it as a criminal. So, too, no animal can ever act unjustly towards another, because it cannot be conscious either of justice or injustice. The abstract conceptions of righteousness and justice are only applicable to acts done *under a sense of righteousness and justice.* The same remark applies to personal immoralities; so that no animal can be immoral. That animals cannot entertain abstract ideas is not at all surprising, seeing how slow children are to do the same. A somewhat grotesque illustration will show this. A class of boys was asked what conscience was. None could explain it, so the teacher defined it as "something within you that tells you when you have done wrong." A boy at once exclaimed it was a stomach-ache. On inquiry it turned out that he had stolen and eaten some unripe fruit, and doubtless felt the *remorse* of conscience accordingly! If, then, my former position be qualified, I would restate it as corrected by the cases recorded as follows:—Animals reason as we do, but always in connection with concrete phenomena whether immediately apprehended by the senses, or present to consciousness through memory; but like children they are slow to perceive the suggestiveness of things. They have, morever, no power of conceiving truly abstract ideas. Hence they cannot be self-conscious, cannot conceive of God, and can neither be moral nor immoral, but are simply non-moral automata. On the other hand, that which rescues man from being an automaton pure and simple, is his power of conceiving of abstract ideas, which enables him to be self-conscious; consequently he can conceive of a personal, *i.e.* self-conscious Deity, so that he at once becomes a responsible being, and can be positively moral or immoral.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

At a recent meeting of the governors of Owens College, Manchester, the Committee on the proposed University charter presented a report. It appears that "negotiations have been actively carried on with the Council of the Yorkshire College, Leeds, partly by letter and partly by means of interviews between members of the respective committees. The suggestions agreed to by the Council of the Yorkshire College, Leeds, provide that the Owens College shall be named in the charter establishing the University as the first college in it; that the president and the principal of the Owens College shall be the first chancellor and vice-chancellor of the new University; that its *locus* shall be Manchester; and that in the system of proportionate representation proposed for the governing and the executive bodies of the University, the Owens College shall in either case begin with the maximum number of representatives allowed by the scheme." To obviate objection to a local name, that of Victoria University is suggested. The report and draft memorial were approved of, and the Committee were requested to make arrangements for the presentation of the memorial to the Lord President of the Privy Council at as early a date as possible, and for carrying out the other suggestions of the report, which was passed.

The British Medical Association are getting up a memorial to the House of Commons urging the immediate institution at Oxford of a thorough medical curriculum, on the same basis as the medical schools of other English towns, in the following subjects at least:—Human anatomy, physiology of man, general pathology, materia medica, clinical medicine and surgery for beginners, State medicine, including jurisprudence and public health.

SCIENTIFIC SERIALS

American Journal of Science and Arts, April.—An opening obituary notice of the distinguished botanist, Dr. Jacob Bigelow, who died in January, aged 92, is here followed by a note in which Prof. Marsh traces the connection between the two widely divergent forms of vertebræ of the toothed birds *Ichthyornis* and *Hesperornis.* In the former the articulation of the centrum is cup-shaped; in the latter the ends of the centrum are saddle-shaped, as in ordinary birds. The third cervical vertebra of Ichthyornis, however, has a transition form, affording a ready solution of the development of the modern avian vertebra from the fish-like. The order of development of vertebræ seems this: Biconcave vertebræ (fishes and amphibians), plane vertebræ (mammals), cup-and-ball vertebræ (reptiles), saddle vertebræ (birds).—The double stars discovered by Mr. Alvan G. Clark, which (except Sirius) have not been brought to the attention of astronomers generally, are the subject of a paper by Mr. Burnham.—Interesting details are furnished by Prof. Church of underground temperatures in the Comstock lode in Nevada, where are, apparently, the hottest mines in the world. (The rock in the lower levels seems to have a pretty uniform temperature of 130° F.)—Prof. Lesquereux contributes a review of Count Saporta's valuable work on the plants of the world before man, taking occasion to compare the essential characters of certain tertiary groups of the North American continent, in order to determine some points still under discussion as to their age.—Mr. Palsinger indicates a method of estimating the thickness of Young's reversing layer; and among other subjects dealt with are, the lower jaw of Loxolophodon and the presence of chlorine in scapolites.

Journal of the Franklin Institute, April.—We note here the following:—Reports of the Committee on Science and the Arts, on Ainsworth's automatic switch for railroads, and a machine for treating flax, hemp, &c.—Tests of a Baldwin locomotive, by Mr. Hill.—The Franklin Institute standard screw thread.—The Butler mine fire cut off, by Mr. Drinker. In the course of investigations described in this last paper, Mr. Drinker thought it established that coal *in situ cannot* be burned *en masse*, but that the walls of carbonaceous slaty rock inclosing solid coal *can* be burned or calcined *in situ.* The mining engineers who discussed his paper seemed generally to be of opinion that the slates in the old fire were not actually burned, but that the carbonaceous matter in them was rather subjected to a process of distillation.

The *Jornal de Sciencias mathematicas physicas e naturaes* (No. xxiv., December, 1878) contains the following papers:—On the oblique projection of a circle, by L. P. da Motta Pegado.—Contributiones ad floram mycologicam lusitanicam, by F. de Thuemen.—Ornithological notes, by J. V. Barboza du Bocage.—On the birds of the Portuguese possessions in West Africa (continuation), by the same.—On electrical condensation and the condensing force, by A. A. de Pina Vidal.—On a new densimeter, by Virgilio Machado.

The quarterly *Revue des Sciences naturelles* (tome vii. No. 4) contains the following original papers:—Morphological researches on the family of *Gramineæ*, by D. A. Gordon.—Note on the genital organs and the propagation of some *Limacidæ*, by S. Jourdain.—Observations on the destruction and the development of the ovigerous capsule of *Blatta orientalis*, by G. Duchamp.—Catalogue of the land and river molluscs of the Hérault department, by E. Dubrneil (continuation).—Note on the soil of Montpellier, by P. de Rouville.—Note on the Pyrenees of the Aude, by M. Leymerie.

SOCIETIES AND ACADEMIES

London

Royal Society, March 6.—"On the Characters of the Pelvis in the Mammalia, and the Conclusions respecting the Origin of Mammals which may be based on them." By Prof. Huxley, Sec. R.S., Professor of Natural History in the Royal School of Mines.

In the course of the following observations upon the typical characters and the modifications of the pelvis in the mammalia, it will be convenient to refer to certain straight lines, which may be drawn through anatomically definable regions of the pelvis, as *axes.* Of these I shall term a longitudinal line traversing the centre of the sacral vertebræ, the *sacral axis;* a second, drawn along the ilium, dorso-ventrally, through the middle of the sacral articulation and the centre of the acetabulum, will be termed the *iliac axis;* a third, passing through the junctions of the pubis and ischium above and below the obturator foramen, will be the *obturator axis;* while a fourth, traversing the union of the ilium, in front with the pubis, and behind with the ischium, will be the *iliopectineal axis.*

The least modified form of mammalian pelvis is to be seen, as might be expected, in the Monotremes, but there is a great difference between *Ornithorhynchus* and *Echidna* in this respect, the former being much less characteristically mammalian than the latter.

The distinctive features of the mammalian pelvis have been

clearly indicated by Gegenbaur,[1] who points out that in mammals, in contradistinction from reptiles, "the longitudinal axis of the ilium gradually acquires an oblique direction, from in front and above, backwards and downwards. The part which represents the crista above thus becomes turned forwards, or more or less outwards, with increase of lateral surface, the acetabular part backwards and downwards; hence the ischium retains its original direction in the produced long axis of the ilium, and, at the same time, takes up a position in relation to the vertebral column similar to that which obtains in birds. The conditions of this position are, however, to be sought in factors of a totally different nature in mammals from those which produce it in birds; for, in the former, the ischium follows the changed direction of the ilium, whilst in birds the ilium has nothing to do with the matter, and the ventral elements of the pelvis appear to pass towards the caudal region, independently of the ilium."

On one point, however, I cannot agree with Gegenbaur's conclusions. He is of opinion that the ilium of mammals answers to the post-acetabular part of the ilium of birds, and that "the *crista ossis ilii* of mammals corresponds with the posterior edge of the post-acetabular part of the bird's ilium. Between the two parts, therefore, there is the difference of a rotation through an angle of almost 180°." On the contrary, it appears to me evident that the whole *crista ilii* in a mammal corresponds with the whole dorsal edge of the ilium in a bird or a reptile, and that the angle through which the iliac axis rotates amounts to not more than 90°. I cannot reconcile the contrary view either with the relations of the ilium to the sacrum, or with the attachment of the muscles.

On comparing the pelvis of *Ornithorhynchus* with that of a lizard, or that of a chelonian, it will be observed that the resemblance between the former and the sauropsidan pelvis is, in most respects, closer than that which it bears to the higher mammalian pelvis. In the reptiles both the pubes and the ischia unite in a ventral symphysis; the pubis has a strong pectineal process, which acquires very large dimensions in the *Chelonia;* the metischial processes are also often very strong. Nevertheless, there is an important difference, for in all these animals the iliac axis is either nearly perpendicular to the sacral axis, or slopes from above downwards and forwards; the obturator axis also inclines downwards and forwards. Hence in most *Lacertilia* and *Chelonia*, the pubes slope forwards very obliquely, while the ischia come more and more forwards.

In other words, such modifications of the pelvis as occur in the Lacertilia and the Chelonia are of an opposite kind to those which take place in mammalia.

The same thing is true of the *Crocodilia*.

Thus it appears to be useless to attempt to seek among any known Sauropsida for the kind of pelvis which analogy leads us to expect among those vertebrated animals which immediately preceded the lowest known mammalia. For, if we prolong the series of observed modifications of the pelvis in this group backwards, the "pro-mammalia" antecedent to the Monotremes may be expected to have the iliac and obturator axis perpendicular to the sacral axis, and the iliopectineal axis parallel with it; something, in short, between the pelvis of an *Ornithorhynchus* and that of a land-tortoise; and provided, like the former, with large epipubes intermediate in character between those of the lower mammals and those of crocodiles. In fact, we are led to the construction of a common type of pelvis, whence all the modifications known to occur in the Sauropsida and in the mammalia may have diverged.

It is a well-known peculiarity of the urodele amphibia, that each *os innominatum* consists of a continuous cartilage, the ventral half of which is perforated by a foramen for the obturator nerve, but has no large fibrous fontanelle or obturator foramen in the ordinary sense of the word. As the junction of the dorsal with the ventral moiety, the acetabulum marks off the iliac portion of the pelvic arch above, from the pubic and ischial regions below; and these are further distinguishable, even apart from their ossifications, by the position of the foramen for the obturator nerve and the origins of the muscles. In full-grown specimens of *Salamandra maculosa* the pelvis presents the following characters:—The iliac axis is slightly inclined forwards, while the iliopectineal axis is practically parallel with the sacral axis. The iliac ossification extends into the acetabulum, and forms a triangular segment of its roof with the apex downwards, exactly as in lizards. The posterior and inferior side of the triangle is separated by a thin band of the primitive cartilage from the upper edge of the similarly triangular cotyloid end of the ischial ossification, the anterior edge of which is vertical again as in lizards. Between this edge and the anterior and inferior edge of the iliac ossification there is a cartilaginous interspace, as in crocodiles, which represents the cotyloid end of the pubis. This cartilaginous part of the pubis gives rise to a pectineal process, which has the same position as in birds and in *Ornithorhynchus*. In the floor of the acetabulum the pubic ossification makes its appearance as a very thin lamina, which extends, underneath the pectineal process, inwards; and gradually surrounds the whole of the thickened transverse ridge of cartilage which corresponds with the pubis. The pubis is thus represented by an axis of cartilage surrounded by bone, and the thick inner extremities of the two pubes are largely united by fibrous tissue. The ischia are relatively large, and are united, partly by cartilage and partly by ligament, in a long symphysis. Their posterior and external angles are produced into short metischial processes. In one specimen I observed a distinct sutural line between the anterior curved edge of the right ischium and the corresponding pubis, while no such suture could be traced upon the other side.

The pelvic arch of *Salamandra*, therefore, contains all the elements which are found in the higher vertebrata, but the obturator fontanelle is wanting, and it seems to me that in such a pelvis we have an adequate representation of the type from which all the different modifications which we find in the higher vertebrata may have taken their origin.

In the lizards and the *Chelonia* the iliac and obturator axes have inclined forwards, and the epipubes have been reduced to such rudiments, as have been described in chameleons and in some tortoises.[1]

In the crocodiles, with the same general pelvic characters, the cotyloid end of the pubis retains its imperfectly ossified condition, while the epipubes represent the vastly enlarged rami of the salamandrine epipubis.

In the Ornithoscelida and in birds, the ilia elongate, but it is the modification of the pubes and ischia which is the most characteristic feature of the pelvis, and the epipubis vanishes.

In the Pterosauria and in the Dicynodonts, the salamandrine non-development of an obturator fontanelle persists; and, in the former, the sessile rami of the epipubis appear to be represented by the so-called marsupial bones.

Unless the like should prove to be the case in the Dicynodonts, it is in the mammalia alone that the subsacral portion of the ilium elongates backwards, carrying with it the pubis and the ischium, between which a large rounded obturator fontanelle is developed.

These facts appear to me to point to the conclusion that the mammalia have been connected with the amphibia by some unknown pro-mammalian group, and not by any of the known forms of Sauropsida; and there is other evidence which tends in the same direction.

Thus, the amphibia are the only air-breathing vertebrata which, like mammals, have a dicondylian skull. It is only in them that the articular element of the mandibular arch remains cartilaginous; while the quadrate ossification is small, and the squamosal extends down over it to the osseous elements of the mandible; thus affording an easy transition to the mammalian condition of these parts.

The pectoral arch of the Monotremes is as much amphibian as it is sauropsidan; the carpus and the tarsus of all Sauropsida, except the Chelonia, are modified away from the urodele type, while those of the mammal are directly reducible to it; and it is perhaps worth notice, that the calcar of the frogs is, in some respects, comparable with the spur of the Monotremes.

Finally, the fact that in all Sauropsida it is a right aortic arch which is the main conduit of arterial blood leaving the heart, while, in mammals it is a left aortic arch which performs this office, is a great stumbling-block in the way of the derivation of the mammalia from any of the Sauropsida. But if we suppose the earliest forms of both the mammalia and the Sauropsida to have had a common amphibian origin, there is no difficulty in the supposition that, from the first, it was a left aortic arch in the one series, and the corresponding right aortic arch in the other, which became the predominant feeder of the arterial system.

The discovery of the intermediate links between reptilia and

[1] "Beiträge zur Kenntniss des Beckens der Vögel," *Jenaische Zeitschrift* vi.

[1] Hoffman, "Beiträge zur Kenntniss des Beckens der Amphibien und Reptilien," *Nied. Archiv für Zoologie*, 1876.

aves, among extinct forms of life, gives every ground for hoping that, before long, the transition between the lowest mammalia at present known and the simpler vertebrata may be similarly traced. The preceding remarks are intended to direct attention to the indications of the characters of these pro-mammalian vertebrata, which the evidence at present forthcoming seems to me to suggest.

In the relatively large size of the brain, and in the absence of teeth, the only existing representatives of the Ornithodelphia present characters which suggest that they are much modified members of the group. On comparing the brain of *Echidna*, for example, with that of many marsupialia and insectivora, its relative magnitude is remarkable: and, in view of the evidence which is now accumulating, that the brain increases in size in the later members of the same series of mammalia, one may surmise that *Echidna* is the last term of a series of smaller-brained Ornithodelphia. Among the higher vertebrata I think that there is strong reason to believe that edentalous animals are always modifications of toothed forms.

Institution of Civil Engineers, April 22.—Mr. Bateman, president, in the chair.—The paper read was on dioptric apparatus in light-houses for the electric light, by Mr. James T. Chance, Assoc. Inst. C.E.

PARIS

Academy of Sciences, April 24.—M. Daubrée in the chair.—The following papers were read:—On the condition of the roadstead of Port Said, by M. De Lesseps. The bottom appears to have reached a state of equilibrium, and the dredging operations carried out annually will suffice to maintain this state. The sand deposits, opposed by dredging, are chiefly formed to the north and north-east of the large jetty, in a region reaching about 800 to 1,000 metres from its base. Beyond this, as also to the west, the deposits are more muddy, and are carried away by the action of the sea. M. De Lesseps also spoke hopefully of the Congress to meet on May 15, for determining the best course for an inter-oceanic canal (which he thinks will be achieved before the close of this century).—Complementary researches on the products of distillation of alcohols, by MM. Pierre and Puchot. The authors reproduced synthetically most of the phenomena observed, by operating on aldehydes.—On the navisphere, a nautical instrument, by M. De Magnac. This gives, without calculation, and in a few seconds, the names of the stars that are above the horizon at a given moment; also very approximately, the altitudes and azimuths of these stars; also the angle of route for going from one point to another by the arc of a great circle, and the distance between these points. The instrument has been tried on the steamship *Washington* with excellent results.—Experimental researches on the metallic grains of sporadosideric meteorites, by M. Meunier. The grains are essentially angular and branching, and do not seem to have passed through fusion. They often form envelopes round stony elements of cosmic rock. The Greenland masses of native iron (whose grains are of this character) cannot be thought the product of reduction of the dolerite by the lignite through which they have been erupted. M. Meunier considers them brought from a great depth with ordinary basalt, in which they had been embedded.—On the artificial production of bioxide of manganese, by M. Gorgeu. Artificial bioxide, having all the properties of polianite and pyrolusite, was got by heating, gently and long, at a temperature of 155° to 162°, nitrate of manganese in a glass phial placed in a bath of oil or paraffin. Other methods were tried without success. The authors are of opinion that, in formation of polianite and pyrolusite, the iron suspended in the very fluid mass of fused nitrate of manganese was decanted before decomposition of the nitrate occurred; and the same with all other powdery products mixed with the nitrate.—On tritungstates, by M. Lefort.—On the methodic employment of coloured glasses in achromatopsy, by M. Coursserant. May not the exclusive excitation of certain nerve elements of the retina cause to be produced and accumulated, in certain elements in repose, a quantity of work which will manifest itself in the form of variously coloured light, when these rested elements, solicited in turn, come into action?—Observations of Jupiter's satellites, at the Toulouse Observatory in 1878, by M. Baillaud.—Formation of a function, $F(x)$, possessing the property $F[\phi(x)] = F(x)$, by M. Appel.—Letter to M. Dumas on the apparatus of Lavoisier, by M. Truchot. The Conservatoire des Arts et Métiers contains about a dozen of Lavoisier's instruments, chiefly relating to synthesis of water and calorimetry. But this is not all that remains; his chemical laboratory and physical cabinet have been piously preserved by his family. They are now in possession of M. de Chazelles, at Canière, near Aigue-perse (Puy de Dôme), and M. Truchot has made an inventory of them, which he here gives briefly. Many of the instruments are of great interest.—Chemical function of anhydrous acetic acid, by M. Loir. It presents the general properties characterising aldehydes.—On nitrosoguanidine, by M. Jousselin. He indicates a method of obtaining it in considerable quantities, and describes several of its reactions.—On the value of certain chemical agents employed in dyeing with aniline black, by M. Witz. The proved inertia of chromium in mixtures with chlorates contrasts singularly with the marvellous energy of vanadium, the industrial use of which presents the greatest economical advantages.—On the formation of hail, by M. Oltromare. Suppose the temperature of a considerable cloudy mass (formed by cooling and condensation of saturated air and electricity keeping the molecules apart) to go down to − 14°, implying a state of *surfusion*,—and the electricity of the mass suppressed by discharge, the molecules then clashing together will be changed into pieces of ice more or less coherent.—On the amyloid appearance of cellulose in champignons, by M. de Seynes.—On the mode of formation of biliary canaliculi in hepatitis, and the consecutive production of tubulated glands in the liver of the rabbit, by MM. Nicati and Richaud.—M. Jaubert claimed priority with regard to the MM. Henry's new catadioptric telescope. M. Faye pointed out, however, that MM. Henry did not seek to modify the optical power of reflectors by addition of a large refracting lens, but simply to close the tube so as to suppress movements of the interior air.—M. Larry presented the catalogue of the South Kensington Loan Collection (third edition), accompanied with a French Guide.

VIENNA

Imperial Academy of Sciences, March 6.—The following among other papers were read:—On the new recurrence of halotrichite and melanterite at Idria, by Prof. Zepharovich.—On the electrical perforation of glass, by Prof. Waltenhofen.—On the decomposition of formiate of ammonium at a high temperature, by Herr Andreasch.—On determination of the co-efficient of internal friction in viscous liquids by gravitation experiments, by Herr Schröttner.—On direct introduction of carboxyl groups into phenols and aromatic acids, by Prof. Senhofer and Dr. Brunner.—On facts of experience lying at the base of mechanics, by Herr Heller.—Muscular system of the extremities of the orang, by Prof. Langer.—On lacunar consumption of striped muscular fibres, by Prof. Klemmsiewicz.—Eruptive rocks of the western Balkans, by Prof. Niedzwiedzki.—Theory of the metallic thermometer, by Herr Jüllig.

March 13.—Remarks on the telephone, by Prof. Boltzmann.—On a new substance, nitroso-sulphhydantoin, by Prof. Naly and Herr Andreasch.—On resorcin-sulpho-acids, by Herr Fischer.

THE CHEMISTRY OF COMMON LIFE

The Chemistry of Common Life. By the late James F. W. Johnston, M.A., F.R.S., Professor of Chemistry in the University of Durham. A new edition, revised and brought down to the present time. By Arthur Herbert Church, M.A. (Blackwood and Sons, Edinburgh and London, 1879.)

IT is now a great many years since the writer of the present review first read the work which as edited by Prof. Church he wishes to introduce to the readers of NATURE. He has not forgotten the keen interest and pleasure which the book awakened in him as a boy, and which were re-awakened when a few weeks ago the new volume came into his hands. Though times have changed since this book was published—now twenty-five years ago—though we are now almost deluged with scientific manuals and primers, intended to gratify the growing taste for science, or rather, perhaps, to meet the needs of our quasi-Chinese examination systems, yet such books as Johnston's "Chemistry of Common Life," or the equally charming companion work, "The Physiology of Common Life," by the late G. H. Lewes, have not been superseded. Full of facts which it is often difficult to find elsewhere, written in a style which will charm the most fastidious, awakening at every step the reader's desire to know more of the subject which is treated of, these two works have always appeared to us very models of popular scientific writing.

To edit such a work as "The Chemistry of Common Life" so as to bring the book up to date without departing from the author's plan or awakening unpleasant comparisons, was by no means an easy task, and one which could only be discharged adequately by an easy writer, thoroughly conversant with chemistry, and not unfamiliar with physiology; the task has, we think, been admirably performed by Mr. Church, and we recommend the volume which he has edited as one eminently deserving of the study of the medical man and the student of physiology.

The first chapter treats of "The Air we Breathe." In it we find discussed the composition of the atmosphere, the mode of preparation, and properties of its constituent gases; the importance of the watery vapour of the air, the formation of rain and dew, and their many uses; the accidental constituents of the air. The second chapter is devoted to "The Water we Drink." Here we find discussed the properties of hydrogen, the differences between a chemical compound and a mechanical mixture, the powers of water as a solvent, the quantities of mineral matter in some river, lake, spring, and sea waters; the causes of the hardness of waters, the organic impurities of water, the solubility of gases in water, and the importance of the presence of oxygen in water in relation to the life of fishes, besides many other topics which cannot be enumerated.

As an example of the way in which interesting information is brought together and ingenious suggestions advanced, which are sure to arouse an inquiring spirit in the reader, we quote the following very characteristic discussion of the influence exerted by certain vegetable matters upon the organic matters of water, with an ingenious explanation of the mystery of the waters of Marah:—

"Well-waters sometimes contain vegetable substances also of a peculiar kind, which render them unwholesome, even over large tracts of country. In sundry districts the decaying vegetable matters of the surface soil are observed to sink down and form an ochreous *pan*, or thin yellow layer, in the sub-soil, which is impervious to water, and through which, therefore, the rains cannot pass. Being arrested by this pan, the rain-water, while it rests upon it, dissolves a certain portion of the vegetable matter, and when collected into wells, is often dark-coloured, marshy in taste and smell, and unwholesome to drink. When boiled, the organic matter coagulates, and when the water cools, separates in blocks, leaving the water wholesome and nearly free from taste or smell. The same purification takes place when the water is filtered through charcoal, or when *chips of oak wood are put into it.* These properties of being coagulated by boiling, and by the tannin of oak wood, show that the organic matter contained in the water is of an albuminous character, or resembles white of egg. As it coagulates, it not only falls itself, but it carries other impurities along with it, and thus purifies the water—in the same way as the white of egg clarifies wines and other liquors to which it is added.

"Such is the character of the waters in common use in the *Landes* of the Gironde around Bordeaux,[1] and in many other sandy districts. The waters of rivers and of marshy and swampy places often contain a similar coagulable substance. Hence the waters of the Seine at Paris are clarified by introducing a morsel of alum, and the river and marshy waters of India by the use of the nuts of the *Strychnos potatorum* of which travellers often carry a supply. One of these nuts, rubbed to powder on the side of the earthen vessel into which the water is to be poured, soon causes the impurities to subside. In Egypt the muddy water of the Nile is clarified by rubbing bitter almonds on the sides of the water-vessel in the same way.

"In these instances the clarification results from the iron compounds or the albuminous matter being coagulated by what is added to the water, and in coagulating, it embraces the other impurities of the water, and carries them down along with it. Salt, and many saline matters, have likewise the power of clearing many kinds of thick and muddy water. So long as the water contains but little dissolved matter, all its particles of mud remain a long time suspended. But the addition of almost any soluble salt, even in small proportion, will, as it were, curdle the impurities, causing them to collect together and to settle.

"These cases, and especially that of the sandy Landes of Bordeaux, and elsewhere, throw an interesting light upon the history of the waters of Marah, as given in the fifteenth chapter of Exodus—

"'So Moses brought Israel from the Red Sea, and they went out into the wilderness of Shur; and they went three days in the wilderness, and found no water. And when they came to Marah, they could not drink of the waters of Marah, for they were bitter: therefore the name of it was called Marah. And the people murmured against Moses, saying, What shall we drink? And he cried unto the Lord, and the Lord showed him a *tree*, which when he had cast into the waters, the waters were made sweet.'"[2]

The chapter on Water is followed by others which treat of "The Soil we Cultivate and the Plants we Rear," of "The Bread we Eat" and "The Beef we Cook." Under the heading of "The Beverages we Infuse" we find separate chapters allotted to "The Teas," "The Coffees," "The

[1] Fauré—*Annales de Chim. et de Phys.*, Septembre, 1853, p. 84.
[2] Exodus, xv. 22–25.

Cocoas," the natural history, the various modes of preparation, the chemical composition, the physiological action, and the dietetic uses being in each case satisfactorily and pretty fully discussed.

"The Sweets we Extract" have several chapters devoted to them, in which the chemistry of the sugars is treated of, and the various methods of preparing cane, maple, beet-root, and even manna and milk-sugar are fully described.

"The Liquors we Ferment" include "The Beers," "The Wines," and "The Brandies." Under each head we find an amount of general information relating to modes of manufacture, to chemical composition, and to habits of various nations, which is truly remarkable.

"The Narcotics we Indulge in" have eight chapters devoted to them, the subjects treated of being the following:—tobacco; the hop and its substitutes; the poppy and the lettuce; Indian hemp; the betel nut and the pepperworts; coca; the Siberian fungus, and the minor narcotics. Then follow "The Odours we Enjoy," "The Smells we Dislike," and "The Colours we Admire." The last-named chapter is entirely new, and we shall therefore notice it at somewhat greater length than its predecessors.

It appears to us rather a mistake to have classed the blood colouring matter under the heading of "The Colours we Admire;" beautiful though the colour of blood may appear to be to the physiologist, we doubt very much whether most persons would not object to the statement implied in the classification adopted. As the proximate principle which confers upon the coloured blood corpuscles their remarkable function as the oxygen-carriers of the body, it ought in our opinion to have been relegated to the chapter which treats of "What we Breathe and Breathe for." In connection with hæmoglobin, though not in the chapter now under discussion, we find one of the really few inaccurate statements with which we have to charge Mr. Church. "But if the carbon-containing substances derived from man's food are burnt throughout his body, and if this burning takes place because of oxygen brought from the lungs, how and in what forms, may we ask, are the products of this burning, being no longer of use, conveyed out of the body? The very hæmaglobin which has brought the oxygen carries away the chief product of the burning—namely, carbonic acid gas." This is not correct.

Hæmoglobin possesses no special power of absorbing carbon dioxide, and the greater part of this body as it is formed, is taken up by the liquor sanguinis in which it is held partly in a state of solution and partly of feeble chemical combination. We observe that Prof. Church applies to the blood colouring matter the term hæm*a*globin instead of hæm*o*globin. The second is the now universally adopted way of spelling the word; it is a barbarously coined word and can only be preferred to the etymologically more correct hæmato-globulin on the score of use and wont; the change made by Mr. Church is, however, surely no improvement, as it is the stem (*αἱματ-*) and not the nominative case (*αἷμα*) which should be incorporated in the compound word. In the words "hæmorrhage," "hæmorrhoidal," "hæmoptysis," we have at least the sanction of old usage given to the coiners of "hæm*o*globin."

After shortly describing hæmoglobin Mr. Church refers to Turacin, a very remarkable red colouring matter containing 8 per cent. of copper, which he discovered several years ago in the pinion feathers of the *Plantain-eaters.* "The existence of an animal pigment so rich in copper as turacin, offers many interesting problems for study. Traces of this metal seem generally diffused in most vegetables and many animals; but here are more than traces—weighable and visible quantities." The sheets of the book had probably passed through the press before the announcement of Dr. Frederique's recent discoveries had been made in reference to the blood of the octopus, which would otherwise have probably been noticed. Dr. Frederique, of Ghent, in the first place confirmed the observations made by previous writers as to the colour of the blood of the octopus; in this creature the arterial blood is blue, whilst the venous blood is colourless. On agitating the venous blood with oxygen or atmospheric air it becomes blue; conversely on treating the blue arterial blood with reducing agents or heating it in the vacuum of a mercurial pump it loses its blue colour. The colour is found by Frederique to be due to a complex body containing copper, to which he has given the name hæmocyanin, which appears to have an analogous constitution to hæmoglobin; like this body it is decomposed easily and yields a proteid body and a colouring matter which contains all the copper of the original substance. This copper containing proximate principle is dissolved in the plasma and is undoubtedly the oxygen carrier of the blood of the octopus.

The chapter on "The Colours we Admire" closes with a succinct account of the synthesis (by Graebe and Liebermann) of alizarin, the madder pigment, and by a notice of recent researches on the constitution of certain of the coal-tar colours.

Did space permit we should notice the concluding chapters, of which some are mainly devoted to certain physiological topics, others to a recapitulation on "The Circulation of Matter." We trust, however, that the sketch which we have given will suffice to give some idea of the wide scope and deep interest which attaches to Mr. Church's admirable edition of "The Chemistry of Common Life." A. G.

SILURIAN FOSSILS

A Monograph of the Silurian Fossils of the Girvan District in Ayrshire, with Special Reference to those contained in the "Gray Collection." By H. Alleyne Nicholson, M.D., D.Sc., F.R.S.E., Professor of Natural History in the University of St. Andrews, and Robert Etheridge, Jun., F.G.S., Acting-Palæontologist to the Geological Survey of Scotland. Fasciculus I. *Rhizopoda, Actinozoa, Trilobita.* Pp. 135, Pl. i.-ix. (Blackwood and Co., 1878.)

THE authors of this monograph state in their preface that they have been enabled to undertake their task through the aid rendered to them by a grant from the Government fund administered by the Royal Society, and we cannot but feel in examining this first instalment of the result of their labour that the pecuniary assistance has been in this case exceedingly well bestowed.

The Silurian district of Girvan in Ayrshire is one that has attracted much attention from geologists, and considerable difference of opinion has existed as to the exact correlation of the several members of the formation as there exhibited with the equivalent English deposits. The fossils, though numerous, are often in a rather unsatisfactory condition as regards preservation, and it was most desirable that a careful study of all the known forms should be made by competent palæontologists. The richly stocked cabinets of Mrs. Robert Gray have furnished the larger part of the specimens described, and the completion of this first part of the work was rendered possible by the liberality of Mr. Gray.

The memoir commences with an account of the bibliography of the subject, which appears to be very full and complete, and then proceeds to the description of the lower forms of life. Any one who will take the trouble to compare the lists given by our authors with those previously published cannot but be struck by the large additions which are now made to the Girvan Silurian fauna. A single doubtful fucoid and four species of *Foraminifera* are described as occurring in the Girvan rocks, and among the latter is the remarkable *Saccammina carteri*, which is so excessively abundant in some of the Carboniferous limestones. This form has been recognised as identical with the Carboniferous type by Mr. H. B. Brady himself, and its existence in Silurian strata adds another example—one of great interest to geologists—of the wide range in time of some of the lower forms of life.

Among the corals from the Girvan area Messrs. Nicholson and Etheridge enumerate no less than twenty-two forms, some being old and well-known species, but the majority are new to science; indeed several new genera of Actinozoa are established in the present work. The specimens are usually in a bad state of preservation, a difficulty which has been to some extent overcome by the authors by the employment of thin sections. The fact which comes out most strikingly from the study of the Cœlenterate fauna of the Girvan beds is that the nearest analogues of the Silurian fossils of Scotland are to be found not in the English area but in the American. The same fact, it will be remembered, was made very strikingly manifest from Mr. Salter's studies of the fauna of the Silurian limestone of Durness in Sutherland.

Of Trilobites twenty-eight species are now described as occurring in the Girvan district, and among them several forms new to science have been detected.

As the present volume only contains the first part of the results of our author's labours we do not find a full discussion of the bearing of the palæontological evidence on the interesting question of the age of the several Girvan deposits. There can be no doubt, however, that both the Upper and Lower Silurian are there represented, though the exact correlation of the different members of the series can only be successfully attempted when the fossils have been more fully worked out.

The present fasciculus is illustrated by nine very well executed lithographic plates from the pencil of Mr. Charles Berjean. We congratulate the authors on the able manner in which they have executed this first portion of their task, and hope soon to have to record the appearance of other portions of this important monograph.

OUR BOOK SHELF

Natural History Rambles. The Sea-Shore. By Prof. P. M. Duncan, F.R.S. *Lane and Field.* By the Rev. J. G. Wood. *Underground.* By J. E. Taylor, F.L.S. *The Woodlands.* By M. C. Cooke, LL.D. (London: S.P.C.K., 1879).

THESE four handy little volumes are well put together, and seem to us decidedly superior to works of a similar kind with which we used to be familiar in our youth. The evident purpose of the volumes is not to teach their subjects systematically, but to lead those into whose hands they may fall to take an interest in the common objects of nature which may be met with in an occasional walk. For this purpose they seem to us well adapted, and the information they convey on the whole trustworthy. They abound in suitable and well-executed illustrations, and might appropriately be put into the hands of any one, old and young, whose circumstances would give him a chance of using them.

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts. No notice is taken of anonymous communications.*

[*The Editor urgently requests correspondents to keep their letters as short as possible. The pressure on his space is so great that it is impossible otherwise to ensure the appearance even of communications containing interesting and novel facts.*]

Brorsen's Comet

LAST night, May 3, I observed Brorsen's comet pass nearly centrally over the star DM, + 61°, No. 873. In the principal focus of the telescope were two straight bars, 43″ (seconds of arc) wide intersecting in the centre of the field. The bars are at right angles to one another, and were inclined 45° to the hour circle. With this arrangement it was easy, by moving the telescope gently about the polar axis (which is well adjusted), to determine the conjunctions in R.A. and in declination, while angles of position coinciding with the bars, and distances in parts of the breadth of a bar, could be estimated with considerable accuracy. In this manner I made the following observations of the position of the comet with reference to the star:—

Chronometer time. h. m. s.	Angle of position. °	Dist. ″	
10 2 59	260	33	Distance measured by beats of chronometer.
10 4 31	270	12	Ditto.
10 6 20	—	—	Star apparently central in comet.
10 7 30	320	10	Star a little right of centre.
10 11 30	0	—	Estimated conjunction in R.A.
10 16 0	45	16	
10 18 15	45	43	
10 20 30	45	65	

Projecting these observations on a chart of ruled squares, it appears that at 10h. 11m. 36s. (corresponding to 10h. 11m. 14s. G.M.T.) the comet followed the star 0·68s. in R.A. and was 12″ N. of it, while the nearest approach of the centre of the comet to the star was 7″ at about 10h. 7m.

The moon was shining with great brilliancy (being nearly full) and made the comet faint, reducing its apparent diameter to 1½ or 2 minutes. The star is given in the DM as of the 8·8 magnitude, but I think is underrated a little. While the comet was passing over it there was no sensible diminution of its lustre. The DM position of the star for 1855·0 is—

$$\alpha = 6h.\ 7m.\ 25s.,\ \delta = +\ 61°\ 28'·9.$$

The light of the comet has diminished rapidly since April 4. It is now less bright than a 9th mag. star.

Blackheath G. L. TUPMAN

IT is to be hoped that while the comet remains with us the observations of Prof. Young (NATURE, vol. xix. p. 559), and of Mr. Christie (NATURE, vol. xx. p. 5) may be repeated and confirmed by those who possess telescopes of sufficient power.

May I trespass upon your space so far as to ask Mr. Christie to explain a little more clearly what the precise carbon bands are with which the bands in the comet-spectrum are coincident. He speaks of the less-refrangible edge of the brightest comet band coinciding with the corresponding edge of the green carbon-band at 5200—in the spectrum of an alcohol vacuum-tube—and then proceeds to remark that the bands in the spectrum of alcohol are identical with those in the spectrum of olefiant gas and of carbon-dioxide and carbon-monoxide. If we are to understand that all the gases are inclosed in vacuum-tubes, then it must be remembered that the spectrum they give is the second spectrum of carbon in which the brightest bands have the wave-lengths 5610·5, 5198·4, 4834, and 4505. But it appears from Prof. Young's comparison of the comet spectrum with the blue flame of a Bunsen burner, that the brighter band agrees with that of the first spectrum of carbon whose wave-length is 5165·5 within about the interval of the *b* lines

$$(b_1 - b_4 = 5183·0 - 5166·7 = 16·3).$$

The spectrum with which Huggins compared the spectrum of Comet II. 1868, and of Coggia's comet in 1874, was obtained by taking the spark in olefiant gas at the ordinary pressure, and is therefore again the first spectrum of carbon.

The following comparison will exhibit the uncertainty which I wish to have explained :—

Position of least refrangible Edges of Bands.			
Brorsen's comet	5600	5200	—
Carbon spectrum I.	5634·7	5165·3	4739·8
Carbon spectrum II.	5610·5	5198·4	4834

May I suggest the following comparison : to bring up the occulting bar from the blue end of the spectrum till it just covers the brightest comet band, then to introduce into the telescope first the light from a Bunsen burner or blowpipe flame, and then that from a vacuum tube inclosing carbonic oxide.

If the comet spectrum is that of Carbon I., light will be seen in the second case, but none in the first ; if it be that of Carbon II., no light will be seen in either case.

Giggleswick, May 5 WILLIAM MARSHALL WATTS

I CAN fully confirm Young's observation that the spectrum of Brorsen's comet is not now the same as that observed by Huggins in 1868, as figured in Roscoe's "Spectrum Analysis," p. 251. On the 28th and 30th I observed the spectrum with a Browning's "miniature spectroscope" on a 4½-inch refractor, and compared it with the carbon spectrum of a low gas flame, and found the three usual bands of the latter to coincide with the three bands of the comet as completely as my instruments would show. It was needful to use a wide slit. T. W. BACKHOUSE

Sunderland, May 6

Temperature Equilibrium in the Universe in Relation to the Kinetic Theory

I AM inclined to think I shall best answer Mr. W. Muir's letter by not disputing the vague charges of unsoundness he has brought against me, but in endeavouring to make more clear the position for which I contend.

The object of my paper (NATURE, vol. xix. p. 460) was to contest the necessity of supposing that existing physical principles must have been violated in past time. I sought to prove that there was no reality in this necessity, by showing that even from our present imperfect knowledge, an explanation for the existing state of things might be evolved consistent with principles which at present prevail. Perhaps I may do well to add a few words in order to elucidate a point which was not too clearly expressed.

For mere sake of illustration, let us imagine a spherical envelope which permits neither change of volume nor passage of heat, to inclose a space of diameter, say 10^{10} times the distance between the sun and Sirius. First, let all the matter within this space be at the zero of temperature. Second, let all the matter within our envelope be at such a temperature that it is entirely dissociated into discrete molecules. Between these two extremes there is room for any number of mean states in which matter might be more or less aggregated, or discrete, and my point was that the universe might actually be in one of these intermediate states. It should be scarcely necessary to observe that we have limited our space merely for the sake of fixing our ideas. All that we require is gained, if, instead of using the impermeable envelope, we surround our sphere with infinite space filled with matter in a similar condition to that which the sphere inclosed. It is important to note that the volumes must be taken large enough to form a fair sample of the general state of the universe. Prof. Clerk Maxwell has shown ("Theory of Heat," p. 328) that a demon existing inside a gas might find irregularity where to us giants all appears uniform. With respect to the universe, may we not be in the position of demons?

London, April 29 S. TOLVER PRESTON

Barometric Pressure and Sun-Spots

IN his letter to NATURE, vol. xviii. p. 567, on "Sun-Spots and Weather," Mr. Fred. Chambers has shown that the curve of mean barometric pressure at Bombay throughout the year varies with the inverted sun-spot curve. Taking this fact together with the commonly-received idea that the annual variation of barometric pressure in Central Asia is due to the corresponding annual variation of solar radiation, he thence concludes that "the sun is hottest about the time that the spots are at a maximum, and coldest about the time when they are at a minimum." Now, even if the validity of the logical process by which "secular" is substituted for "annual" in this argument be admitted to hold in a general way, have we any reason to suppose that the atmospheric conditions at Bombay, a marine station on a peninsula, can be adequately taken to represent those which prevail in the centre of the Asiatic continent, or that they approximate to the latter to any greater extent, or even as much as those at St. Petersburg, for example?

On the other hand, if conditions which presumably reach their maximum intensity in the centre of the continent are so distinctly marked at such a distance from it as Bombay, they should at least be visible to some extent at St. Petersburg, which is certainly more continental in position, if not actually nearer the centre of the continent than the former city.

Such being the case, I should be glad to know how Mr. Chambers would account for the following remarkable fact, viz., that the mean annual barometric pressures at St. Petersburg from 1822 to 1871 show a well-defined relation to the sun-spots *precisely the reverse* of that evinced by the figures for Bombay.

I might, if I had followed Mr. Chambers's example, have concluded, with as good grounds for my opinion, that "the sun is coldest when most spotted," and *vice versa*, but I prefer to wait until more extensive investigations have given us a sounder basis for induction than at present exists. Meanwhile, I place before your readers the figures on which my statement regarding the St. Petersburg pressures is based. The employment of a variety of methods of comparison has invariably given the same results.

In the following table the variations from the mean, expressed in millimetres, are compared with the sun-spots according to the plan recommended by Mr. Meldrum, and which for some purposes is superior to those generally adopted hitherto. For brevity's sake only the final columns are given :—

Mean Cycles

	Max. years in 5th line.		Min. years in 7th line.	
	Pressure variation in mm. (1822–71).	Sun-spots (1821–77).	Pressure variation in mm. (1822–71).	Sun-spots (1816–72).
1.	−0·52	−33·9	+0·15	+23·3
2.	−0·35	−23·4	+0·59	+14·5
3.	−0·48	0·0	+0·78	+ 4·8
4.	−0·24	+28·2	+0·63	− 5·6
5.	+0·44	+43·1	+0·29	−19·0
6.	+0·70	+34·2	−0·31	−32·5
7.	+0·80	+16·8	−0·83	−37·1
8.	+0·62	+ 0·2	−0·71	−25·4
9.	+0·34	−14·2	−0·40	+ 1·8
10.	−0·07	−24·2	−0·14	+30·9
11.	−0·88	−26·3	+0·23	+44·8

It will be noticed that the pressure epochs lag behind the sun-spot epochs in the same way as the air-temperature epochs determined by Dr. Köppen.

The figures for the pressure are taken from the Annals of the Central Observatory. The above relation was first brought to my notice by my friend, Mr. S. A. Hill, of Allahabad.

Mr. Chambers's notion that "if the winter rainfall of Northern India is really due to the cold of winter, we should expect it to be greatest when the sun is coldest" is partly

answered by the fact that, according to Mr. Hill, the epochs of heaviest winter rain are approximately those of *highest* mean annual temperature. E. DOUGLAS ARCHIBALD

Distribution of the Black Rat

MR. MIDDLETON'S letter in NATURE, vol. xix. p. 460, induced me to inquire whether the black rat still occurs in Dresden, the museum under my care possessing several specimens, which were procured on the spot several years ago. The streets where this rat then occurred being known to me, viz., Meissener-strasse, Alaun-gasse, Königsbrücker-strasse, all on the right bank of the Elbe, in Dresden-Neustadt, I inquired in many houses, offering a relatively high reward for a specimen, but hitherto in vain. The museum possessing further a specimen from a place called the Schenkhübel, about an hour's walk from the town, in the direction of the last of the above-named streets, I had traps put there, but also in vain; only the brown rat, *Mus decumanus*, could be procured.

Every two years a general rat poisoning being ordered by the magistrate of the town, I shall wait till the next one (March, 1880), and then try to state whether *Mus rattus* still lives in Dresden, as it no doubt lived here several years ago.

The museum possesses besides specimens from Mühlhausen, in Thuringia, and a series from Saxe-Altenburg; in the latter country I do not know the exact locality, the man—a dealer—who sent them, being very mysterious on this point, but I have indubitable evidence that it still lives there, and even is not rare on some spots. Knowing that it occurred some time ago in the brewery of Blankenhain Castle, near Crimmitzschau, in Saxony, I inquired there, but got the answer that for two years it has been replaced by *M. decumanus.*

Therefore, I am not sure that *M. rattus* still lives in the kingdom of Saxony, but I *am* sure that it occurs in the Saxon Duchies. I shall publish the results of my further inquiries in case they are successful.

From the Malay Archipelago I brought *M. decumanus*, but not *M. rattus*. I got specimens from North and South Celebes, besides other localities, but as the *Mures* in my collections are not yet definitely determined, I cannot give more particulars now. A. B. MEYER

Royal Zoological Museum, Dresden, May 3

Mice and Beetles

PERMIT me to ask, through the medium of your columns, if it is known whether mice kill the common kitchen black-beetle. I have been unable to find anything bearing upon this subject, but having observed that there is an apparent reduction in the number of beetles, or at least no increase in number while the mice are permitted to live, and also that the mice do not touch any articles of food in the kitchen, where they are somewhat numerous, I have been led to think that they prey on the beetles in some way. W. WORBY BEAUMONT

The Cause of Thunder

I HAVE lately seen it stated in a text-book upon electricity and magnetism that the phenomenon of thunder is not fully accounted for by any theory as yet brought forward. Whether this be so or not I am not sufficiently acquainted with the subject to say. I believe the commonly accepted theory is that a vacuum is created in the path of the electric spark and that the subsequent in-rush of the air produces the detonation. If, however, it be allowed that the electric spark is not a material substance, but merely a natural force or mode of motion, the possibility of this theory is at once disposed of.

It is a well-known fact that the passage of electricity in a high state of tension, through a mixture of oxygen and hydrogen, not only causes an explosion, but also causes the formation of water, and it seems to me that, given the existence of free oxygen and hydrogen in the region of the electric disturbance, the phenomenon of thunder is sufficiently accounted for.

Whether the normal amount of hydrogen in the air is sufficient to cause the stupendous noise of thunder I am not competent to judge, but if not I would suggest that the presence of an abnormal amount might be accounted for by the process of the electrolysis, which would probably occur between the two poles of the thunder-cloud before the tension became so great as to cause a rupture of the circuit and consequent discharge of the electric spark. I would also draw your attention to the fact that every thunder-clap is immediately followed by an increase in the quantity of water deposited in the shape of rain. Does not this point to the formation of water by the explosion of the gases?

As I myself am unable both from want of means and time to investigate the matter, I should be glad to find that someone better qualified had taken the subject in hand. It is a frequent experiment of Dr. Tyndall's to show his audience real clouds; I feel convinced that by following this line of inquiry he could give us a real thunderstorm. S. A. R.

The April Meteors

ON the night of the 20th these meteors were watched for between 10h. 45m. and 11h. 30m., after which the stars were obscured by a dense fog. During the ¾h. of observation 15 shooting-stars were counted, of which 4 or 5 only belonged to the shower of *Lyrids*. These were faint and somewhat slow, with slight trains and short paths. The radiant point could not be exactly fixed. Of the other meteors three were brilliant (2 = 1st mag. and 1 = 2nd mag.), and moved with extreme swiftness from a radiant point at $286° + 23°$. They left bright greenish streaks, and were readily distinguished from the *Lyrids*, though the radiants lie near together. This new shower near β Cygni (Albireo) appears to form an important display at this epoch. I saw several bright, rapid meteors from it on April 20–21 last year, and determined the position of its radiant point from a number of shooting-star paths given in Dr. Weiss's two volumes of Austrian observations at $288° + 22°$ (20 meteors) for the period April 19–23 (see *Monthly Notices* R.A.S., vol. xxxviii. p. 396). It is further confirmed by a stationary meteor recorded by Palisa at Troppau on April 19, 1870, at $289°{\cdot}4 + 26°{\cdot}4$, and it will be advisable to look out specially for this prominent shower of swift, streak-leaving meteors during future returns of the *Lyrids*. The latter display has quite failed during the last few years. W. F. DENNING

Ashleydown, Bristol, April 22

Salmo salar and the Schoodic Salmon

UNDER date of March 13, in the course of remarks on a late report of the U.S. Commissioner of Fish and Fisheries, you express a wish for an explanation of the fact that a sea-going salmon (*Salmo salar*) was found among the Schoodic "land-locked" salmon. I take pleasure in supplying the explanation. The fish referred to were taken in Grand Lake Stream, which connects two of the Schoodic lakes, tributary to the St. Croix River, which discharges into an arm of the sea on the border between the United States and Canada. Before the obstruction of the St. Croix by mill-dams, there was nothing to prevent the ascent of the sea-going salmon to this stream, and it is among the traditions of the aborigines that they were formerly often taken here along with the small "land-locked" or fresh-water salmon. The sea-salmon they called Pl-láhm; the land-locked, Tag-e-wáh-nàhn; and though for many years the sea-salmon were almost wholly prevented from ascending the river by the mill-dams, they have not been entirely exterminated, and the upper waters have been rendered in a degree accessible to the remnant by means of fish-ways constructed within a few years.

The specimen taken was, at the close of the season, set free with the other captured fish, and doubtless returned to sea.

I will add that the latest studies of American ichthyologists on the subject have led to the conclusion that the Schoodic and other "land-locked" salmon are specifically identical with *Salmo salar* (*vide* Jordan, "Manual of the Vertebrates of the Northern United States," 1878, p. 357).

Grand Lake Stream, Maine, U.S.A., April 9 — CHAS. G. ATKINS, Asst. to the U.S. Commissioner, Fish and Fisheries

Intellect in Brutes

A FEW months ago I made the acquaintance of a dog, which, I think, is worthy of a place among the dogs, and cats, and rats, and mules that are helping the pages of NATURE to determine the degree and kind of animal intelligence.

"Priest's" is a hotel on the way from the Calaveras Grove of Big-trees to the Yosemite. In former years, on the arrival of the stage, the landlady would send the dog to the poultry yard to catch chickens for the tourists' dinner. Now the dog "takes time by the forelock." The stage is due at six o'clock. About

five o'clock the dog saunters leisurely down the road till he meets the stage, he then bounds back to the poultry-yard, catches chickens, bites their heads off, and takes them to the cook! The number of chickens he kills bears a relation to the number of passengers he saw in the stage.

A gentleman who was stopping at the hotel for a few days went into the woods one afternoon with a gun. When he returned the dog came to him in much excitement to see what game he had taken. Finding his hands and his bag empty the dog ran into the forest and returned in less than an hour with a bird, which he gave with an air of compassion to the unskilful hunter. W. D. GUNNING

Waltham, Mass., April 18

ON THE EVOLUTION OF THE VERTEBRATA[1]

SEVERAL theories of the vertebrate skeleton have been promulgated during the last century, some of which have since been abandoned, and others greatly modified. About a quarter of a century ago, three great stumbling blocks were removed from the study of animal forms, by the discovery that the cell-wall was not essential as inclosing sarcode, by the removal of the old conceptions about the origin of species, and by the rejection of the vertebrate theory of the skull in its older and grosser form. In the present course, the lecturer wishes to give both an analytic and synthetic account of the vertebrate skeleton, to see if a consistent history cannot be given of every cartilage, bone, and joint, in the higher types.

A vertebrated animal is constructed of a chain of segments similar to each other, which are obsolete in the head, and in each of which there is a smaller dorsal tube, through which the continuous neural axis runs, and a larger ventral tube, which contains the digestive organs, heart, and main blood vessels. The neural axis swells into three main vesicles in the head, giving rise to the fore, mid, and hind brain. The skeletal structures are formed on a single median axis, the notochord, which lies directly beneath the neural axis, and which is arrested in the head close behind the fore-brain. The barrier, however, which would stop the growth forwards of the notochord, is not developed when its apex shrinks. By the time the embryo is fairly formed, a fold of the palatal skin has given rise to a sac which opens into the lower and hinder part of the fore-brain. This sac is the pituitary body, the manner of the development of which has been clearly made out by Mr. Balfour, in the sharks and skates, and corroborated by the lecturer in the snake, lizard, and green turtle.

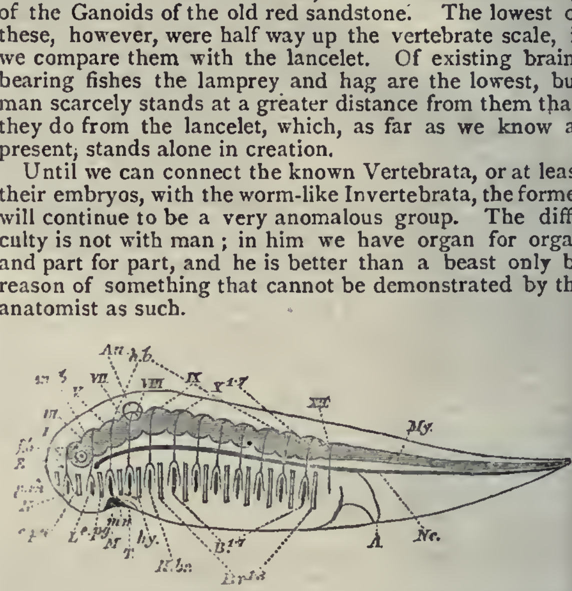
The mouth and posterior aperture do not exist at first, but are formed afterwards as involutions, which, in the latter case, at any rate, are not terminal, the alimentary tract extending behind the anus, and possibly in front of the mouth also in ancient forms. The visceral clefts appear as slits in the wall of the pharynx, and in the aquatic forms, give rise to the gills, while in the higher types (amniota), all of them close up but one, which remains as the tympano-eustachian cavity. The vertebræ alternate with the primary segmental masses. Each centrum, as it chondrifies, constricts the notochord, but there is usually some remnant of it to be seen in the adult in the invertebral spaces. The walls of the head are large and continuous, and its lower arches are generally small, clefts appearing between them. Both the arches and clefts become greatly modified in the adult, especially in the higher types. Thus the upper jaw is probably due to the modification and blending together of two or three pairs of arrested arches.

Besides the axial skeleton, a cartilaginous skeleton is developed immediately under the skin, and thus there is both a cartilaginous exo- and endoskeleton. The exoskeleton gives rise to the labial and extra-branchial cartilages, the limb arches and their limbs, and the intercalary cartilages of the median fins of fishes.

[1] Abstract of Prof. Parker's Hunterian Lectures, delivered at the College of Surgeons, commencing on February 10.

The bony parts of the skeleton are classified according to their relation to the axial or extra-axial cartilaginous skeletons. All bony scales, scutes, or sub-cutaneous bony plates, or tracts, are classified as exoskeletal; ossifications of the endoskeletal cartilage or its perichondrium are, of course, endoskeletal. Unfortunately for science, the extinct lower forms of the Vertebrata had their endoskeletons but slightly ossified, and thus only the outworks of their structure are left to us, as is the case with many of the Ganoids of the old red sandstone. The lowest of these, however, were half way up the vertebrate scale, if we compare them with the lancelet. Of existing brain-bearing fishes the lamprey and hag are the lowest, but man scarcely stands at a greater distance from them than they do from the lancelet, which, as far as we know at present, stands alone in creation.

Until we can connect the known Vertebrata, or at least their embryos, with the worm-like Invertebrata, the former will continue to be a very anomalous group. The difficulty is not with man; in him we have organ for organ and part for part, and he is better than a beast only by reason of something that cannot be demonstrated by the anatomist as such.



A, anus; *Au*, auditory capsule; B^{1-7}, branchial clefts; Br^{1-8}, branchial arches; *E*, eye; *e.pa*, ethmo-palatine; *e.pg*, epi-pterygoid; *f.b*, fore-brain; *h.b*, hind brain; *H.br*, hyo-branchial cleft; *hy*, hyoid arch *L*, lacrymal cleft; *M*, mouth; *m.b*, mid-brain; *mn*, mandible; *My*, myelon; *N*, nostril; *Nc*, notochord; *p.rh*, pro-rhinal; *T*, tympanic cleft. The Roman figures indicate the nerves.

The above diagram represents an ideal vertebrate, the oral, lacrymal, and nasal clefts being taken as homologous with the post-oral clefts. This theory seems probable both from the author's researches on the visceral arches and clefts, and those of Milnes Marshall on the nerves. The seven branches of the vagus (x^{1-7}) are here shown as separate nerves, and the hind brain as a series of enlargements.

As the relation of the endoskeleton to the exoskeleton does not usually seem to be properly understood, it may be as well to say a few more words about it. On the whole the foundations of the internal skeleton are laid in cartilage, and of the external in bone, which is formed by the ossification of fibrous tracts. The cartilage as a rule also ossifies, and this inner or *cartilage* bone has, so to speak, an organic affinity for the outer or *membrane* bone. But there are several things in the vertebrate exoskeleton that are formed of cartilage, as already mentioned; and in the endoskeleton the cartilage is often suppressed in certain parts, bony substance, formed in fibrous tissue, replacing it. Indeed, unossified fibrous tracts often take the place of cartilage. The welding together of parts originally distinct makes the matter much more complicated. No inherited elements are rejected by the morphological force; they are only kept from growing into special tissues until needed. Thus the rich growth of the human brain is covered in with a stout masonry that is merely made up of the inner layer of old ganoid plates, and the cartilages of the human nostril are inheritated from some ancient sucking fish, while the outer ear once figured, speaking morphologically, as the blow-hole of some Silurian shark.

A word or two must now be said about the different kinds of ossification. When the perichondrium, or clothing

of the cartilage, ossifies, it becomes the "ectosteal layer," and is directly related to the cartilage as its ossifying investment; this is a true endoskeletal lamina. Ossification of the dermis gives rise to "dermosteal" (exoskeletal) bony plates, such as the scales and scutes of fishes, and the scutes of reptiles and armadilloes. The intermediate fibrous tissue, especially in the region of the head, ossifies to form the splints, investing bones, or "parostoses" (exoskeletal). Lastly, the cartilage itself undergoes an osseous change, either by central, superficial, or subcentral "endostosis" (endoskeletal).

These species of ossification, like other species, are, however, apt to run into one another.

Fishes.—If we take a survey of the Vertebrata, beginning with the suctorial fishes, viz., the lamprey and hag, we find at first nothing but cartilage forming both the exo- and endoskeleton. The main peculiarities seen in the skeletons of these fishes are the peculiar cartilaginous labials, forming the sucking apparatus, and the basketwork of the "extra-branchials," which embrace the huge multiperforate pharynx. The Selachians (shark, skate, and Chimœra), although retaining much that is low and embryonic in their structure, are in many respects the highest and most reptilian of fishes. Their skeletal growths are uncombined; in their skin are numerous placoid grains or spines, forming the exoskeleton, while in the endoskeleton the first step towards ossification is seen in the calcification of the superficial cells of the cartilage. The labial system is now secondary, a more perfect mouth having taken the place of the sucking-apparatus. The basket-work of the sucking fishes yields bars to strengthen the mouths of the gill-pouches, the gill system being built upon large endoskeletal branchial arches. Limb-girdles, with their paired fins, appear in these fishes.

In the Chondrostei (sturgeon and paddle-fish (*Planirostra*), which are lower kinds of Ganoids, the slightly ossified cartilaginous endoskeleton is supplemented by outer bony plates, which, in the extinct forms, were often covered with an enameled layer. In the head, especially, these plates are conformed to the underlying parts, although they do not combine with them histologically. In this region they have also a constant tendency to a peculiar alternation of paired and unpaired elements. The scutes of the trunk, although suggesting the segments within, do not actually correspond with them.

Here we must look for the exemplars of our own investing-bones (*parostoses*) which are as yet, however, very generalized. The chondroskeleton now gets true ectosteal plates and sheaths, as well as parostoses.

But in those Ganoids that are called Holostei, the endoskeleton rivals that of the ordinary fishes in hardness, and yet the exoskeleton arrives at its highest pitch of perfection. In the head, the dermoskeleton is brought into adaptation to the more important architecture of the inner parts. The most perfect dermoskeleton is seen in the gar-pike (Lepidosteus).

The Dipnoi, which are in many respects related to the generalized chimœroids, show even less mutual adaptation of the outer to the inner skeleton than the sturgeon and paddle-fish, and, moreover, their bony skull plates are, as a rule, feeble, and few in number.

Lepidosiren and Protopterus have a few subcutaneous bones (parostoses) applied to a cranium which is almost entirely devoid of intrinsic ossifications, and scarcely advanced in development beyond that of a Chimœra. But Ceratodus has a helmeted head much like that of the lower Ganoids, the dermal scutes overlying the almost unossified cranium; it has also some sub-cutaneous bones.

The osseous fishes are the highest *as fishes*, but they are least of all related to those types which rise above them in the scale. Their metamorphosis is very great, but the elements are still uncombined. They have a copious growth of sub-cutaneous *bones*, as the Selachians have of sub-cutaneous *cartilages*, while in Ceratodus both are seen in an uncombined condition.

Amphibia.—The Amphibia are a subdivision of the Icthyopsida, which, like the Dipnoi, develop lungs as well as gills, but which often shed the latter, breathing only by the former. Their embryos, like those of fishes, develop neither amnion nor allantois. There are four orders in this sub-class, viz., the Cœcilians, the Urodeles, the Anura, and the Labyrinthodonts, the last of these being the large extinct Amphibia of the coal-measures. The living forms of Amphibia begin life as a sort of fishes, having gills; and, as a rule, they live in the water until they acquire lungs: some keep their gills, and continue to live in the water, while others shed them. The higher kinds undergo so much morphological change, and assume so many new and important characters, that they are perhaps the most instructive of all the Vertebrata.

In the Urodeles and Anura (tail-bearing and tail-less Amphibia) we find many things in common, and many more that are different. While they agree in possessing gills in their larval state, they differ in the character of their gills. The Urodeles have, some for a while, and others throughout life, three pairs of pinnate external gills, attached to the three first branchial arches, a single gill to each arch, there being generally a fourth arch which does not bear a gill. These are true *inner* branchial arches.

Amongst the frogs and toads there are three important modifications of the branchial system. In the common kinds (*Opisthoglossa*) there are at first free tufted gills growing from the two first, at least, of the four branchial arches, all of which are functional. These are soon hidden by an opercular outgrowth from the hyoid arch, which covers over and closes up all the branchial region, leaving, however, a small aperture on the left side. The primary pharyngeal wall not only splits so as to form four clefts on each side, but the wall itself becomes divided so as to form a series of pouches, each of which has a cartilage within and a cartilage without, the opercular skin loosely covering the pouches outside. The intra-branchial arches are small bars; the second and third extra-branchials are large bars, while the first and fourth are large pouches. Tufted vascular (*lophobranchiate*) growths, like those first seen outside, grow on the inside of the large pouches and bars, and also from the three branchial clefts, outside the extra-branchials. These latter correspond with the external gills seen in unhatched sharks and skate.

Dactylethra, one of the two existing *Aglossa*, shows no trace of external gills. The other, tongueless kind, *Pipa*, has probably very temporary rudiments of them. Suctorial cartilages have nearly disappeared in the embryos of Urodeles, but in the Batrachia they are nearly as much developed as in the lamprey. In the Urodeles we find no trace of a gill on the first and second arches behind the mouth, nor on the sixth, which exists in the majority of the species.

It is evident that the tailed Amphibia have been dropping from time to time parts no longer useful to them, whilst straining after a higher organisation. In them we have the beginning of the middle ear; there is a stapes and a fenestra ovalis. Here also a larynx appears for the first time, and the shoulder and hip girdles, and the fore and hind limbs are developed similarly to those of the higher types.

In neither Anura nor Urodeles is it possible to make a sharp distinction between a parostosis and an ectostosis, especially in the palate. The frogs and toads vary greatly in the intensity of their ossification; the parostoses pass into superficial dermal plates, and the bones, both superficial and deep, are apt to begin in a wild way, not keeping to the habitual landmarks. This is seen also to a less extent in Urodeles.

The mind of man is not able to invent a more wondrous

transformation than that which actually takes place in the life of every frog and toad. Born almost a lamprey, it changes into a creature which is a Selachian, and something more; for it passes through the further border of the sharks and skates, in their territory, and begins in its changing growth to make the rudiments, at least, of many an important organ which comes to its perfection in man and his nearest relatives. The growth force then fetching in improvements and additions from many a quarter, and combining all things skilfully, makes a new thing on the earth.

(To be continued.)

THE NEWEST EXPLOSIVE

GUN-COTTON and dynamite, which have for some years past held the foremost rank among modern explosives, are no longer, it seems, to retain this honour undisputed. A compound more violent still than either of these well-known preparations has lately been given to the world by M. Nobel in the shape of blasting-gelatine, and blasting-gelatine, again, has been endowed with still greater energy by a modification in its nature, effected by Prof. Abel, the War Department chemist. So far as experiment has shown, the gelatine and modified gelatine are, without doubt, the most active explosive agents known to us, or, in other words, a given weight of these compounds will work more destruction upon metal, stone, or other unyielding mass, than any of the hundred and one bodies of a like character with which we have become acquainted during the past half-century.

It is a well-known circumstance that, with but very few exceptions, the many explosives that have lately been brought before the public under a variety of names are merely modifications of one and the same thing. They are all nitro-compounds, or modifications of them. One class owe their origin to gun-cotton and the other to nitro-glycerine, and gun-cotton and nitro-glycerine are by the chemist regarded as the same thing. Gun-cotton is made by the nitrification of a solid body, and nitro-glycerine by the nitrification of a liquid body. The methods of manufacture are similar, and the agents employed to bring about the nitrification are the same. In the one instance a woody fibre—cellulose—is acted upon by a mixture of strong nitric acid and sulphuric acid, the former liquid to perform the operation of nitrification, by substituting certain equivalents of nitrogen for the hydrogen existing in the cellulose, and the latter acid for the purpose of absorbing any moisture given off in the substitution process, and thus preventing the nitric acid from becoming dilute and inefficient. In the other, a liquid—glycerine—is permitted to combine in small quantities at a time with a mixture of the same acids, and in like manner parts with its hydrogen, to be replaced by nitrogen.

There is, however, this wide difference in the application of the two compounds. Gun-cotton may be employed as it stands, and the Abel gun-cotton that is used by our soldiers and sailors for torpedoes and mining work is simply a pure pyroxilin, pulped fine to permit of its being thoroughly washed, and compressed into *papier-maché* sort of blocks, for the sake of convenience. Nitro-glycerine, on the other hand, being a liquid, is difficult to handle in that form, and for this reason it is that Nobel and others cast about for suitable vehicles to contain the preparation. A siliceous clay called Kieselguhr, which will absorb three times its weight of the liquid, has been found the most favourable substance, and dynamite, generally speaking, may be said to consist of 75 per cent. of nitro-glycerine and 25 per cent. of this inert substance. In lithofracteur, other substances besides, are employed, such as powdered charcoal and nitre, and there now exists a whole family of such combinations, none of which contain, however, more than 75 per cent. of the active explosive, nitro-glycerine.

In blasting gelatine, which, by the way, contains no gelatine at all, the objection to employing an inert material is got rid of altogether, and the mass, like compressed gun-cotton, is explosive and combustible throughout. Blasting, or explosive, gelatine is a mixture of nitro-glycerine and gun-cotton. M. Nobel, to whom is due the credit of having placed the valuable properties of nitro-glycerine at the disposal of mining-engineers, has discovered, in the pursuance of further investigations, that the liquid in question acts as a solvent upon gun-cotton. Like a mixture of alcohol and ether, nitro-glycerine is found to dissolve nitro-cellulose, and form a description of collodion, or, as M. Nobel terms it, gelatine. It is not, of course, the highly-explosive gun-cotton that will thus dissolve, but that known as photographer's pyroxilin, which does not contain so much nitrogen. Military gun-cotton, indeed, or tri-nitro-cellulose, to call it by its chemical name, should not be soluble at all, or at any rate only to a slight extent, if properly manufactured, and one of the tests to ascertain if it is of good quality is in fact to treat it with an alcohol-ether mixture to ascertain how far it will dissolve. The soluble gun-cotton, however, if not so highly nitrified, to coin a term for our purpose, is still a sufficiently explosive body, and this M. Nobel finds he can dissolve to a greater extent in nitro-glycerine than it is possible to do in alcohol and ether. Whereas the latter will dissolve no more than 4 or 5 per cent. of pyroxiline, and frequently less than 2, nitro-glycerine has been found to take up upwards of 7 per cent. The operation of dissolving is presumably done when the liquid is warm, and the result is, as we have said, a jellified mass, which has all the attributes of a definite combination. There is no separation of liquid from the mass, and cartridges may be made by simply rolling up the material in paper envelopes.

Thus, in blasting gelatine, there is no inert body, and the consequence is that weight for weight, the gelatine is superior in its destructive action to dynamite. The latter, as we have seen, contains 75 per cent. of nitro-glycerine, whereas blasting gelatine consists of from 90 to 93 per cent. of this liquid, and from 7 to 10 per cent. of soluble gun-cotton. But there exists another reason still, why the detonation of blasting gelatine should be more energetic, namely, because the combustion of the charge, from more perfect oxidation, is well nigh perfect. Prof. Abel pointed this out very clearly in his recent lecture at the Royal Institution. "As nitro-glycerine," he said, "contains a small amount of oxygen in excess of that required for the perfect oxidation of its carbon and hydrogen constituents, while the soluble gun-cotton is deficient in the requisite oxygen for its complete transformation into thoroughly oxidised products, the result of an incorporation of the latter in small proportions with nitro-glycerine, is the production of an explosive agent, which contains the proportion of oxygen requisite for the development of the *maximum* of chemical energy by the complete burning of the carbon and hydrogen; and hence," Prof. Abel concludes, "blasting gelatine should, theoretically, be even slightly more powerful as an explosive agent than pure nitro-glycerine."

By converting the gelatine into a more solid body by the addition to it of some 10 per cent. of military gun-cotton, or tri-nitro-cellulose, Mr. Abel appears to have secured a still more vigorous explosive, and one besides, that, by reason of its firmness, is more convenient to handle than the softer and pliant jelly. The destructive action of this modified gelatine upon iron plates and heavy masses of lead, has been found greater than that of any other form of nitro-glycerine or gun-cotton, and there is no room for doubt that for torpedoes and military mining, where the object is to secure the greatest degree of violence, regardless of consequences, the compound will find valuable application.

While on the subject of nitro-glycerine and its behaviour

as a detonating agent, a few words may be said upon the report of the Chief Inspector of Explosives that has just been issued by the Home Office. If only because it controverts a popular notion as to the dangers of this substance in a frozen state, the report in question is of considerable interest. Ever since the disastrous accident at Newcastle-upon-Tyne, when Mr. Mawson, the mayor of the city and several others lost their lives through the explosion of some packages supposed to have contained frozen nitro-glycerine, a wholesome dread of this substance has been entertained. But, strange to say, Major Majendie and Mr. E. O. Brown, of Woolwich, who appears to have been associated with the Chief Inspector in these experiments with frozen nitro-glycerine, found the latter far less sensitive either to blows or to fulminate powder than when in its ordinary condition. In some cases the frozen material allowed itself to be scattered by the violence used, without detonating at all, and it was only by using a very large charge of fulminate powder that its explosion succeeded. Frozen dynamite was still more obstinate, and under some circumstances, indeed, its detonation appeared almost impossible. Another circumstance of an unexpected character presented itself in these experiments. Mr. Brown found that the solidification of nitro-glycerine—a phenomenon that usually happens very readily some degrees above the freezing-point of water—is particularly difficult to bring about when the liquid is in a pure state. Continued subjection of the pure liquid to a temperature below freezing-point failed altogether to effect its solidification, and it was only upon the addition of a few grains of a solid body that the desired result was secured. The reason, therefore, why commercial nitro-glycerine so readily solidifies at a comparatively high temperature is obviously because it is not perfectly pure. H. BADEN PRITCHARD

THE BRITISH MUSEUM LIBRARY

IN NATURE, vol. xix. p. 253, attention was drawn to the state of the literature of science as available for reference in the library of the British Museum. The publications of scientific societies, home, colonial, and foreign, and those of the scientific departments of different governments, were especially mentioned both as defective in regard to completeness of series, and as difficult to find in the catalogue.

Pending steps being taken to secure some approximation to completeness of series, which must take time, it may be useful to offer some suggestions with regard to the cataloguing, a modification in which would save much time to readers. Any fundamental alteration would no doubt be undesirable, for from a librarian's point of view, the cataloguing at the British Museum has been so often pronounced excellent. There is, however, also the worker's point of view, and if the catalogue is not one which, after years of experience he can easily use, it is not to be accounted as perfect.

The simplest solution of the present difficulty would be to have printed a separate list, such as the Patent Office periodically prints, "a list of the scientific and other periodicals and transactions of learned societies in the free library." Should there be, however, a financial difficulty in the way of carrying this out, it would be a saving of time to readers if these transactions, proceedings, &c., of societies were entered in some distinctive way, such as by a coloured ink, or even by a stroke in the margin, so that they might be easily picked out from bye-laws, lists of members, reprints of separate papers, &c. Several of the older societies occupy many pages in the special catalogue "academies." It is the publication of the societies containing the papers that are, of course, most frequently wanted, but these are so mixed up with other entries, that it takes time to find their press mark. Further than that, different series, when such exist, have different press marks, and it is not every one who has a date and a volume number for reference that knows whether there is more than one series, so a wrong press-mark may be given. In some cases there are two or three sets, more or less incomplete, of a series of publications, some, perhaps, in the King's library, some in the Granville, some in the general library, &c. This is very confusing, as it is only in a few cases that any note is made of the extent of incompleteness, and if the wrong set should be written for, it involves the loss of at least half an hour, and on busy days probably an hour.

If all the serial publications of a society were given at the head of the entries of that society, or even if only marked in the margin as just suggested, it would save a reader much time in finding the press mark, and would also save still further time often by giving the press mark for the part of the series which contains the volume wanted.

There is another point which is worth consideration, and that is whether those who are known to use the library for purposes of research could not be in some way put on a different footing from those who go simply to read. It would not be an innovation, but only an extension of a principle already recognised. For example, if a reader wishes to consult certain MSS., he is taken into a separate room, if he wishes to consult some of the older or rarer books, there is another room for such purpose, and there is but little time wasted in bringing him what he wants. Students are admitted to the natural history collections on days when they are closed to the public. There are a large number of people who use the museum for other purposes than work. They write their letters, read their magazines and newspapers, go round among their friends and gossip, write a ticket for some interesting book of travel or a novel, and read bits of it in the interval of receiving visits. Not a few appear to go there for a rest. The objection to all this is that these people occupy seats, and it is becoming more and more difficult for a reader with many books out at once for consultation or search to find table space. It is a very trying thing for a writer with references to verify or to follow up, to see while he is waiting for his books that the time of attendants is occupied in fetching novels that can be bought at any railway book-stall, or pieces of music that can be obtained for a few pence. (It may be mentioned in passing that for the cataloguing of comic songs and dance music, the British Museum is unsurpassed in excellence.) It must require a strong sense of the immorality of making quotations or references second-hand, to give a man patience under the circumstances. If the works are wanted for reading there is of course no help but waiting.

Surely there might be some distinction made between those who go to the reading-room for systematic work, and those who go for amusement. The British Museum reading-room is something more than a library for Londoners; people come up to town on purpose to consult it. It is a national library. An average mechanics' Institute would supply the wants of many who now use the Museum, occupy seats there, and take up the time of attendants. There are other free libraries in London besides the British Museum.

If it is not found practicable to make a distinction for workers generally it might be worth while to try how it would do to have tickets of a special colour for "Academies" and that these should not be obliged to wait their turn with tickets for novels. There are already white and coloured slips in use.

It would be a great advantage if the publications of societies and scientific departments of governments were kept all together and placed directly under the care of an officer who should see to their being kept up in completeness.

ON THE FIGURE OF THE EARTH

THE columns of NATURE recently contained an interesting series of articles on this subject, with notes. One of these notes, which I here repeat, has a

peculiar interest. The author says: "The theory was next propounded that the earth was an ellipsoid of three axes, but the proposition was not fully supported by the evidence." Upon this Col. Clarke remarks: "This is scarcely correct; the figure of three unequal axes agrees better with the observations than does the spheroid of revolution. But there is a necessity for this, and the ellipsoidal figure cannot be regarded as established."

I venture to think that this note ought to be printed in capital letters. It condenses, especially in the words, "but there is a necessity for this," the following important paragraph in the preamble to Col. Clarke's well-known paper in the *Memoirs* of the Royal Astronomical Society, 1861:—

"Whatever the real figure of the earth may be, if in the investigation we suppose it an ellipsoid, it is quite clear that the arithmetical process must bring it out an ellipsoid of some kind or other, which ellipsoid will agree better with all the observed latitudes, as a whole, than any spheroid of revolution will. Nevertheless it would scarcely, I conceive, be correct to say we had *proved* the earth not to be a solid of revolution. To prove this would require data which we are not in possession of at present, which must include several arcs of longitude. In the meantime it is interesting to ascertain what ellipsoid does actually best represent the existing measurements."

It may seem superfluous, so far as the main point is concerned, to add anything to these quotations: but of the three which have been given, I have very little doubt that the first was by way of a protest against the fallacy which, in spite of the last, has gained such a remarkable currency. Am I mistaken in thinking that it *is* a too-prevalent opinion that the equatorial section has been *shown* to be elliptical? It may be so; but I conceive it to be so noxious an error, when it does exist, that it is better to give too much than too little currency to every authoritative corrective of such an error.

It is very much to be regretted when investigations which are essentially *tentative*, and which are carefully guarded as such by sentences which are to be found if looked for, obtain through no fault of their own the character of demonstrations. I think Col. Clarke has run the risk of giving to the above fallacy a stronger hold by neglecting to emphasise with sufficient force, in his more recent calculations, their true character; and perhaps still more by seeming to entertain something of an expectation that the arithmetical result will be substantiated by increased data. Writing of the later result—as to which we may properly note that the equatorial major axis occupies a position differing from that of the former by 24° of longitude—he says: "But too much confidence must not be placed in it: as yet it is merely indicated by the existing observations, and the amount of the eccentricity of the equator shown is really very minute."

I am unwilling to seem to differ from so high an authority, especially on a point which I wish to have "reserved:" I therefore refrain from inquiring whether any such expectation is really entertained, preferring to adduce some arguments which tell the other way.

Whatever the real figure of the earth may be, it is as certain that, if we knew it exactly in every part—instead of only very uncertainly in a very few—a triaxial ellipsoid could be found which would fit it better than any other triaxial ellipsoid, as it is that a biaxial ellipsoid could be found which would fit a given egg better than any other biaxial ellipsoid. But we happen to know that eggs are generally egg-shaped, and not elliptical. So also we know—I hope it is not necessary to stop to prove this—that the earth is earth-shaped, and not ellipsoidal. If the best possible ellipsoid were fitted to it, the two would disagree everywhere more or less. It is not, therefore, as regards the present argument, a question of more data. If the figure were conformable to any ellipsoid, the existing data would suffice. Their insufficiency proves the non-conformity, and additional data cannot disprove it.

What additional data may be *expected* to do is to modify the approximate ellipsoid until the ellipticity of its equator disappears—in other words, until it becomes an elliptic spheroid.

Can I give any ground for this expectation? It would be fair to ask in return, Can any ground be shown for expecting a body, believed to have acquired its spheroidal form by rotation, to have an equator not circular? I will answer the latter inquiry first, myself. The same, or similar, causes which distributed land and sea irregularly have probably produced an equator which is not circular. But I know nothing to lead me to expect that the form of the equator has any better claim to be considered elliptical than circular, than this—an ellipse can generally be found which will fit an irregular area better than a circle. This argument can be turned against me, but only by admitting the irregularity. If the irregularity is admitted, I concede *an* elliptic equator for the approximate or mean figure. And the question is now reduced to one of degree.

The difference of equatorial semi-axes in Clarke's earlier investigations was 5,308 feet (1861), and subsequently 6,378 (1866). It is now 1,524 feet.

We are here, to go no further, within the limit of inequality assignable to the larger disturbances of sea-level; that is to say, to one kind only, of local irregularity.

In short, while I recognise with the most unreserved respect and admiration the labours which have resulted from the first attempt to ascertain whether a tri-axial ellipsoid was sufficiently indicated to be probable, I presume to think that Colonel Clarke's words of caution demand the utmost attention, and that the results at which he has arrived should be construed rather as disproving than as proving the reality of a sensibly elliptic equator.

I should extend this article too far if I did more than indicate one other ground for caution in describing the figure of the earth. Our knowledge on that head, as derived from arc-measures, is deceptive in proportion as we lose sight of the significance of the fundamental assumption that the figure is a regular one. Gross assumptions which suit an early stage of an inquiry may have to be abandoned later. The forms of the surfaces whose curvatures arc-measurements determine, are in any case local and particular; and so soon as local character appears, further consideration of the assumption is demanded. This, no doubt, is the reasoning out of which the tri-axial ellipsoid grew. It must not stop there. The tri-axial ellipsoid is not the only next step. Forced by the rigour of observation to abandon the elliptic spheroid as a final definition, and to admit irregularities as coming now within the range of more particular inquiry, the problem has in effect changed its face. To cling to the old assumption is to delay the recognition of the new phase. To look for additional data as means of substantiating or modifying an empirical modification of it is to halt in the presence of the larger problem which is opening before us.

Will it not be wiser to change the mode of attack? To bestow increased attention on the causes of irregularities and the probable magnitude of their effects? To theorise and calculate in this direction, on the one hand, and to extend experiment on the other, where such reasoning shall point the way? If we do this, the ultimate inadequacy of arc-measurements must receive recognition. The most obvious of all the causes of irregularity—the fluidity of the ocean and its obedience to the attraction of the land masses, must, one would think, invalidate their evidence materially. If, further, we consider the

actual conformations of the great terrestrial divisions of land and sea, arcs of longitude are, I imagine, especially likely to be affected by such causes.

The views which I have now attempted to express are by no means new, but it has not appeared necessary to cite authorities. I am indebted to many writers, but I should be sorry to have to assign to each the measure of the influence which his learning has had on the drawing up of this brief, which I hope some geodesist will now take up and argue more fully and more ably.

Dehra J. HERSCHEL

THE ROYAL SOCIETY SOIRÉE

ON Wednesday last week the President of the Royal Society gave a *soirée* at Burlington House, which was largely attended, and at which a considerable variety of apparatus were exhibited and many experiments made. Mr. Crookes showed his exhausted tubes and other apparatus, illustrating various phenomena connected with molecular physics in high vacua. The experiments made by these were the following:—

1. *Dark Space round the Negative Pole.*—When the spark from an induction coil is passed through an ordinary vacuum tube, a dark space is seen round the negative pole. The shape and size of this dark space do not vary with the distance separating the poles; nor, only very slightly, with alteration of battery power, or with intensity of spark. This well-known dark space appears to be a layer of molecular disturbance identical with the invisible layer of molecular pressure or stress, the investigation of which has occupied the exhibitor some years.

2. *The Electrical Radiometer.*—An ordinary radiometer is furnished with aluminium cups for vanes. The fly is supported by a hard steel cup, and the needle point on which it works is connected with a platinum terminal sealed into the glass. At the top of the radiometer bulb a second terminal is sealed in; the radiometer can therefore be connected with an induction coil, the movable fly being made the negative pole. At low exhaustions a velvety violet halo forms over each side of the cup. On increasing the exhaustion the dark space widens out, retaining almost exactly the shape of the cup; the bright margin of the dark space becomes concentrated at the concave side of the cup to a luminous focus, and widens out at the convex side. On further exhaustion, the dark space on the convex side touches the glass, when positive rotation takes place.

3. *Green Phosphorescent Light of Molecular Impact.*—At very high exhaustions the dark space becomes so large that it fills the tube, and when German glass is used the sides are beautifully illuminated with a greenish yellow phosphorescent light.

4. *Projection of Molecular Shadows.*—The rays exciting this green phosphoresence will not turn a corner in the slightest degree, but radiate from the negative pole in straight lines, casting strong and sharply-defined shadows from objects which happen to be in their path. The best and sharpest shadows are cast by flat disks, and not by narrow pointed poles; no green light is seen in the shadow itself, no matter how thin, or whatever may be the substance from which it is thrown.

5. *Magnetic Deflection of the Trajectory of Molecules.*—The stream of molecules, whose impact on the glass is accompanied by evolution of light, is very sensitive to magnetic influence, and the shadow can be deflected by bringing a small permament magnet near, the amount of deflection of the stream of molecules being in proportion to the magnetic power employed. The trajectory of the molecules forming the shadow is curved when under magnetic influence.

6. *Focus of Heat of Molecular Impact.*—Great heat is evolved when the concentrated focus of molecular rays from a nearly hemispherical aluminium cup is allowed to fall on a strip of platinum-foil, the heat sometimes exceeding the melting-point of platinum.

7. *Mechanical Action of Projected Molecules.*—An actual material blow is given by the impinging molecules. A small vaned wheel being used as an indicator, by appropriate means the molecular shadow of an aluminium plate is projected on the vanes. When entirely in the shadow the indicator does not move, but when the molecular stream is deflected so that one-half of the wheel is exposed to molecular impact it rotates with extreme velocity.

8. *Phosphorogenic Properties of the Molecular Stream.*—Substances known to be phosphorescent under ordinary circumstances shine with great splendour when subjected to the negative discharge in a high vacuum. (*a.*) *Becquerel's Luminous Sulphide of Calcium* shines with a bright blue-violet light, and when on a surface of several square inches, is sufficient to faintly light a room. (*b.*) *The Diamond* is very phophorescent. Most diamonds from South Africa phosphoresce with a blue light. Diamonds from other localities shine with different colours, such as bright blue, apricot, pale blue, red, yellowish green, orange, and pale green. One large fluorescent diamond gives almost as much light as a candle when phosphorescing in a good vacuum. (*c.*) *The Ruby* glows with a rich full red, and it is of little consequence what degree of colour the stone possesses naturally, the colour of the phosphorescence is nearly the same in all cases.

Besides these experiments the working of the writing telegraph, exhibited by Mr. E. A. Cowper, attracted much interest. The nature of this invention we described when it was first announced, and gave a specimen of the kind of writing produced. Other exhibits deserving notice were Prof. Guthrie's broken glass in frames, illustrating the fracture of colloids, Edison's loud-speaking telephone, Messrs. Preece and Stroh's synthetic curve machine, and frame of curves produced thereby; their automatic phonograph, electromagnetic vowel-sounder, stereoscopic curves, synthetic sounder and syren, and phonautograph. Apparatus and instruments of various kinds were also exhibited by Messrs. Browning, Hilger, and Tisley and Co. Among Mr. Hilger's exhibits was a quartz spectroscope for the ultra-violet rays, constructed for the Scientific Society of Stettin, under the direction of Dr. Schönn.

A NEW CALENDAR CLOCK

IT has always been a matter of surprise that the Americans can produce their well-known eight-day clocks in such large quantities, so uniformly good for ordinary purposes, and at such very moderate cost. Their general efficiency is proved by the increasing demand for them; not only are they sold in the American made cases, but separate movements are extensively imported and cased in England. One of the largest firms by which they are produced, that of Seth Thomas and Co., at Thomaston, Conn., has recently introduced a library or office clock of very moderate cost, one form of which is shown in the accompanying figure. This consists of the ordinary eight-day striking movement supplemented by an interesting and ingenious mechanism for operating the calendar; by its means not only the month and day of the week and month are indicated as in ordinary calendars, but the several months have their allotted number of days, an additional day being given to February in leap-year. Of course contrivances for effecting this object have long been known, but they always add so materially to the cost that they are prevented from coming into general use.

It would be impossible to fully explain the mechanism employed without the aid of drawings; a general description must therefore suffice. As will be seen, the calendar dial is placed below the clock dial, and is divided on its

circumference from 1 to 31. Two openings on a horizontal diameter allow drums to show the month and day of the week respectively, and a central hand points out the day of the month. A cam, formed like the snail of an English striking-clock, but without the steps, is caused to rotate once in twenty-four hours by the clock movement, so that a pendant, resting on it, is raised through a space of about 1 inch in that period and allowed to fall, the weight being supplemented by the tension of a spiral spring; this is the sole connection between the calendar and clock. During the ascent of the pendant a detent passes over one tooth of a wheel fixed to the week-day drum, which is thus carried round through a corresponding interval when the release occurs. At the same time a precisely similar action, performed on a wheel fixed to the axis that carries the hand, causes it to advance one figure.

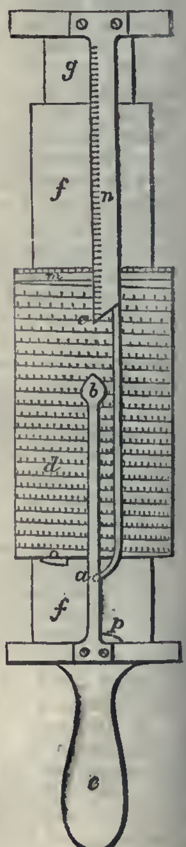
Just as the cam driven by the clock accomplishes the change from day to day, so a second cam on the central axis of the calendar alters the month; the detent, on being released, carries forward one tooth of a 12-toothed wheel. It remains to explain the device for allotting the requisite number of days to each month and correcting

8-day Parlour Calendar, No. 4. Height 25 inches. Spring-Strike. 8-inch Dials.

for leap year. The axis of the month drum carries an irregular shaped cam, which may be conceived to be divided radially into twelve parts. Those arcs of the circumference that correspond to 31-day months are left untouched; 30-day months have their arcs filed away to the corresponding chord; and for February a depression is made equal to three times that of other months such as April. A light spring holds a bent arm against this cam, the arm being so placed that at the end of each short month it can ride on a metallic arc carried round with the hand; the acting length of this arc corresponds to one or three teeth of the dial-wheel if the 30th or 28th is the last day, and the arm entirely escapes it when thirty-one days are to be indicated. Whenever it is thus held out of its natural position, the arm prevents the check-spring that limits the movement of the dial-wheel from falling into its place, and the detent is thus enabled to advance the hand through two or four spaces instead of the usual one. An additional day is given in leap-year by a simple application of the well-known sun and planet wheel of Watt. The central fixed wheel is coaxial with the month-drum and has sixteen teeth; the planet-wheel, pivoted on the cam, has twenty teeth, and carries a sector of such a radius that, when superposed on the February depression, it diminishes the fall of the arm so that it rides on an arc corresponding to two teeth instead of three. It will be seen that the above numbers of teeth are so chosen that the wheel carrying this sector is only brought into an identical position once in every four (annual) rotations of the month-drum; the necessary correction is therefore effected.

SPIRAL SLIDE RULE [1]

THE method of multiplying and dividing by means of a rule was first introduced by Gunter about the year 1606 by the construction of a scale of two equal parts divided logarithmically, the readings being taken off with a pair of compasses. Oughtred about 1630 invented the rule composed of two similar logarithmic scales sliding in contact, but the difficulty of estimating the reading between two graduations then first became important. It is easy to see that it requires but little practice to place a graduation in one scale opposite to a position obtained by estimate between two graduations in the other scale, but it becomes a much more tiresome and uncertain process when both of the readings required to be placed in juxtaposition fall between two graduations on their respective scales. With practice, however, this operation can be effected with considerable accuracy provided the graduations are not too close together; hence to enable the calculations to be performed with a sufficient degree of approximation there has always been a desire to increase the scale and consequently the total length of the instrument. To attain this object and at the same time preserve the portable size of the instrument Prof. Everett designed his slide rule, but the range of this is now far surpassed by the invention by Prof. Fuller of the spiral slide rule.



The instrument can be readily understood from the accompanying figure.

d is a cylinder that can be moved up and down or turned round on the cylinder *ff*, attached to and held by the handle *e*. Upon *d* is wound in a spiral a single logarithmic scale. Two other indices, *c* and *a*, whose distance apart is equal to the axial length of the spiral, are attached to the cylinder *g*, which slides in *f* and thus enables the operator to place them in any required position relative to *d*. *o* and *p* are two stops which when placed in contact bring the index *b* to the commencement of the scale. *m* and *n* are two scales, one attached to the movable indices and the other to the cylinder *d*.

By the spiral arrangement the length of the scale can be made very great, and as only one scale is required the effective length is double that of an ordinary straight rule. The scale is made 500 inches, or 41 feet 8 inches long, and the instrument is thus equivalent to a straight rule 83 feet 4 inches long or a circular rule 13 feet 3 inches in diameter. The first three digits of a number are printed on the rule throughout the scale, much increasing the facility of reading off. The method of using the different indices will be best understood by examples. For multiplication—bring 100 to the fixed index *b* and place the movable index to the multiplicand,

[1] By George Fuller, M.Inst.C.E., Professor of Engineering, Queen's University, Ireland.

then move the cylinder so that the multiplier is at the fixed index. The product is read off at one of the movable indices, bearing in mind that the number of figures in the product is the algebraic sum of the number of figures in the multiplier and multiplicand, if it is not read upon the same index as the latter, but it is one less than that sum if read upon the same index. The use of the scales *n* and *m* is shown by the following: *n* being read from the lowest line of the top spiral and *m* from the vertical edge of the former. To find the value of 5^{13}: on placing *c* to 500 scale *n* reads ·68, and scale *m* ·01897, which gives ·69897 for the logarithm of 5. ·69897 × 13 = 9·08661. Next placing the cylinder so that it reads ·08661 on scales *m* and *n* the index *c* reads 12207, hence the required power is 1220700000 consisting of ten figures as required by the logarithm above. Where a considerable degree of accuracy is required we believe this slide rule will be found of much service, but it cannot compete on the one hand, on account of its somewhat cumbrous nature, with the ordinary patterns of slide rule for rough and ready work, or on the other with a table of logarithms for calculations requiring close approximation.

OUR ASTRONOMICAL COLUMN

A NEW NEBULA.—Dr. Tempel, of the Observatory of Arcetri, Florence, notifies his discovery of a nebula on March 14 in a part of the heavens which has been most rigorously scrutinised in searching for these objects. For this reason it was at first supposed to be a faint comet, and was compared with the seventh magnitude following, W.B. XI. 305; but on March 16 its place was found to be unchanged. Dr. Tempel says it is properly a double nebula, with two small but distinct nuclei, distant from 15″ to 20″, and he adds the nebula Herschel II. 32, which is in the vicinity, was on both evenings much smaller and fainter than the new one. Herschel's nebula is caught at once in slow sweeping with a 6 or 7-inch refractor, so that an object to be very decidedly more conspicuous, must be within reach of ordinary telescopes, and it is hardly credible that its appearance can have long been as Dr. Tempel now describes it, without its being previously detected. Mr. Lassell's Catalogue of 600 new nebulæ discovered at Malta contains several in the immediate neighbourhood, so that the observer, Mr. Marth, could hardly have failed to have his attention called to the object in question, if then as visible as at present. Dr. Tempel's nebula is obviously worthy of immediate and continued observation; its position for 1879 is in R.A. 11h. 18m. 5s., N.P.D. 86° 1′·4, or it precedes the seventh magnitude above named 1m. 27s., nearly on the parallel. Chacornac, in his Chart No. 34, has a star 12·13 mag. within about 3′ from the above position, but shows no nebulosity; this circumstance is of itself sufficient proof that the nebula was not visible twenty-five years since. We would suggest that the position of this object relatively to the stars near it should be determined with all possible accuracy; it will be remembered that the centre of condensation in the variable nebula in Taurus has appeared to oscillate about the point where it was first remarked in October, 1852; or, to speak perhaps more correctly, nebulosity has at times been quite imperceptible in the original place, though apparent at a very short distance from it.

BRORSEN'S COMET.—In No. 2,254 of the *Astronomische Nachrichten* Dr. Armin Wittstein of Leipsic has given an orbit and ephemeris for this comet, founded upon a correction of the elements of Prof. Schulze by means of observations at Leipsic on March 19 and 26. There appears, however, to be error in the work; the new elements differing much from an observation on April 14, and so far as we can see, it is probable that the ephemeris for May, which has appeared in NATURE, will be much nearer the truth than Dr. Wittstein's figures; at the same time it is to be remarked that the predicted elements require sensible correction, though not to such an extent as his calculations would indicate. Were it considered worth while, an orbit might be deduced from the observations already made at the present appearance, which would afford the means of following the comet closely during the remainder of its visibility, but the predicted elements with a correction to the time of perihelion passage, will doubtless suffice for finding the comet readily, as long as it is within reach.

RE-OBSERVATION OF TEMPEL'S COMET, 1867 II.—In a communication to the Paris Academy it is announced that the comet of short period discovered by Dr. Tempel in 1867, and observed again at its return to perihelion in 1873 after experiencing heavy perturbation from the action of Jupiter, was found once more by its original discoverer, at the Arcetri Observatory on April 24. At 14h. 30m. Florence mean time, its R.A. was 16h. 50m. 59s. and its declination 13° 32′ south, so that its position corresponds nearly with that given in the first of M. Raoul Gautier's three ephemerides in *Astron. Nach.*, No. 2,242, in which the perihelion passage is assumed May 6·9416 Berlin M.T. Dr. Tempel says he had searched for it in vain during the rarely fine nights of February and March. The comet is faint and diffused, with a granulated appearance about the centre, and 2′ in diameter. This granular characteristic of comets, by the way, is one which has been frequently noted by Dr. Tempel, and which other observers do not appear to recognise so often. He directed particular attention to it when announcing his discovery of the comet of the November meteors, 1866 I.

If the perihelion passage of the comet 1867 II. be assumed to take place, 1879, May 6·9537 M.T. at Greenwich, and the mean diurnal motion = 593″·184, with the other predicted elements of M. Raoul Gautier, it is probable that the comet's position will be given very nearly during its present appearance. The co-ordinate constants in his orbit, for apparent equinox of June 1, are:—

$$x = r\,[9{\cdot}99389],\ \sin.\,(v + 328^\circ\ 2'{\cdot}4),$$
$$y = r\,[9{\cdot}95727],\ \sin.\,(v + 242\ 33{\cdot}4),$$
$$z = r\,[9{\cdot}65727],\ \sin.\,(v + 218\ 41{\cdot}7).$$

GEOGRAPHICAL NOTES

THE steamer *Nordenskjöld*, Capt. Sengstake, belonging to Herr A. Sibiriakoff, is almost ready to sail from Gothenburg for Behring Straits, *viâ* the Suez Canal, to search for the *Vega*, along with the *Jeanette*, belonging to Mr. Bennett, of the *New York Herald*. Herr Gregorieff, of the St. Petersburg Geographical Society, sails with the *Nordenskjöld*. Herr Sibiriakoff is sending off two coast searching parties to Behring Straits, one from Nischni Kolymsk and the other from the mouth of the Anadyr.

THE current number of the Royal Geographical Society's monthly periodical contains ample evidence of the good work which is being done by our missionaries towards making geography. Dr. James Stewart contributes an account of the second circumnavigation of Lake Nyassa, Dr. Laws a report of his journey along part of the west side of that lake, and Mr. G. Blencowe notes on the physical geography of Zululand and its borders, based on nineteen years' experience on the Natal and Transvaal frontiers. The geographical notes are fairly good, the more important being those which describe a new route from the Caspian to Kungrad, and recent explorations in Persia and Central Australia, but we cannot refrain from expressing our surprise that in a periodical, which ought to be the leading authority on geography, more space is not devoted to this department, the most important of all, for therein should be recorded brief accounts of all that is being done in the way of travel and exploration throughout the world. It will interest many of our readers to learn that the full text of

Prof. Geikie's able lecture on geographical evolution is promised for the June number.

We understand that, chiefly through the instrumentality of a veteran Arctic officer, the Council of the Royal Geographical Society were some time back induced to urge upon H.M. Government the propriety of despatching a vessel to the relief of Prof. Nordenskjöld early in the present season. The matter, of course, was referred to the Admiralty, and "My Lords," after mature deliberation, have arrived at the conclusion that the matter had better be left to private enterprise. This resolution may be looked upon as a tolerably sure indication that the present Government are not disposed to embark upon an Arctic expedition of any description.

We hear that Mr. Keith Johnston, the leader of the Geographical Society's East African Expedition, was to leave Zanzibar at the end of last month for Dar-es-Salaam, on the mainland, with the view of making final preparations for his journey to Lake Nyassa. The fact of his having been fortunate enough to secure the services of Chuma, Livingstone's old follower, will, no doubt, smooth away many difficulties, which otherwise would have caused him much trouble. Mr. Johnston has, we believe, turned his somewhat lengthy stay at Zanzibar to good account in the accumulation of all the information that could be procured respecting the tribes through which he will have to pass; and in this matter he has received very great assistance from an Arab named Bushire bin Selim, who is acquainted with some part of the country between the coast and Lake Nyassa, and who states that, though there is no direct road from the coast, the region at the north end of the lake is regularly visited by branch routes from the main road between Bagamoyo and Ujiji.

M. de Semellé, whose death was we are glad to say prematurely announced, has succeeded in ascending the Niger and the Binué as far as Okeri, a point, it is stated, which has not hitherto been explored. He has collected valuable information on the products of the country, and the history and traditions of the people. He intends meantime to return to France for further subsidies to enable him to continue his exploration. M. Soleillet, who had to return to St. Louis in Senegal, after reaching Segou, is to set out on a new expedition for "Tichid, Wallatana, Timbuctoo, the Touat, and Algiers." M. Soleillet has brought back much interesting information concerning the people among whom he has been travelling, and of whom he speaks in very high terms for their intelligence and culture.

M. Savorgnan de Brazza is about to set out for further exploration in the Ogowé region; he will endeavour to penetrate to the interior by the Alima and the river into which it falls.

In No. 4 of the *Mittheilungen* of the Vienna Geographical Society, Count Stefanovic von Vilovo discusses the causes of the recent disastrous floods at Szegedin. Five years ago, it seems, he prophesied that some such catastrophe must happen, but he was only laughed at. He showed that this would be caused by the damming back of the water in the narrow rocky passes at Plocsa, and in the Kazan, in the narrow pass between Bazian and the Iron Gates, the surplus water being thus forced back into the nearest tributaries, the Morava, the Temes, the Save, and above all the Theiss. He maintains that the present disasters are solely the work of those rocks at Plocsa and in the Kazan, preventing the carrying off of the unusual quantity of water thrown into the river by the rains and snows of last autumn. Dr. Holub's paper on the Marutse-Mambunda is continued, with many illustrations and vocabularies, as also the papers of Prof. Benoni, on the sources of the Dniester, and Hesse-Wartegg's, on the river-bed of the Mississippi. Herr von Hochstetter contributes an illustrated paper on the magic instruments of the rain-maker among the natives of Inner Australia.

A letter from Herr Déchy, dated Darjeeling, March 9, in the *Mittheilungen* of the Vienna Society, states that in a day or two he expected to leave with a well-equipped expedition for exploration in Western Sikkim. He was to go through the valley of the Great Runget to the south foot of Kinchingunga; thence, climbing the Pundim-Nursing ridge into the Testa Valley, he was to explore the valleys, mountains, and passes of the Thlonok and Zemu rivers. Herr Déchy expects to add much to our imperfect knowledge of these regions, and his expedition is well supplied with instruments for scientific observation.

The new number of *Les Annales de l'Extrême Orient*, which is doing good service by its translations of the accounts of Dutch explorations in Oceania, &c., contains remarks by H. von Rosenberg on the Schouten Islands at the entrance to Geelvink Bay, New Guinea, and brief notes by M. van Hasselt on Alahan-Pandjang in Sumatra, accompanied by a map. This periodical, it may be mentioned, records the proceedings of the Société Académique Indo-Chinoise.

We understand that Prof. P. J. Veth, of Leyden, the learned president of the Geographical Society of the Netherlands, has been elected an honorary corresponding member of the Royal Geographical Society.

We learn from the *Colonies and India* that a very interesting operation has been performed in the Thames River, New Zealand, viz., the blowing up of the Awotonga Falls, near the Awoka mountain. They were 75 miles from the mouth of the river, and had been a great hindrance to navigation. The falls were blown up with 200 lbs. of dynamite, the column of water rising to a height of 470 feet, and forming a magnificent spectacle. In addition to these falls, there have been removed in a similar manner several dangerous and impassable rapids and upwards of 500 "snags," varying from two to eight feet in diameter, and some of them 120 feet long. The clearing of this river, it is said, will open up a million acres of excellent land, which the Government have obtained from the natives.

TRENHAM REEKS

With much regret we record the death of Mr. Trenham Reeks, the esteemed Registrar of the Royal School of Mines, Jermyn Street. He had been ailing for some weeks, and last week the complaint assumed the serious form of inflammation of the lungs. There was still hope of his recovery a few days ago, but he expired on Tuesday morning, the 5th inst. By his death one of the oldest associations of the Geological Survey and School of Mines is severed. While still young he became connected with the infant museum established by the energy of his friend, Sir Henry de la Beche, in Craig's Court; and on the enlargement of that establishment and the creation of the School of Mines, he was appointed to the office which he has held up till now. Having in early life devoted himself to chemistry and mineralogy, he took great pride in the mineralogical collection under his charge in Jermyn Street, and from year to year enriched it with fresh acquisitions. He had a great knowledge of pottery, and gained it at a time when the taste was far less general than it is now. The illustrated hand-book which, in conjunction with De la Beche, he prepared of the ceramic collection in the Jermyn Street Museum, though long ago out of print, is still a valued work of reference. Personally, he was singularly courteous and obliging, though tenacious of purpose and not easily defeated in any matter wherein he had resolved to succeed. He thoroughly identified himself with the interests of the School of Mines, to which his loss must now be great.

Not a few who read these lines will long remember the

little, rather dingy, room in which, for well nigh thirty years, he has sat amidst blue-books, calendars, mineralogical specimens, and a rather orderly chaos of miscellaneous objects. They will think with sadness of the rupture of these old associations, and will follow to the grave with deep respect and sincere regret the old friend who has been so suddenly and unexpectedly removed from their midst.

WILLIAM GEORGE VALENTIN

IT is with much regret that we record the untimely and sudden death on the 1st inst. from apoplexy of Mr. William George Valentin. He was born in Neuenburg, in the Black Forest, on May 16, 1829. He came to England in 1855, and, in the early days of the Royal College of Chemistry, studied under Dr. Hofmann, who esteemed him greatly, and, recognising his ability, made him senior assistant in the laboratory, a position which he retained at the Science Schools, South Kensington, under Dr. Frankland. He held for some years the office of gas examiner to the Great Western Gas Company, and at the time of his death was chemical adviser to the Trinity House.

His chemical text-books are deservedly popular; and within the last few days he corrected the final proofs of a new work which is therefore nearly ready for publication.

Mr. Valentin was a successful and painstaking teacher, and the fact that so many of the well-known chemists of this generation have received their early training from him, sufficiently indicates the value of his work; it would be difficult, indeed, to find one to whom the younger chemists of the present day are more indebted.

Within the last few weeks a few of his old friends and students of the Royal School of Mines had intended to present him with a testimonial; the efforts of the committee formed for this purpose will now be continued for the benefit of his widow and family.

ELECTRIC LIGHTING

WE need not insist on the extreme importance and interest of the exhibition which was opened last night at the Albert Hall, and for which extensive preparations have been making for some time. The public mind both in this country and abroad has been recently much agitated on the question of electric lighting, and, as might be expected, people are much confused among the many systems which have been brought forward, and even those who know something of the subject must find it difficult to make up their minds. Hence the importance of bringing together the various systems of electric lighting in such a way as to make comparison possible. It must, moreover, have an important educational influence upon the general public, helping somewhat to give them a truer idea of what physical science is, and what it is capable of doing for the good of mankind. The exhibition was opened last night by an able and interesting lecture by Mr. W. H. Preece, the chair being occupied by the Prince of Wales.

The machines to be exhibited are not only those which have been recently attracting attention, but also older ones, which will exhibit in an impressive manner the history of the development of electric lighting. Thus there are in the arena of the Albert Hall specimens of Mr. Holmes's original magneto-electric machine, and of the Alliance Company's magneto-electric machine, lent by Trinity House, as well as the Siemens dynamo machine and the Gramme machine, now so much in use for generating electricity for lighting and other purposes. There are also varieties of the Gramme and Siemens machines, differing from each other more in minute detail than in general principle.

The Jablochkoff and the Lontin systems are also strongly represented. From the centre of the dome depend five large lamps of the Siemens pattern, round the upper corridor are ranged the Jablochkoff lamps exhibited by the Société Générale d'Electricité, and around the arena stand handsome specimens of the Lontin lamp, mounted on tastefully-designed posts. The Wilde lamp will also be strongly represented. This may be briefly described as the Jablochkoff candle with the central non-conducting substance left out. In addition to a powerful Gramme machine, the British Electric Light Company exhibit several lamps, notably the Serrin, hardly yet surpassed in some points of excellence, the Werdermann, Reynier, Higgins, and Rapieff lights, and it is stated that the Anglo-American Electric Light Company will exhibit the Wallace and the Iridium Incandescent lights, the last-named of which is of much the same kind as that employed by Mr. Edison. The distinguishing characteristics of these various lights were explained by Mr. W. H. Preece, and the exhibition, which will remain open to the public for the remainder of the week, promises to be by far the most attractive display of scientific apparatus made for some considerable time past.

It may not be inappropriate to give here a short account of a new form of electric lighting, which, it would seem, will not be represented at the exhibition now opened at the Albert Hall.

At last week's meeting of the Paris Academy, M. Jamin presented a model of an electric light for which he claims the greatest possible simplicity. The two carbons are kept parallel by two insulated copper tubes, separated by an interval of two or three millimeters, in which they slide by friction, and which serve at once to direct them and to guide the current. They are surrounded by a directing circuit composed of five or six spirals coiled on a thin rectangular frame ·40 m. long and ·15 m. broad. This circuit, traversed by the same current as the carbons, and in the same direction, guides and fixes the electric arc at the extremity of the points. The lighting is effected automatically. For this purpose, the two extremities of the carbons are surrounded by a thin caoutchouc band which keeps them close together. Between them, a little above, a small fragment of iron wire is introduced, which keeps them in close communication by a single point. As soon as the circuit is closed, the current traverses this wire, makes it red-hot, and melts the caoutchouc; the two carbons, thus freed, separate, and the arc is established with a sort of explosion. Carbons of any size may be employed, up to 8 mm. diameter. At this limit the waste scarcely exceeds ·08 m. per hour. By a proper arrangement the points may be maintained in their initial position. The apparatus may be suspended either with the points upwards or directed towards the ground. For several reasons, which Mr. Jamin states, the latter position is preferable. With its points downwards, then, M. Jamin claims for his light the following advantages:—1. That of simplicity, since it requires no mechanism and no preliminary preparation; all is reduced to a support and to carbons; (2) that of mechanical economy, since it succeeds in almost doubling the number of lights; (3) increase of illumination, since each of the new lights is nearly twice as powerful as the old; (4) quality of light, which is more white; (5) a more advantageous arrangement of the poles, which throw their greatest amount of light downwards, where it is required, instead of losing it towards the sky, where it is useless; (6) finally, economy of the combustible material, since the waste is less in proportion to the size of the carbons.

NOTES

WE greatly regret to announce the death at Rome, on April 14, of Prof. Paolo Volpicelli, the well-known Italian electrician. We hope to be able to give details of his life and work in an early number.

THE Council of the Society of Arts have awarded to Sir William George Armstrong, C.B., D.C.L., F.R.S., the Albert Medal "because of his distinction as an engineer and as a scientific man, and because by the development of the transmission of power, hydraulically, due to his constant efforts, extending over many years, the manufactures of this country have been greatly aided and mechanical power beneficially substituted for most laborious and injurious manual labour."

THE annual *conversazione* of the president of the Institution of Civil Engineers has been announced for Monday, May 26. Mr. Bateman, the president, will, by permission of the Lords of the Committee of Council on Education, receive his guests in those galleries belonging to the South Kensington Museum which contain the varied and extensive collection of engineering, naval models, drawing instruments, and machinery. Mr. Bateman invites the members of the profession and others to supplement that collection by the loan for the occasion in question of any similar suitable object.

THE *American Naturalist* states positively that the President has nominated Mr. Clarence King to the directorship of the U.S. Geological Survey, and from an article by Mr. A. S. Packard, in the same number, there seems no doubt that the appointment has been confirmed. The actual state of matters now is that the three surveys under Hayden, Powell, and Wheeler are to be discontinued after June 30, and to be replaced by a new U.S. Geological Survey, in charge of Mr. Clarence King. "It was," Mr. Packard states, "as far as we are aware, the original understanding, when the matter was referred by Congress to the National Academy of Sciences, to simply consolidate the existing geological surveys, but the report of the committee was so worded that these surveys were abolished outright instead of being consolidated. The amount appropriated for the new geological survey is 100,000 dollars, a little more than each of the other surveys has formerly received. Thus the work is apparently to be greatly curtailed, and science and the best interests of the Western people will, in a corresponding degree, suffer." We trust that this is too gloomy a view to take of the prospects of the newly-organised survey, though we fear that personal interests have had more weight in bringing about the new state of things than the interests of science of the United States. We understand from Mr. Packard that no provision has been made for carrying on biological observation along with the geological survey, a department hitherto admirably represented, and the work of which has made the U.S. Survey famous all the world over. We are sure it will not be with Mr. King's consent that zoology and botany will be ignored in the survey under his charge, and he may be sure that men of science of all nations will watch with interest the future work of that survey which hitherto has contributed so largely to scientific knowledge.

THE death is announced of Mr. Frank A. Bradley, a well-known American geologist; he was crushed to death by the caving of a wall of a gold mine in Georgia.

THE United States Congress has appropriated 10,000 dollars for the completion of the investigation of the Rocky Mountains by the United States Entomological Commission. The work during the coming season will be carried on in Colorado and the Western Territories, particularly Utah and Eastern Idaho.

MR. S. H. BRACKETT, of St. Johnsburg Academy, Vermont, writes to the *Scientific American*, claiming for Mr. Edward Farrar, of Keene, N.H., the discovery of the principle of the telephone in 1851. In support of the claim Mr. Brackett gives the following extracts from Mr. Farrar's correspondence of the time:—"Each reed of a melodeon is furnished with a small metallic point, which, while the reed is at rest, approaches near to the surface of mercury in a very small cup underneath the reed, into which the point dips when set in motion. The reeds are connected with one pole of a battery, and the cups with the other. The current is broken with each vibration of the reed. At the remote end of the wire is a temporary magnet, with an armature fixed upon a spring in near proximity to the magnet, and which is affected as a reed at the other end of the line is set in motion. The effect is that the armature vibrates with the reed set in motion, and, the pitch of a sound depending on the rapidity of vibration, it will be the same in the reed and armature. A tune on the instrument will therefore produce a tune on the armature. What may appear somewhat strange, several different tones may be heard when chords are struck upon the instrument. The object of my inquiry was this: *If the current power could be varied by some slight variation of a vibrator to be affected by the atmosphere as the tympanum of the ear is, the supposition is that the sounds of the voice might be reproduced* by the means stated above." When it is remembered that Mr. Farrar penned the above in May, 1854, it is to be regretted, we agree with Mr. Brackett, that he was turned aside from so interesting an inquiry at so critical a point.

THE chief work now in process of publication by the United States Geological Survey, we learn from *Science News*, is Dr. Joseph Leidy's "Monograph of the Fresh-water Rhizopods of North America." It will form a quarto volume of several hundred pages, enriched by numerous plates, and will be the twelfth of the series of "Final Reports." The author has been long engaged upon this book, and brings to the elucidation of this subject unequalled knowledge of the branch of which he treats. The introductory chapter furnishes a general account of the rhizopods, giving the characteristics which serve to identify them, telling where they dwell, how they live, in what way to catch them, and the proper method for studying them under the microscope and otherwise. The class Rhizopoda, Dr. Leidy separates into five orders, as follows: Protoplasta, Heliozoa, Radiolaria, Foraminifera, and Monera. Dr. Leidy confines himself to those species which inhabit American ponds and rivers.

THE following questions are proposed by the Belgian Academy for competitive treatment (the rewards offered being medals of 800 francs value each, except for the third of the first section, where the value is raised to 1,000 francs):—I. Section of Mathematical and Physical Sciences—1. Show the state of our knowledge of phenomena known under the name of *influence of masses*, and indicate why the ideas of Berthelot have yielded to those of Proust; also indicate, if possible, the way by which a solution of the general problem may be arrived at. 2. Find and discuss the equations of some algebraic surfaces of no mean curvature. 3. Complete, by new experiments, the state of our knowledge of the relations which exist between the physical and the chemical properties of simple and of compound substances. II. Section of Natural Sciences—1. Give a description of the tertiary strata belonging to the eocene series, that is to say, terminated superiorly by the Laekenian system of Dumont, and situated in Hesbaye, Brabant, and Flanders. 2. Describe the history of the germinative vesicle in ova capable of developing by parthenogenesis. (The author is free to choose any animal species in which parthenogenetic development has been proved to exist.) 3. New observations on the relations of the pollinic tube with the ovule, in one or more phanerogams. The memoirs to be clearly written in French, Flemish, or Latin, and sent, with motto and sealed packet, to the secretary, before August 1, 1880. Great exactness required in citations. Two questions are also proposed for 1881:—1. New researches on the germination of seeds, especially on the assimilation of nutritive deposits by the embryo. 2. Extend to eight points of a curve of the third order, the enharmonic property of four points of a conic.

THE Carpi prize of the Reale Academie de' Lincei for 1880 (value 500 lire) will be awarded to the author of the best monograph *On the Organs and Vital Functions of Plants*. Memoirs to be sent in before December 31, 1880. The conditions are the same as in 1878.

A NEW nautical instrument, called a *navisphere*, has been brought before the French Academy by M. De Magnac. It is meant to indicate, without calculation and promptly, the names of the stars above the horizon at a given moment (with altitude and azimuth), the angle of route for going from one point to another by the arc of a great circle, and the distance between these points (approximately). Spherical triangles may also be solved with it. The instrument consists of two parts, the one a celestial sphere with stars marked on it, resting on a spherical zone, to which all possible positions may be given; the other comprises the system of the horizon, the meridian, and the vertical, represented by a circle, a semicircle, and a quarter of a circle in metal. With this system of arcs one can trace arcs of a great circle on the sphere, and measure their lengths, also measure the angles formed by two great circles. The second part of the apparatus is called a *metrosphere*. The experiments with the *navisphere*, made on board the Atlantic steamship *Washington* appear to have been highly encouraging.

IN the spectral examination of the new earth recently extracted from erbine by M. Nilson, M. Thalén found the following lines proper to the spectrum of that substance. (*Comptes Rendus*, March 24.)

Colour of rays.	Wave-length.	Intensity.	Remarks.
Orange	6078·5	3	Broad and nebulous.
	6072·5	3	
	6054·0	5	Nebulous.
	6035·0	2	
	6019·0	4	Nebulous.
Yellow	5736·0	6	
	5729·0	6	
	5719·0	4	Very fine and clear.
	5710·5	4	
	5700·0	4	
	5686·0	4	
	5671·0	4	
	5657·5	4	
	5526·0	2	Strong.
Green	5089·0	6	Fine.
	5084·5	5	
	5082·3	4	
	5081·0	3	
	5030·0	3	
Blue	4742·5	3	
	4739·0	4	
	4736·5	5	
	4733·0	5	
Indigo	4404·0	„	
	4373·0	„	
	4323·0	„	
	4319·0	„	
	4313·0	„	
	4245·5	„	

Besides these lines, several others were observed which belong to the spectrum of ytterbium, and which have already been indicated by M. Höglund in the spectrum of erbium. For the new element M. Nilson proposes the name *scandium*, to denote its peculiarly Scandinavian origin.

THE International Congress of Americanists has issued its circular of invitations to a third session, to be held at Brussels from September 23 to 26, under the patronage of the King of Belgium and the presidency of the Count of Flanders. The city of Brussels will take charge of the Congress, and see to the proper accommodation and convenience of the members. The object of this organisation is the development of a knowledge of the early history of discovery and settlement in the Americas, as also all such facts in their prehistory as can be gathered by an inspection of the remaining monuments. The volumes of *Proceedings* contain a great deal of interesting and important matter, although the Society is rather open to the charge of credulity in accepting, apparently without question, many statements repudiated by American archæologists. This, however, would be remedied by a larger representation from North America; and it is much to be hoped that some of our more accomplished American historians and ethnologists may take part in the proceedings of the coming season.

IT is known that the first aërial voyage was made by Pilatre de Rozier, in company with the Marquis d'Arlandes, in a Montgolfiere, or heated air balloon, on November 21, 1783. Pilatre was also the first victim of aërostation; he perished along with his companion Romain by the fall of a balloon at Boulogne. Three pieces which belonged to the unfortunate physicist are exhibited in the museum there: his speaking-trumpet, mercury barometer, and thermometer. Recently some other precious relics from the same origin have been found in a drawer in the museum. They are chiefly a plaster medallion of Pilatre, a part of the painted cloth which covered the gallery of the balloon, and the flagstaff. Engravings of these and the former relics of Pilatre are given in a recent number of *La Nature* (April 26), which also reproduces a detailed account of the fatal ascent.

THE extent of variability in composition of atmospheric air is a question treated by Herr von Jolly in a recent communication to the Bavarian Academy. By two methods of measurement, the one eudiometric, the other based on weighing, he observed variations that are not quite inconsiderable. The air samples of the year 1877 (got 2 km. out of town) showed differences in the oxygen from 21·01 down to 20·53 per cent., and in 1875 to 1876 the highest and lowest proportions (obtained by weighing) were 20·96 and 20·47 per cent. respectively. The variations in the two years were thus nearly the same. The largest amount of oxygen occurred in both years when the polar current was prevalent; the smallest with the equatorial current or föhn. It is not affirmed, however, that whenever the wind is north or north-east, there is necessarily *more* oxygen, and when it is south and south-west, *less*; or that differences of 0·5 per cent. occur with every reversal of the wind. The more rapidly the directions of wind alternate, there is more mixture of air masses; and therefore there is never so much oxygen as with continuous polar current, or so little as with continuous equatorial. Whether from year to year the mean proportion of oxygen is the same, or whether, as is more probable (the duration of polar and equatorial currents varying from year to year), there are slight differences in this average, can only be determined by further observations.

DURING the conjunction of the planets Mercury and Venus, on September 30 last year, measurements of their relative power of light-reflection were made at Strasburg Observatory (we learn from *Astr. Nachr.*) by Herr Schnur. The half-objective of the telescope which showed Venus was gradually shaded by measurable quantities till equal surface-portions of Venus appeared of the same brightness as those of Mercury through the unshaded part. The measurements on September 30 gave for relative light intensity the value 6·75, and on October 2 the value 5·36; the latter figure is considered the more reliable, and may be accepted for the relative brightness of Mercury and Venus. Herr Zöllner, by a quite different method, got 5·5.

APPLICATIONS for the intended Exhibition of Applied Science in Paris may be sent to M. Nicolle, director, 10, rue de Lancry, Paris. The presidency of the Patronage Committee has been accepted by M. Jules Simon. More than 200 English firms have already sent in their adhesion, and more than 300 German firms wish to protest against the abstention imposed by their own Government in 1878. A large number of these belong to

Alsace-Lorraine. The exhibition will keep open from July 15 to the end of November, but a limit will be imposed on exhibitors sending in their applications.

ON April 27 an earthquake was felt at Florence, and also at Bologna. The Florence commotion was very slight, but had been preceded by other movements of a similar nature, which ought not to pass unnoticed, especially in connection with the seismic manifestations felt in Germany, as mentioned in our last impression.

MR. ROWLAND WARD writing to the *Standard*, states that in making the excavation at Charing Cross for Messrs. Drummonds' new bank, the workmen, at depths varying from fifteen to thirty feet, came upon the fossil remains of various extinct animals. They include elephant tusks and molars (probably the mammoth *Elephas primigenius*), teeth and numerous bones of the gigantic extinct ox (*Bos primigenius*), a portion of the horn of the great extinct Irish deer (*Megaceros hibernicus*), along with various other remains of ruminating animals not yet identified. The specimen in this series which has specially attracted notice is the extreme end of a tusk unusually sharp at the point and highly polished, and from a portion of the surface of which a very thin skin of ivory peels off, exposing a strongly and regularly longitudinally channelled surface beneath.

MR. WATSON LYALL'S "Sportsman's and Tourist's Guide" improves every year. It has now reached its seventh year, and is evidently a great success. The information as to shootings, rivers, lochs, &c., of Scotland is as full as could be, and is evidently kept well up to date. It deserves all the success it has obtained. In this connection we greatly regret to see that the disease which we referred to last year as having broken out among the Solway salmon has reappeared this year, not only in the Solway rivers, but in the Tweed. Mr. Sterling, of the Edinburgh Anatomical Museum, found it to be a branching fungus (*Saprolegnia ferax*), which, first attacking the scaleless parts, rapidly spreads over the whole fish. The disease has not yet appeared north of the Tweed. Sir Robert Christison recommends a Royal Commission, and the careful watching of all salmon and trout streams, whether affected or not.

WE are glad to see from its Twenty-first Report that the East Kent Natural History Society is fulfilling its functions, though under many disadvantages.

WE have already referred to the forthcoming annual meeting, at Leicester, of the Midland Union of Natural History Societies. Those interested in the meeting will find further details in our advertisement columns.

IN Prof. Jevons's article (vol. xix. p. 588), second column, line 18, for "a seer is equal to about 21 lb. avoirdupois," read "a seer is equal to about 2 lb. avoirdupois." The error is a purely typographical one, and does not affect any other statements in the article. Mr. E. H. Pringle asks us to state that in his letter (vol. xx. p. 6), "such distances as six," &c., should be "such heights as six," &c., and "mountain 20,000 feet high (less than 4 miles)" should be "mountain 10,000 feet high (less than 2 miles)." He thinks it may be worth mentioning that Raoul or Sunday Island, in the Kermadecs, has an elevation of 1,627 feet, commanding a sea horizon of nearly 50 miles radius.

THE additions to the Zoological Society's Gardens during the past week include a Bonnet Monkey (*Macacus radiatus*) from India, presented by Mr. E. Brett; a Pig-tailed Monkey (*Macacus nemestrinus*), from Java, presented by Mr. E. M. Clissold; a Black-faced Spider Monkey (*Ateles ater*) from Eastern Peru, two Passerine Ground Doves (*Chamæpelia passerina*) from America, presented by Capt. H. King; an Ocelot (*Felis pardalis*) from America, presented by Mr. B. H. Jones; a Crab-eating Raccoon (*Procyon cancrivorus*) from South America, presented by Mr. Bridget; a Long-tailed Marmot (*Arctomys caudata*) from Bhootan, presented by Capt. Greenstreet, R.E.; a Silver Pheasant (*Euplocamus nycthemerus*) from China, presented by Mr. E. J. Beagle; a Small Hill Mynah (*Gracula religiosa*) from South India, presented by Mr. J. W. Wodler; five Water Ouzels (*Cinclus aquaticus*), British Isles, presented by Mr. F. Swabey; an Anaconda (*Eunectes murinus*) from South America, presented by Mr. G. H. Hawtayne, C.M.Z.S.; a Teguexin Lizard (*Teius teguexin*) from South America, a Leopard Tortoise (*Testudo pardalis*) from South Africa, purchased; a Tamandua Ant-eater (*Tamandua tetradactyla*) from South America, a Great American Egret (*Ardea egretta*) from America, deposited; a Reeves's Muntjac (*Cervulus reevesi*) born in the Gardens.

RECENT CONTRIBUTIONS TO THE HISTORY OF DETONATING AGENTS[1]

II.

THAT the power possessed by different very highly explosive substances, of inducing the detonation of such bodies as gun-cotton and nitro-glycerine, is not solely ascribable to the operation of mechanical force very suddenly developed, is indicated not only by the singular inertness of gun-cotton to the influence of nitro-glycerine as a detonating agent, but also by a comparison of the behaviour of other detonating substances with that of the mercuric fulminate, when applied to the detonation of gun-cotton. Thus the detonation of silver fulminate is very decidedly sharper than that of the mercury compound, yet it is in no way superior to the latter in its power as an initiative detonating agent; indeed, a somewhat larger amount of it appeared to be required than of the mercury salt to induce detonation of gun-cotton with certainty. Again, the iodide and chloride of nitrogen are far more susceptible of sudden detonation than the silver fulminate; yet while 5 grains of the latter, confined in a stout metal envelope, suffice to detonate gun-cotton, 50 grains of chloride of nitrogen confined by water, appeared to be the minimum amount with which the detonation of gun-cotton could be accomplished with certainty, while no success attended the employment of confined iodide of nitrogen in quantities ranging up to 100 grains.

The incompatibility of these results with the general conclusion, based upon numerous and greatly varied experiments, that the facility with which the detonation of gun-cotton and nitro-glycerine, and bodies of a similar character as explosives, is induced by an initiative detonation, is proportionate to the mechanical force aided by the heat developed by the latter, led the lecturer to the conclusion that a synchronism or similarity in character or quality of the vibrations developed by the detonation of particular substances, operates in favouring the detonation of one such substance by the initiative detonation of a small quantity of another, while in the absence of such synchronism, a much more powerful detonation, or the application of much greater force, would be needed to effect the detonation of the material operated upon. This view has received considerable support from results since obtained by other experimenters, especially by MM. Champion and Pellet; but the subject is one which still needs further experimental elucidation.

The physical character of explosive substances, as also the mechanical condition of a mass of the particular explosive substance operated on, are of great influence in determining its behaviour when submitted to the action of an initiative detonation. The liquid nitro-glycerine is far more sensitive to detonation than gun-cotton; one grain of mercuric fulminate, confined in a metal case, suffices to detonate nitro-glycerine when surrounded by it; but, in order to attain this result with any degree of certainty, it is necessary so to confine the nitro-glycerine as to prevent its yielding to the blow developed by the initiative detonation, and thus to some extent escaping from the operation of the sudden concussion to which the particles contiguous to the fulminate charge are submitted.

If nitro-glycerine be mixed with solid substances in a fine state of division, plastic mixtures may be obtained, and the liquid may thus be presented in something like a solid form to the

[1] Weekly Evening Lecture at the Royal Institution, Friday, March 21, 1879. By Professor Abel, C.B., F.R.S. Revised by the Author. Continued from p. 21.

detonating agent; if the particles of absorbent material be, moreover, of porous nature, as is the case with the infusorial earth called kieselguhr, used in the production of dynamite, a solid nitro-glycerine preparation may be obtained which contains a very large proportion of the liquid (75 per cent. by weight). In this condition nitro-glycerine may be detonated without any difficulty when freely exposed to air; and although it is diluted with a considerable proportion of absolutely inert material, its sensitiveness to detonation is not in the least diminished. Each particle of the diluent is enveloped in the liquid, so that no portion of the latter becomes isolated from the remainder by the admixture of inert solid matter; hence, when the initiative detonator is surrounded by such a mass, it is in contact at all points with some portion of the nitro-glycerine, and the latter is in continuous connection throughout, though no longer in a mobile condition; detonation is consequently as readily established and transmitted through the mass as though it consisted entirely of nitro-glycerine. Indeed, while the liquid in its undiluted state, if freely exposed to air in a long layer, transmits detonation with difficulty, and very slowly as compared with compressed gun-cotton (the observed rate of progression being, in several experiments, below 6,000 feet per second), detonation is transmitted with ease and certainty through very long trains of a solid preparation of nitro-glycerine, such as dynamite, and the rate of transmission is decidedly more rapid than it is with compressed gun-cotton, a result which is in harmony with the greater sensitiveness to detonation and the greater violence of action of nitro-glycerine.

It has already been stated that gun-cotton may be detonated if a confined charge of not less than two grains of mercuric fulminate be detonated when closely surrounded by the substance. But in order to attain this result, the cellulose-product must be presented to the detonating agent in a mechanical condition favourable to its action.

Gun-cotton in a loose flocculent condition, or even if in the more compact form of a spun yarn or thread, cannot be detonated through the agency of a large charge of fulminate buried in the material. It is simply scattered with violence, portions being sometimes inflamed by the heat developed where the fulminate is detonated. If however, the gun-cotton be converted into a compact form, either by ramming the wool or thread very tightly into a case, or better still, by reducing the gun-cotton fibre to a very fine state of division, and then compressing it into compact masses, it becomes susceptible of detonation by the initiative action of mercuric fulminate, and the quantity of the latter required to bring about detonation is small in proportion as the compactness or density of the compressed material is increased.

Detonation, when established in compressed gun-cotton, is transmitted with great velocity throughout the mass, as already stated, or from one to another of contiguous masses, and even, though at a reduced rate, if small spaces exist between the individual masses. But, if a small mass of compressed gun-cotton freely exposed to air be detonated when in immediate contact with gun-cotton wool or loosely-twisted yarn, the detonation will not be transmitted to these, but they will merely be scattered and perhaps inflamed.

The difference in the behaviour of nitro-glycerine and of gun-cotton when presented to the action of a so-called initiative detonation under the different conditions spoken of above, admits of ready explanation.

It has been thoroughly established that the action of an initiative detonation is not ascribable to the heat developed within the detonating material itself, in undergoing chemical metamorphosis. Its action has already been compared to that of a blow from a hammer or falling weight. The readiness and certainty with which gunpowder, gun-cotton, and other explosive agents are detonated by the latter agency are regulated by several circumstances; they are in direct proportion to the weight of the falling body, to the height of its fall, and to the force with which it is impelled downwards; to the velocity of its motion; to the mass and rigidity or hardness of the support upon which the substance to be detonated rests; lastly, to the quantity and mechanical condition of the explosive agent struck, and to its sensitiveness.

Gunpowder is much more readily detonated by a sharp blow from a small hammer than by the simple fall of a heavy hammer, or by a comparatively weak blow from the latter. It is very difficult by repeated blows, applied at very brief intervals, to detonate gun-cotton if placed upon a support of wood or lead, both of which materials yield to a blow, the force applied by that blow being transferred through the explosive agent and absorbed in work done upon the material composing the support. But if the latter be of iron, which does not yield permanently to the blow of the hammer, the detonation of those substances is easily accomplished. If the quantity of the explosive agent employed be so considerable as to form a thick layer between the hammer and support, the force applied is to so great an extent expended in imparting motion to the particles of the compressible mass, that there remains little or none by which its detonation can be accomplished, and if the material be in a loose or porous condition (as in the case of a powder or of loose wool), much work has to be accomplished in moving particles of the mass through a comparatively considerable space, in the operation of compressing them, so that a second or even a third blow is required for their detonation; whereas if, by blows or pressure previously applied, the explosive material will be presented in the form of a compact mass, the particles of which have little tendency to motion when force is applied to them, detonation will be much more readily developed. It appears, therefore, that the detonation of an explosive substance by means of a blow is the result of the development of heat sufficient to bring about most energetic chemical action, or change, by expenditure of force in the compression of the material, or by establishing violent friction between its particles, consequent upon the motion momentarily imparted to them, and that it is brought about with a readiness proportionate to the resistance which they oppose to their motion by the degree of their contiguity to each other.

The exceedingly violent motion of particles resulting from the sudden or extremely rapid transformation of a solid or liquid explosive body into highly heated gas or vapour (which is the effect of a detonation), must obviously exert force which operates upon a body opposed to it in a manner precisely similar to the force applied by opposing a body in the path of a solid mass which is set into very rapid motion. The power of accomplishing the detonation of nitro-glycerine, gun-cotton, or other highly explosive substances, freely exposed to the air, through the agency of detonation produced in their vicinity or in close contact with them, appears therefore correctly ascribable to the heat suddenly developed in some portion of the mass by the mechanical effect, or blow exerted by that detonation, and is regulated by the violence and suddenness (either singly or combined) of the detonation, by the extent to which the particles composing the mass of the explosive material are in a condition to oppose resistance to the force, and by the degree of sensitiveness of the substance to detonation, or to sudden metamorphosis, under the influence of heat thus developed.

It will now be evident why the readily yielding nature of the particles of liquid nitro-glycerine tends to counteract its great sensitiveness to detonation, and why, when the motion of the liquid particles is impeded by their admixture with solid matter, and when they are consequently placed in a position to resist mechanical motion by the force applied through the agency of detonation, its natural sensitiveness to detonation, and the rapidity with which it can be transmitted from particle to particle become fully developed.

Again, the reduction of gun-cotton fibre to a fine state of division, which renders the material readily convertible into very compact and dense masses, places the particles in the condition most favourable to resist mechanical motion upon the application of a blow, or of the concussion resulting from a detonation; hence, compressed gun-cotton is readily susceptible of detonation in proportion to the extent of compression, or to its density and compactness, while loose gun-cotton wool, or the lightly twisted or compressed material cannot be readily detonated, because the force applied is expended in imparting motion to the readily yielding particles of the mass. If the force applied through the agency of a detonator to a mass of explosive material just borders upon that required for the development of the detonation, or if the condition of the mass is such as hardly to present the requisite resistance to mechanical motion essential for its detonation, then, results intermediate between the mechanical dispersion of the mass and its violent chemical dispersion or disintegration, *i.e.*, detonation, are obtained. Thus, frequent instances have been observed, especially in the experiments in the transmission of detonation through tubes, in which the initiative detonation has brought about an explosion attended with little, if any, destructive effect, portions of the mass being at the same time dispersed and occasionally inflamed. Even silver fulminate, which under ordinary conditions detonates

violently, even when only a particle of the mass is subjected to a sufficient disturbing influence, has been exploded without the usual demonstrations of force, by the transmitted effect of a detonation of mercuric fulminate. In these instances the violence of the concussion produced by the initiative detonation was only just bordering on that required for the development of detonation, and it appears probable that only some small portion of the mass operated upon was in a condition or position favourable to the action of the initiative blow. The remainder of the mass would then be dispersed by the gases developed from the detonated portion; in some instances the particles would be inflamed at the moment of their dispersion, in others, they would even escape ignition.

Some experiments made in firing at masses of compressed gun-cotton, differently arranged and of different thicknesses, with a Martini-Henry rifle, at short ranges, afforded interesting confirmation of the correctness of the explanation given of the operation of a blow upon masses of explosive material under different conditions. Disks of gun-cotton of the same density and diameter, but differing in thickness, were fired at; they were freely suspended, and their distance from the marksman was in all instances 100 yards. The thinnest disks were simply perforated by the bullets; somewhat thicker disks were inflamed by the impact of the bullet, while still thicker disks, fired at under the same conditions, were exploded. No instance of detonation was, however, obtained. These differences in effect, obtained with masses of different thickness and weight, are due to the difference in their power to resist mechanical motion when struck by the bullet, and in the different amount of resistance to penetration presented by the thin and the thicker disks.

It has been explained that nitro-glycerine may be largely diluted with inert solid matters without its sensitiveness to detonation being reduced, while its detonation in open air becomes very much facilitated, because the tendency of its particles to yield to the force of a blow or detonation, is very greatly diminished. But if a *solid* explosive agent is diluted with inert *solid* matter the case is different; for in such a mixture of the finely divided solid with non-explosive solid particles, there must be a partial and sometimes a complete separation of the particles of the explosive by the interposed inert particles with which it is diluted; hence the sensitiveness to detonation is reduced, and its transmission by the particles is retarded or altogether impeded, by a diminution of the extent of contact between the substance to be detonated and the initiative detonation, and by the barrier which the interposed non-explosive particles oppose to the transmission of detonation. In experiments made in this direction with finely divided gun-cotton, it was found that although dilution with an inert solid, applied in the *solid form*, reduced the sensitiveness of the material to detonation, this was not the case when it was incorporated with a salt soluble in water, the mixture being then compressed while in the wet state. The compressed masses thus obtained were, when dried, in a condition of greater rigidity than could be attained by submitting undiluted gun-cotton to considerably more powerful pressure, because the crystallisation of the soluble salt used as the diluent upon evaporation of the water, cemented the particles composing the mass more rigidly together. The gun-cotton was therefore presented in a form more capable of resisting the mechanical action of a small charge of fulminate, than a more highly compressed undiluted gun-cotton, and hence the reduction in sensitiveness due to the detonation of the explosive compound is nearly counterbalanced by the greater rigidity imparted to the mass. If a soluble oxidising agent (a nitrate or chlorate) be employed as the diluting material, the predisposition to chemical reaction between it and the gun-cotton (which is susceptible of some additional oxidation), appears to operate in conjunction with the effect of the salt in imparting rigidity to the mixture, thus rendering the latter quite as sensitive to the detonating action of the minimum fulminate charge as undiluted gun-cotton. Moreover, the interesting fact has been conclusively established, that these compressed mixtures of gun-cotton with a nitrate or a chlorate are much less indifferent to the influence of detonating nitro-glycerine than gun-cotton in its pure state, chlorated and nitrated gun-cotton being detonated with certainty by means of ½ oz. of nitro-glycerine.

If compressed gun-cotton is diluted by impregnating the mass with a *liquid*, or with a solid which is introduced into the mass in a fused state, its susceptibility of detonation is reduced to a very much greater extent than by a corresponding quantity of a solid inert body, incorporated as such with the gun-cotton, the cause being the converse of that which operates in preventing a reduction of the sensitiveness to detonation of nitro-glycerine by its dilution with an inert solid. In this case the explosive liquid envelopes the solid diluent, and remains continuous throughout, occupying the spaces which exist between the solid particles; hence detonation is readily established and transmitted. But in the case of the solid explosive the diluent, which is liquid, or at any rate is introduced into the mass in the liquid state, envelopes each particle of the solid, so that a film of inert material surrounds each, isolating it from its neighbours, and thus opposing resistance to the transmission of detonation, which is proportionate to the original porosity or absorbent power of the mass.

While compressed gun-cotton, in the air-dry state, is detonated by 2 grains of mercuric fulminate imbedded in the material, its detonation by 15 grains, applied in the same manner, becomes doubtful when it contains 3 per cent. of water, over and above the 2 per cent. which exists normally in the air-dry substance. Specimens which had been impregnated with oil or soaked in melted fat and allowed to cool could not be detonated by means of 15 grains of fulminate. These diluted samples of gun-cotton could only be detonated by adding very considerably to the power of the initiative detonation; 100 grains of confined fulminate generally failed to detonate gun-cotton containing from 10 to 12 per cent. of water, and if the amount reached 17 per cent., 200 grains of fulminate were needed to insure its detonation.

But moist or wet compressed gun-cotton is decidedly more susceptible of detonation by (dry) compressed gun-cotton itself than by mercuric fulminate.

Thus 100 grains of dry gun-cotton, detonated through the agency of the ordinary fulminate fuze, suffice to detonate wet gun-cotton containing 17 per cent. of water, though this result is somewhat uncertain. If the diluting agent amounts to 20 per cent., detonation is not certain with less than 1 oz. of dry gun-cotton, and if the compressed material be completely saturated with water (*i.e.*, containing 30 to 35 per cent.), 4 oz. of the air-dry substance, applied in close contact, are needed to insure its detonation.

Detonation is transmitted through tubes from dry compressed gun-cotton to a moist disk of the material with the same facility as to the dry substance; and this is also the case with regard to the propagation of detonation from one mass of moist gun-cotton to another, in open air, all the pieces being ranged in a row, in contact with each other, provided that the piece first detonated does not contain less water than the others to which detonation is transmitted.

Gun-cotton containing 12 to 14 per cent. of water is ignited with much difficulty on applying a highly heated body. As it leaves the hydraulic press upon being converted from the pulped state to masses having about the density of water, it contains about 15 per cent. of water; in this condition it may be thrown on to a fire or held in a flame without exhibiting any tendency to burn; the masses may be perforated by means of a red-hot iron or with a drilling tool, and they may with perfect safety be cut into slices by means of saws revolving with great rapidity. If placed upon a fire and allowed to remain there, a feeble flame flickers over the surface of the wet gun-cotton from time to time as the exterior becomes sufficiently dry to inflame; and in this way a piece of compressed gun-cotton will burn away very gradually indeed. A pile of boxes containing in all 6 cwt. of gun-cotton, impregnated with about 20 per cent. of water, when surrounded by burning wood and shavings in a wooden building was very gradually consumed, the gun-cotton burning as already described when the surfaces of the masses became partially dried. Quantities of wet gun-cotton of 20 cwt. each, packed in one instance in a large, strong wooden case, and, in the other, in a number of strong packing cases, have been placed in small magazines, very substantially constructed of concrete and brickwork. Large fires were kindled around the packages in each building, the doors being just left ajar. The entire contents of both buildings had burned away, without anything approaching explosive action, in less than two hours. This comparatively great safety of wet gun-cotton, coupled with the fact that its detonation in that condition may be readily accomplished through the agency of a small quantity of dry gun-cotton, which, through the medium of a fulminate fuse or detonator, is made to act as the initiative detonating agent, gives to gun-cotton important advantages over other violent explosive agents for purposes which involve the employment of more or less considerable quantities

at one time, on account of the comparative safety attending its storage and the necessary manipulation of it. Moreover, it has been well established by experiments of many kinds carried out on a considerable scale, as well as by accurate scientific observations, that the detonation of wet gun-cotton is decidedly sharper or more violent than that of the dry material; a circumstance which affords an interesting illustration of the influence exerted by the physical condition of the mass upon the facility with which detonation is transmitted from particle to particle. In the determinations made by means of the Nobel chronoscope, of the velocity with which detonation is transmitted along layers or trains of gun-cotton and nitro-glycerine, the lecturer has included experiments with gun-cotton containing different proportions of water. When the material contained 15 per cent. of the liquid, some indications were obtained that the rate of transmission of detonation was a little higher than with dry gun-cotton; the difference was very decidedly in favour of wet gun-cotton, when the latter was thoroughly *saturated* with water. The air in the masses of compressed gun-cotton being replaced entirely by the comparatively incompressible body, water, the particles of explosive are in a much more favourable condition to resist displacement by the force of the detonation, and hence they are more readily susceptible of sudden chemical disintegration. Moreover, the variations in the rate of travel of detonation in dry gun-cotton, resulting from differences in the compactness or rigidity of different masses of the material, are very greatly reduced, if not entirely eliminated, by saturating the disks with water, and thus equalising their power of resisting motion by a sudden blow.

Another striking illustration of the influence which the physical character of an explosive substance exercises over its susceptibility to detonation and the degree of facility with which its full explosive force is developed, is furnished by one of the most recently devised, and one of the most interesting of existing, explosive agents.

Twelve years ago, soon after the process of producing compressed and granulated gun-cotton had been elaborated by the lecturer, it occurred to him to employ these forms of gun-cotton as vehicles for the application of nitro-glycerine. A considerable proportion of the liquid was absorbed by the porous masses of gun-cotton, and a nitro-glycerine preparation analogous in character to dynamite was thus obtained. The absorbent was in this case a violently explosive body instead of an inert solid as in dynamite, but the quantity of nitro-glycerine in a given weight of the preparation (to which the name of glyoxilin was given), was considerably less than in the kieselguhr-preparation; hence the latter was nearly on a point of equality with it, in regard to power, as an explosive agent.

(To be continued.)

NOTES FROM RUSSIA

GEOGRAPHY AND ANTHROPOLOGY.—At the last meeting, April 23, of the Imperial Russian Geographical Society, M. Sreznefsky, the Secretary, communicated his monthly report on the work of the Society. This consisted in equipping three expeditions in which the Society intends to take part, and its participation in the Anthropological Exhibition of Moscow. The first expedition is the cruise of the steamer *Nordenskjöld*, equipped by the well-known merchant of Siberia M. Sibiriakoff, for the relief of Prof. Nordenskjöld in the *Vega*. It will proceed from Malmö direct to Yokohama, Behring Strait, and beyond. According to the request of M. Sibiriakoff the Society appointed to accompany the expedition M. A. W. Grigorieff, an accomplished botanist, known for his dredging work in the White Sea, where he collected very interesting specimens of marine fauna with deep soundings and temperature observations, by means of a Negretti and Zambra deep-sea thermometer. He proceeds to Malmö to join the expedition, with a Dent chronometer from the Society, and a complete provision for zoological collections, and a sufficient provision of alcohol.

The second expedition is sent out by the Ministry of Public Works, for the exploration of the old bed of the Amu-daria (Usboi), and to investigate the possibility of turning the river to the Caspian; it will be under the direction of Major-General A. T. Gloukhofskoi, an experienced traveller in Central Asia. The Society sends two Fellows with the expedition, a geologist, Prince Sedroiz, and the economist, N. A. Majef, the manager of the *Turkestan News*, a collector of varied statistical materials in Turkestan. The third expedition, of a private character, is to explore for a railroad from Orenburg to Tashkent, and the possibility of navigating with steamers the Sir and Amu-daria. By order of the Emperor a sum of 5,000 roubles is placed at the disposal of the Society.

The Anthropological Exhibition was opened in Moscow on April 15, under the superintendance of the Society, which has sent a great number of valuable objects of an ethnological character, with craniological collections and prehistorical specimens, tumuli excavations, and a valuable collection belonging to the Czarevich. All these collections were arranged by M. Sreznefsky, the Secretary of the Society, who was sent as its representative to the opening of the exhibition. The aim of this exhibition is: (1) To contribute to the development of anthropology as a science. (2) The foundation of an anthropological museum for the teaching of anthropology in the University of Moscow. (3) To popularise the science.

The exhibition is divided into sections—prehistorical, anthropological, medico-anthropological, photographical, ethnographical, the history of Russian types.

At the end of the meeting of the Society M. Alenitzin communicated his paper on the history of the Amu-daria question; he criticised the different opinions on the possibility of turning the Amu-daria into the Caspian, and doubted whether this question could be resolved practically and in a positive manner.

A. LOMONOSSOFF

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

THE Council of the Society of Arts having received an application from the City and Guilds of London Institute for the Advancement of Technical Education, offering to take charge of the technological examinations established by this Society in 1873, and carried on to the present time, have resolved to transfer these examinations to the charge of the Institute. The Council have also ascertained that the Science and Art Department will assist the City Institute in conducting the examinations, in the same way as it has hitherto assisted the Society of Arts. The technological examinations for the present year will, therefore, be carried on under the direction of the Institute, and all communications on the subject should be addressed to the Hon. Secretaries, City and Guilds of London Institute, Mercer's Hall, E.C.

THE following is the result of the recent examination for the Public Schools Prize Medals of the Royal Geographical Society: Physical Geography (examiner John Ball, F.R.S.), gold medal, Matthew George Grant; silver medal Frank Taylor Sharpe, both of Liverpool College. Honourably mentioned: E. G. Harmer, University College School; H. Ll. Smith, Bristol Grammar School; F. S. Carey, Bristol Grammar School; A. T. MacConkey, Liverpool College. Political Geography (examiner Canon Tristram, F.R.S.), gold medal, David Bowie, Dulwich College. Silver medal, Claude L. Bickwell, Harrow School. Honourably mentioned, J. F. Naylor, Dulwich College; W. H. D. Boyle, Eton; A. D. Rigby, Liverpool College; Theod. Brooks, London International College; R. A. Fawcett and A. C. Painter, of Clifton College.

ON May 1 an interesting ceremony took place at St. Barbe, the principal free institution at Paris. Two bodies of pupils were marched under the direction of teachers; the first was going to the Gare du Nord in order to come to London and spend six months in a corresponding English institution to learn the English language; the other went to the Gare de l'Est to proceed to Germany. These pupils have already learned foreign languages in Paris. They are placed under the supervision of professors, so that the usual routine of their studies for French honours should not be interrupted in any way.

SCIENTIFIC SERIALS

Annalen der Physik und Chemie, No. 3.—In view of contradictory results got by Sir W. Thomson and M. Le Roux, with regard to the thermo-electric behaviour of stretched wires, Herr Cohn has made a number of experiments, here described in an inaugural dissertation. He finds that the intensity of the thermo-current between stretched and unstretched wire of the same metal, depends (apart from all *permanent* properties), not only on the present tension of the former, but also, in very different

degree according to the material used, on the upper and lower limits between which, since the last complete release from tension, the tensions have varied (the *succession* alone, not the *time*, being here determinant). In a thermo element of two similar wires, stretched with equal weights, but of which one (a) has last borne a greater, the other (b) a less weight, the current flows from b to a. In iron and steel the previous tensions even affect the direction in which the thermo-current varies with increasing or decreasing tension. Taking the direction of the current which arises with the *first* weak stretching, it is opposite for hard and soft wires, and the discordance above referred to is thus explained. Herr Cohn thus formulates his general conclusion: "A stretched wire behaves, *ceteris paribus*, differently, according as it has before been stretched more weakly or more strongly, and this difference continues till the next alteration of the tension."—Herr R. Weber contributes a useful paper on the chemical composition of glasses with relation to their resistance to atmospheric influences. He finds that the composition of many well tested lime alkali glasses approximates the proportions $6SiO_2$, $1CaO$, and $1K_2O$ or Na_2O; but also, in good glasses, there may be more alkali, if it be compensated with more than 6 equivalents of silicic acid; and less silicic acid may be allowed if the lime be diminished relatively to the alkali.—The transmission of high tones through the telephone is discussed by Herr Hagenbach. From his experiments it appears that the (upper) limit of audibility with the instrument is commonly about two octaves lower than in direct hearing. The cause is found not in the line, nor in the magnet, but in the plate, which, when the variations of magnetism exceed a certain number per second, no longer keeps up with them.—Herr Aron gives a mathematical study of the microphone; *inter alia*, it is shown that, whereas in the telephone the "clang tint" is exalted, in the microphone it is lowered.—Herr Herwig prosecutes his study of liquid cells as condensers; considering the charge of cells, first by large constant batteries, then by small forces (both acting shortly), and comparing the full charges in cells containing liquids of different resistances.—We further note a new hygrometer by Herr Edelmann, based on the fact that if any space be filled with atmospheric air, and the aqueous vapour then removed, without altering the volume, the pressure decreases by the amount of tension of this vapour. A sinus manometer for measuring small differences of air-pressure (Thomsen), and a simple regulator for the electric light (Stöhrer) are also described.—Herr Fröhlich shows the bearing of the principle of conservation of energy on the theory of diffraction.

THE *Rivista Scientifico-Industriale*, (1879, No. 7) contains the following papers of interest:—On some prehistoric discoveries in Sicily, by Prof. Francesco Mangini.—On the lengthening of filiform conductors traversed by an electric current, by Prof. G. Basso.—On the optic rotatory power of quartz and its variation with temperature, by M. Joubert.—On digallic acid, by Prof. U. Schiff.—On some phenomena due to the viscosity of liquids, by Prof. Carlo Marangoni.—On Sargasso seas, by the same.—On Helmholtz' double siren, by the editor.

SOCIETIES AND ACADEMIES

LONDON

Royal Society, February 20 and 27, and April 3.—"On the Reversal of the Lines of Metallic Vapours," Nos. iv., v., and vi., by Professors Liveing and Dewar.

In the first of these experiments the metals were produced by chemical reactions within the tubes, used as before described. They found that cæsium chloride alone heated in glass tubes gave no absorption lines, but cæsium and rubidium chlorides when heated with metallic lithium each showed its characteristic absorption lines. Charred tartrate of cæsium heated in a furnace in a narrow porcelain tube gave very readily the two lines in the blue reversed, and charred rubidium tartrate the two violet lines reversed, but no reversal in any other part of the spectrum. When charred potassium tartrate was treated in the same way, a broad absorption band was seen extending from wave-length about 5,700 to about 5,775. This band was also seen for a short time bright, when the material was put into the tube before it was heated, and the light observed as the tube got hot. It was also seen bright in the induction-spark taken between platinum and potassium in carbonic oxide. Besides this band the vapours from the charred potassium tartrate produced another absorption band in the red, and two more in the blue. None of these absorptions correspond with those seen when potassium is heated in hydrogen, or with known emission lines of that metal, though the first and most conspicuous is near a well-known group of three bright lines of potassium. Charred sugar mixed with carbonate of soda gave only the same absorption as sodium in hydrogen. A mixture of barium carbonate, lamp-black, and aluminium filings gave dark bands corresponding to the bright bands seen when sparks are taken from a solution of barium chloride marked α, β, and δ respectively by Boisbaudran; and at the highest temperature of the furnace fed with Welsh coal a mixture of charred barium tartrate and aluminium gave the barium line wave-length 5535 sharply reversed. Charred strontium and calcium tartrates with aluminium gave no reversals, but with the addition of sodium or potassium carbonate the well-known blue line of strontium and violet line of calcium were reversed. The temperature at which these results were obtained was reached by the use of gas retort carbon as fuel, and was such that iron tubes well coated with fire-clay gave way in a few minutes.

The next experiments were made with tubes bored out of lime and heated at the bottom by a jet of coal-gas and oxygen introduced through a lateral opening. In these, as in the previous experiments, the hot bottom of the tube itself (not an independent light as used by Messrs. Lockyer and Roberts in their experiments with lime tubes) gave the luminous background. In this way the violet line of calcium was reversed, the red line of lithium and the orange and green bands of lime appeared with dark lines down their middles.

A larger series of experiments was made with similar tubes of lime, but with an electric arc introduced through lateral openings as the source of light and heat. In some cases a tube bored in a block of gas carbon was employed, and was then made one of the electrodes. The carbon tubes, however, were found to conduct away the heat, and though they lasted much longer, did not in general succeed so well as the lime tubes. In same cases aluminium was used as a reducing agent, and in others more volatile substances, viz., potassium and sodium carbonates, were used to increase the amount of vapour carried up into the tube; and in others a current of hydrogen was introduced.

Of the calcium lines the violet line (4226) was almost always seen expanded with a dark middle, and the three brightest lines in the indigo were often in a similar condition. The addition of aluminium generally made them appear as dark bands on a continuous background. Of the two Fraunhofer lines H, the more refrangible (K) was the first to appear reversed, and remained so the longer. Other calcium lines reversed were, one in the green (5188), and, much less easily, two in the red (6161, 6121), one more in the indigo (4302), and one in the blue (4877).

In the case of strontium, the well-known blue line was easily reversed, and two lines in the violet (4215, 4077), less easily five lines in the blue (4812, 4831, 4868, 4873, 4895), and, by the aid of aluminium, one in the green (4962). In the case of barium, besides the persistent ray 5535, two other lines in the green (5518, 4933), a line in the blue (4553), and one in the orange (6496), were reversed.

With magnesium the b group were expanded and reversed in an order the inverse of their refrangibility. The other lines of that metal were expanded, but not reversed, and the blue line, 4481, conspicuous in the spark between magnesium electrodes, was not seen at all. This line does not appear in Capron's photographs of magnesium in arc. An attempt to re-introduce it by combining the action of an induction spark with that of the arc in a lime tube failed owing to the conducting power of the hot gases and walls of the tube, and will probably only succeed with a pressure of several atmospheres in the apparatus. The similar disappearance of the cadmium lines 5377 and 5336 was also noticed.

In using potassium carbonate the two extreme pairs of lines, in the violet and red respectively, were readily reversed; less readily the three lines in the greenish-yellow, other two lines in the red (6913, 6946), a group of three in the orange (5353, 5338, 5322), and the least refrangible (5112) of another triplet in the green.

Using sodium chloride, the pair of lines next more refrangible than D were repeatedly reversed, the less refrangible being the first and most strongly reversed, as has also been observed by Mr. Lockyer. A second pair of bright lines usually came out at the same time, like ghosts of the first, on the more refrangible side.

With lithium chloride, the red and blue lines were easily re-

versed, the orange line well reversed, and the green, though with difficulty, distinctly reversed; the violet line, much expanded, showed no reversal. The authors conclude that the green line really belongs to lithium, and not to cæsium, since the blue lines of the latter metal, so easily reversed, never appeared.

In the case of rubidium, the more refrangible of the red lines was seen as a black line on a continuous background, but this background of light did not extend so low as to allow the reversal of the extreme ray of rubidium to be observed.

With metallic indium the two characteristic lines were seen strongly reversed, but no other; metallic gallium also gave its two characteristic lines reversed, the more refrangible being the less strongly so.

Aluminium gave no reversal of any of its lines, except the two between the Fraunhofer lines H. It was noticed that the addition of aluminium to either copper or silver in the lime tubes caused the copper or silver lines, previously predominant, to fade, while the calcium lines came out instead with marked brilliance.

Reviewing the series of reversals which they have observed, the authors remark that in many cases the least refrangible of two lines near together is the most easily reversed, as has been previously remarked by Cornu. Thus, in the case of barium (though there is no very distinct grouping of the lines of that metal), taking the rays in order, the line wave-length 5535 is readily reversed, while that with wave-length 5518 is less easily reversed; the line wave-length 4933 is comparatively easily reversed, whereas that with wave-length 4899 has not been reversed. On the other hand, the line wave-length 4553 has been reversed, but not the line wave-length 4524. In the case of strontium, the lines wave-length 4831 and 4812 have been reversed, but not the line wave-length 4784, and the two lines wave-length 4741 and 4721 remain both unreversed. In the group of five lines of calcium, wave-length 4318 to 4282, it is only the middle line wave-length 4302 which has been reversed. Of the potassium groups of lines wave-length 5829 and 5811, 5802, 5782, the line wave-length 5811 has not been reversed, and of the others the line wave-length 5802 is the first to appear reversed. It is worthy of remark that the first of these lines is faint and the last is the brightest of the group. The group wave-length 5353, 5338, 5322 have been all reversed, but the last of the three (5322) was the most difficult to reverse: it is also the feeblest of the group. In the more refrangible group, wave-length 5112, 5092, 5078, the least refrangible is the only one reversed.

Making a general summary of their results respecting the alkaline earth metals, potassium and sodium, and having regard only to the most characteristic rays, which for barium they reckon as 21 in number, for strontium 34, for calcium 37, for potassium 31, and for sodium 12, the reversals in their experiments number respectively 6, 10, 11, 13, and 4. That is in the case of the alkaline earth metals about one-third, and these chiefly in the more refrangible third of the visible spectrum; the number of characteristic rays remaining unreversed in the more refrangible part of the spectrum being respectively 2, 5, and 4. In the case of potassium they reversed two in the upper third, all the rest in the least refrangible third. These experiments relate to mixtures of salts of these metals combined with the action of reducing agents.

In a table the authors show the relation between their observations on reversals and Young's on the chromospheric lines.

The authors point out that in Young's catalogue the green coronal line (wave-length 5316) is almost as frequently present in the chromosphere as the lines numbered 1 and 82, and D_3 which he suggested might belong to one substance, and they think that the four lines may all belong to the same substance; and they call attention to certain analogies in the ratios of the wave-lengths of these four lines to those of the lines of hydrogen, lithium, and magnesium.

April 24.—"On the Nature of the Fur on the Tongue," by Henry Trentham Butlin, F.R.C.S.

Tongue-fur consists chiefly of (1) *Débris* of food and bubbles of mucus and saliva. (2) Epithelium. (3) Masses which appear at first to consist of granular matter, but which are the glœa of certain forms of schistomycetes. That the last-named of these three is the essential constituent is proved by the fact that the quantitity of the glœa corresponds roughly with the quantity of fur present, and that its position upon the tongue corresponds exactly with that of the fur, both covering the tops of the filiform papillæ, but not usually lying between them.

In order to ascertain the true nature of the glœa, and to obtain it in a purer form, it was cultivated upon a warm stage. Several fungi were discovered, but only two of these were present in every instance, *Micrococcus* and *Bacillus subtilis*; and, as the glœa produced artificially was similar to that existing naturally in the tongue-fur, it is believed that fur is composed essentially of these two fungi. *Micrococcus* developed freely and abundantly, forming large masses of yellow or brownish-yellow colour. *Bacillus* did not develop, but existed in greater or less abundance in all the cases examined. Its development was probably prevented by the presence of other developing organisms, from which it was found impossible to separate it. It appeared to be identical with the *Leptothrix buccalis* of Robin. Although it did not develop under artificial conditions, it is probable that development takes place freely upon the surface of the tongue. Its habitual occurrence there, and the presence of spore-bearing filaments favour this view.

Besides these fungi there were present, more or less constantly, *Bacterium termo*, *Sarcina ventriculi*, *Spirochæta plicatilis*, and a larger form of *Spirillum* (or rather *Vibrio*). *Sarcina ventriculi* was frequently present, and generally developed quickly, forming large masses of a yellow or yellowish-brown colour. *Spirochæta plicatilis* occurred only in two or three of the specimens examined. *Bacterium termo* existed in some of the furs, and twice developed with such rapidity that the whole of the fluid was crowded with these organisms.

The slime between and around the teeth was found to consist of the same fungi as the tongue-fur, but the rods of Bacillus were longer, probably owing to the disturbing causes being fewer.

Physical Society, April 26.—Prof. W. G. Adams in the chair.—Mr. C. V. Boys gave an account of some experiments made by Dr. Guthrie and himself on the subject of Arago's rotation. The experiments were begun with a view to determine if the drag on a copper disk when a magnet is made to revolve beneath it, or on the magnet if the disk is made to revolve above it, could be made use of for determining the velocity of running machinery. They made the magnet revolve, and obtained the angle of deflection of a disk suspended by a torsion thread (the hair-spring of a watch). They found, as Snow, Harris, and others found before, that other things being equal, the drag is directly proportional to the speed, so that if the torsion of the thread could be relied on, and the strength of the magnet did not change, a perfect velocimeter could be constructed. They consider that this method is better than observing the deflection of a magnet over a revolving disk, as in this case they are limited to less than a right angle, and changes in the absolute magnetism of the earth would affect the results. They also determined the effect of change of distance, thickness, diameter, and nature of the disk, &c., their results agreeing with those of former experiments. They observed that the effect of concentric circular cuts was far greater than that of even many radial cuts, and that when radial sectors were entirely separated from each other, the effect was much less than when these were united at the centre. They then experimented on liquids by suspending a sphere or cylinder of the liquid between the poles of a revolving electromagnet, and succeeded in getting a decided and measurable effect. The importance of this is very great, for they have thus a means of determining the conductivity of liquid electrolytes by currents induced in the liquid without the use of electrodes, and without polarisation.—Dr. Guthrie stated that as the push on the liquid is directly proportional to the current quantity, they hope to measure the conductivities of liquids, and connect these to the conductivity of solids through the intervention of mercury. In reply to Prof. Adams Mr. Boys said that the angle of deflection of the conductor had proved to be proportional to its conductivity. Dr. O. J. Lodge suggested that the conductivity of the disks used in these experiments should be determined by plotting out the equipotential surfaces. Dr. Sylvanus Thomson recommended trying conducting jellies in these experiments, and Dr. Guthrie replied that such were being prepared for trial, including the permanent jelly made by dissolving gelatine in anhydrous glycerine at 100°.—Prof. Sylvanus Thomson then communicated five laboratory notes from University College, Bristol. The first related to the source of sound in the Bell telephone receiver. Two theories are now being discussed as to this effect, the molar theory regards the motion of the diaphragm-mass as the source of sound, the molecular theory finds it in the molecular motions of the mag-

netic core of the instrument. Prof. Thomson applied his method of getting magnetic curves with iron filings dusted on gummed glass to this problem. He found that when no currents passed in the telephone the magnetic lines springing from the pole of the magnet are gathered together on the diaphragm opposite over a central region, which is magnetised lamellarly or like a magnetic shell. The rim of the plate beyond this region is, however, magnetised radially, and between these two zones there is a neutral circle. It was remarkable too that the lines of force touching the plate were bent back around this circle, forming a kind of valley. When the current passed in the coil, in a direction so as to reinforce the magnetism, the lines are gathered more closely on the central region of the plate. If the current diminishes the magnetism the lines are, on the other hand, repelled from the plate. The neutral ring is also altered. In the first case it shrinks in size, in the second it expands. A small thick disk is wholly magnetised lamellarly; a disk entirely magnetised radially becomes slightly conical in shape. In the actual telephone the disk is flat at the middle and conical at the edges. As the current varies the diaphragm will assume new nodal lines. Dr. Thompson concludes that the molecular theory is not therefore necessary to account for the speech of the telephone, although it may assist. As confirming this view, he found that with iron rings round a cardboard diaphragm, and an iron centrepiece, the enunciation was good, though the timbre was altered, whereas with radial pieces of iron on the cardboard, the timbre was good but the enunciation bad. In reply to Prof. Adams, Dr. Thompson said that the stronger the magnet the shorter the lamellarly magnetised space became, and that with a thicker disk the neutral ring was not so well marked. Dr. Lodge suggested that the best place for the coil would be in the valley over the neutral ring, which was in an unstable condition. Dr. Thompson next wrote on a saw-blade with a magnet and dusted iron filings on it, which arranged themselves so as to trace the writing. This is usually shown on a steel plate, but a saw retains the virtue for six or eight months. A modification of this experiment, due to himself, consisted in writing on the blade with one pole of a powerful battery, the other pole being connected to the end of the blade. The third "note" recommended the use of fine steel fibres, got by breaking iron gauze of 32 meshes to the inch, instead of iron filings, for exhibiting magnetic lines. The fourth note showed that the lines of force got by filings fixed on cards are magnetic, that of a bar-magnet acting as a magnet. The fifth note explained that solid magnetic "figures" could be got by coating iron filings in shellac to make them light, and floating them in water; or by mixing filings in a soft paste of plaster of Paris, which could be cut into sections on hardening.

Chemical Society, May 1.—Dr. Warren de la Rue, president, in the chair.—The following papers were read:—On the volumes of liquids at their boiling-points obtainable from unit volumes of their gases, by Dr. W. Ramsay. The author has suggested the use of a thin glass bulb filled with the liquid, and heated in its own vapour until expansion ceases, the bulb is then allowed to cool, and is weighed; thus the volumes of many liquids at their boiling-points, "ebullition volumes," has been determined by the author. His results agree closely with those obtained by Kopp; the time required for a determination is half an hour.—On a method of precipitating manganese as dioxide, and its application to the volumetric determination of manganese, by J. Pattinson. Manganese in solution can be completely precipitated as dioxide by bleaching-powder solution or bromine water, if an equal quantity of iron, as ferric chloride, be present. The dioxide is then dissolved in dilute sulphuric acid, reduced by standard ferrous sulphate and titrated with bichromate.—On the determination of nitric acid as nitric oxide by means of its action on mercury, by R. Warington. In this well-known process of Crum and Frankland the author has found that the removal of the chlorides is unnecessary, and that small quantities of organic matter, except cane sugar, do not interfere with the results.—On a new class of colouring-matters, by Dr. O. N. Witt. By oxidising a mixture of metatoluylene diamine and dimethylparaphenylendiamin in aqueous solution, the author has obtained several new colouring-matters, toluylen blue, violet, pink, &c.

Institution of Civil Engineers, April 29.—Mr. Bateman, F.R.S., president, in the chair.—The first paper read was on street carriageway pavements, by Mr. George F. Deacon, M. Inst. C.E.—The second paper read was on wood as a paving material under heavy traffic, by Mr. O. H. Howorth, Assoc. Inst. C.E.

EDINBURGH

Royal Society, April 21.—On the anatomy of the northern Beluga (*B. catodon*) compared with that of other whales, by Morrison Watson, M.D., and Alfred H. Young, M.B., of the Owens College, Manchester.—This paper contains a complete account of the visceral anatomy of *Beluga*. In connection with the larynx, the existence of pouches similar to those previously described by Murie in Risso's Grampus is pointed out. These pouches undoubtedly correspond to the large laryngeal air-sac of the whalebone whales; both are regarded by the authors as homologous with the ventricles of Morgagni of other mammals, and not, as considered by previous anatomists, with the well-marked air-sacs met with in several species of quadrumana.

BOSTON, U.S.A.

American Academy of Arts and Sciences, April 9.—Hon. Charles Francis Adams in the chair.—Prof. Benjamin Peirce presented a paper on the meteoric constitution of the solar system, in which the existence of a meteoric shell outside of the planetary system is maintained. The meteors, in falling from this shell, would be subject only to the attractions of the sun and planets. The motions of the larger meteors or comets were discussed, and some remarkable agreements of observed facts with the theory were shown.—Prof. Pickering described a new form of transit instrument for measuring the light of the stars. Much of the time spent when using other photometers in identifying the object is thus saved. The stars are compared directly with the pole-star, and the variations of an artificial star are thus avoided. At the Harvard College Observatory the measurement of the light of about 4,000 stars of the sixth magnitude and highest, has been undertaken with this instrument. Each star will be observed on three nights, and two sittings will be made each evening.—A paper on the action of bromine on substituted toluols was presented by Prof. C. Loring Jackson and Mr. A. W. Fields.—Mr. W. W. Jacques, of Johns Hopkins University, Baltimore, presented the results of an investigation into the distribution of heat in the spectra of various sources of radiation. The distribution of heat in the spectrum of a solid or liquid source of radiation was found to be nearly independent of the temperature of the source. Dr. Draper's conclusion that "It necessarily follows that in the spectrum any two equivalent series of undulations will have the same heating power, no matter what their actual wave-length may be," was found to be not correct.

CONTENTS

THURSDAY, MAY 15, 1879

THE VICTORIA UNIVERSITY

THE movement for founding a new university in the north of England has progressed considerably since the question was discussed in these columns in July, 1876. It has now shaped itself into a final memorial to the Privy Council, which will be presented to the Lord President by a peculiarly powerful deputation this very day. Let us hope that the reply will be a favourable one, believing as we do that the educational welfare of the country demands an increase in the number of its universities. It may be desirable to say a few words about the progress of this movement.

On July 20, 1877, a memorial addressed to the Privy Council was presented to the Lord President praying that Her Majesty should be advised to grant a charter to the Owens College, Manchester, to be thenceforth called the University of Manchester, with power to grant degrees in Arts, Science, Medicine, and Law.

A slight modification of the original programme has now been made with the view of providing more effectually for two of the objects contemplated in the former memorial, viz. (1) for an ample and sufficient control over the proposed university, as a national place of education and learning, by the Government of the country; and (2) for the incorporation in the proposed university, on equitable terms and on satisfactory conditions, of other colleges besides the Owens College. This is not the place in which to discuss in detail the constitution proposed. We may, however, remark that Owens College is to be named in the charter as the first college of the new university, and that Manchester is to be the local centre of this institution.

In consequence of this modification the support to the memorial will be, we believe, even more powerful than that formerly given and may be taken as fairly representing the opinion of two great counties in the north of England. The Lord President has consented to receive simultaneously two deputations, one headed by the Duke of Devonshire, president of the Owens College, and the other from the Yorkshire College, Leeds, headed by the Archbishop of York.

Since this scheme has been before the public the most persistent objection urged against it has been advanced by those who maintain that the teaching and examining functions of a university should be perfectly distinct. It may be worth while to discuss this objection from two points of view, endeavouring to ascertain in the first place what is the present practice in this country of the existing universities, and then to find what course is best in principle.

Let us begin with the London Examining Board, which has no teaching staff connected with it, and ask ourselves whether its machinery secures an absolute separation between the examining and teaching elements. There can only be a negative reply to this question. The Senate of the London Board frequently select examiners who are teachers in one of the two London colleges or in Owens College, Manchester; that is to say, in institutions which send numerous candidates to the London examinations.

The result of this system must inevitably be that (without any blame being attributable to any one) the pupils of such an examiner have an advantage over other candidates whose teachers are not so represented. Thus, with respect to this Central Board, only a partial separation between the teaching and examining elements has been found practicable, and a very questionable advantage has been given to certain candidates in the examinations.

Let us next take Cambridge, as representing one of the great English Universities. Here it is the practice that the Committees who arrange the branches of study for the various examinations should consist very largely of professors and lecturers, who likewise form a large portion of the examining body. Occasionally a private tutor is chosen as an examiner, in which case, for a few months preceding the examination, he is expected or required to give up those of his pupils who are coming forward as candidates.

Now, while this system is infinitely preferable to that of the London Board, yet even here the former pupils of the private tutors who have been chosen examiners must, we think, have a small advantage over the others, which is, however, reduced to a minimum inasmuch as the Boards of Examiners for a subject consist of four men at least. In the Queen's Colleges, Ireland, the practice is different. Here there are four colleges, which form together one University, and it is, we believe, the custom that, in conducting examinations for degrees in any college, the professors of that college should associate with themselves an outside element consisting of certain professors from the other colleges of the same University.

The practice in Scotland is somewhat similar to that in Ireland, the chief difference being that, whereas in Ireland the external element consists, we believe, of members of the teaching staff of one of the other colleges, in Scotland it consists of graduates of some one of the Scotch universities who are not engaged in university teaching in Scotland. Should the Victoria University succeed in obtaining a charter, its practice will be very similar to that in Scotland, and it must, we think, be owned that one advantage of this system is that by it all candidates are placed upon precisely the same footing.

All this, however, might be freely allowed by those who advocate an entire separation between teachers and examiners. They might reply that any such advantage is more than overborne by the manifest tendency to lower the standard of efficiency when the teacher is permitted to take any part in the examination of his pupils.

This subject has been very fully discussed in a recent report of the Royal Commissioners appointed to inquire into the universities of Scotland, one of whom was the well-known author of the "herring-brand" comparison. The following is a quotation from this report (page 49).

"The examination of the students of a university for their degrees by the Professors who have taught them, is sometimes spoken of as an obvious mistake, if not abuse: but those who are practically acquainted with university work will probably agree with us that the converse proposition is nearer the truth. In fact, it is hard to conceive that an examination in any of the higher and more extensive departments of literature or science can be conducted with fairness to the student, unless the examiners are guided by that intimate acquaintance with the extent and the method of the teaching to which the learner has had access, which is possessed only by the

teachers themselves. . . . The admirable influence which the Scottish universities have hitherto exerted upon the people of the country has been due not only to the prolonged and systematic course of mental discipline to which their students have been subjected, but to the stimulus and encouragement given to inquiring minds by distinguished men who have made the professorial chairs centres of intellectual life; and we cannot think it desirable that any such changes should be made as would tend to lower the universities into mere preparatory schools for some central examining board."

We are gratified to think that the sentiments which we expressed in these columns nearly three years ago should have received the sanction of such high authorities. As the subject is one of great importance, our readers will perhaps allow us to repeat the objections we then raised to the establishment of a Central Examining Board (see NATURE, vol. xiv. p. 255):—

"The Calendar of the Central Board must inevitably embody only the best-known and most widely-diffused results of knowledge—not that which is growing and plastic, but that which has already grown and hardened into shape—the knowledge, in fact, of a past generation which has become sufficiently well established to be worthy of this species of canonisation. A very powerful inducement is thus offered to the professors of the various colleges to teach their pupils according to this syllabus, and a very powerful discouragement to attempt to alter it. They may be men of great originality and well qualified to extend and amend their respective spheres of knowledge, but they have no inducement to do so. . . . . It is the old and time-honoured custom of killing off the righteous man of the present age in order the more effectually to garnish the sepulchres of his predecessors. Our readers are well aware that the natural philosophy course has changed its character very greatly of late years, and that for this we are much indebted to Professors Sir W. Thomson and P. Guthrie Tait. But could these men have done this under the system of a Central Board? If they had succeeded it must have been, as Galileo succeeded, against the attempt made by the ruling authorities of his day to stop his voice and strangle his originality."

It has always been a source of infinite amazement to us that a single man of eminence should come forward to advocate the gigantic apparatus for cram implied in a Central Examining Board.

May the day be far distant when the rising generation shall all be required to feed upon such rations! One is tempted to think that the advocate of this system must surely have suffered a transmutation similar to that which overtook Bottom, who, in consequence, entertained quite original notions on the subject of food. "I could munch," said that worthy, "your good dry oats. Methinks I have a great desire to a bottle of hay; good hay, sweet hay, hath no fellow."

ORGANISMS IN THE BLOOD, AND THE GERM THEORY

The Microscopic Organisms found in the Blood of Man and Animals, and their Relations to Disease. By Timothy Richards Lewis, M.B., Army Medical Department, Special Assistant to the Sanitary Commissioner with the Government of India. (Calcutta, 1879.)

WE have here in a small illustrated work an able critical *résumé* of some of the most important facts previously known on the subject together with others not hitherto published, tending not only to increase our knowledge, but also to throw light upon the general question of the relations of the microscopic organisms found in the blood to disease.

Nearly two-thirds of the work refers to the existence in the blood of vegetal organisms of the type of Bacteria, Bacillus, and their allies, while the remaining third relates to the existence in this situation of animal organisms. We have in this latter part a brief but interesting history of what is known concerning the existence of Nematoid hematozoa in the lower animals, and also of what has been learned concerning the embryos of the *Filaria sanguinis-hominis*, first discovered by the author in 1872, in the blood of persons suffering from Chyluria.

It seems evident from the account here given that we have still almost everything to learn as to the source and parental forms of these embryo Nematoids found in the blood of man. The hypothesis of Manson concerning the part played by mosquitos as intermediate hosts (within which some of the embryos swallowed may undergo development, and from the bodies of which parent-forms, capable of infecting man, may find their way into drinking water) seems, from the careful observations made by Lewis, to be rendered more than doubtful. The relations of these organisms to the morbid conditions with which they are associated are, indeed, full of the most puzzling difficulties. It is somewhat doubtful whether the mature form of this helminth has yet been discovered, notwithstanding the observations of Dr. Bancroft in Australia, and of Dr. Lewis himself (as referred to on pp. 85-89). The fact of the persistence of the envelope of the ovum as a diaphanous sheath, surrounding each of the young embryos found in the blood of man, would seem to the writer strongly to suggest the probability that the embryos in question have been liberated at once into some portion of the vascular system, rather than that they have entered it from without by penetrating its walls. If such a process of struggling through tissues were to take place, their thin diaphanous envelopes would stand a good chance of being torn and left behind.

Nematoid helminths have long been known to occur in the blood of many birds, and Dr. Lewis says: "I have examined a considerable number of the ordinary Indian crow (*Corvus splendens*), and have found that the blood of nearly half of those which have come under my notice have contained embryo hæmatozoa of this character. Sometimes they are in such numbers as to make it a matter of surprise how it is possible that any animal can survive with so many thousands of such active organisms distributed throughout every tissue of its body. The birds did not appear to be affected in the slightest degree by their presence. In their movements they are very similar to the nematoid embryos found in man; they are, however, considerably smaller, and manifest no trace of an enveloping sheath."

Again, observations made many years ago by MM. Gruby and Delafond went to show that 4 to 5 per cent. of the dogs in France harboured microscopic nematodes in their blood; Lewis ascertained in 1874 that more than a third of the pariah dogs of India are similarly affected, whilst Dr. P. Manson has shown that this kind of parasitism affects at least an equal proportion of dogs in China. The embryo nematodes belonging to dogs of these

different countries seem to agree with one another in all their characters. It is important to note that their presence is not associated with the existence of any definite disease. The dogs harbouring such parasites are outwardly indistinguishable from others which have them not. Strange as this may seem, it is also strange that the mode in which the embryo organisms gain access to the blood is still involved in great obscurity. It is true that, by several observers at different times, thread-like mature nematodes (*Filaria immitis*) have been found in more or less abundance in the right chambers of the heart of the dog. These have been found to be extremely common by Dr. Manson in China, and might therefore naturally enough be considered as the source of the multitudes of embryo nematodes found in the blood of these animals. But if true for China, it ought also to hold good for India; yet Dr. Lewis says:—"It seems somewhat strange that, notwithstanding the marked prevalence of embryo hæmatozoa, the *Filaria immitis* has not, so far as I can learn, been recognised in India. I have often searched specially for it but in vain. The only mature parasite which appears to affect the circulatory system of dogs in this country is the *Filaria sanguinolenta*, a description of which, together with an account of the pathological changes which are caused by it during its development in the walls of the aorta and adjacent tissues, was published by me in 1874."[1] But then, the same writer adds:—"Notwithstanding the circumstance that this is the only mature helminth which I have found associated with the embryo hæmatozoa of India, I cannot believe that there is a genetic connection between them, for it frequently happens that the mature worm may be present in abundance unassociated with blood embryos of any kind, and sometimes it is found that the latter exist without any trace of the former."

What has been said above suffices to show the very considerable gaps in our knowledge concerning the life-history of the Nematoid hæmatozoa of man and animals, and also the tendency so frequently met with among some observers to bridge these gaps by unsatisfactory explanations deduced from a too-narrow survey of the facts—a perennial source of error peculiarly common in regard to this class of questions.

Of the protozoa referred to as being found in the blood of the lower animals the newest and perhaps the most interesting are those now first described by the author as existing in that of Rats. Being directed by the Indian Government to make observations on the spirillum occurring in the blood of patients suffering from the Bombay fever, the author says: "Whilst doing this I had occasion to examine the blood of a considerable number of animals, and eventually (July, 1877) detected organisms in the blood of a rat which, at first sight, I took to be of the nature of vibrions or spirilla." The organisms, of which figures and photographs are given, are each of them provided with a long and very distinct flagellum, though otherwise they are not very different in appearance from some bacilli. Subsequent observations showed Dr. Lewis that whilst such organisms do not seem to exist in the blood of mice they are to be found in two species of rats, viz., *Mus decumanus* and *Mus rufescens*. Concerning their prevalence and pathological significance in these animals, he says:—"I have examined the blood of a great number of rats for the purpose of ascertaining what proportion of them contains these organisms in their blood, and find that of those specially examined for this purpose, their existence was demonstrated in 29 per cent. Sometimes, however, the numbers detected were very few, not more than one or two in a slide, but in the greater number of cases they were very numerous, every slide containing several hundreds. . . . . With regard to the health of the rats in which these flagellated organisms were detected, there was nothing to suggest in any way that they were less healthy than others not so affected, and I have repeatedly kept rats for a considerable time for the purpose of observing whether any special symptoms would be manifested. . . . . When it is considered that thousands of active beings of this character can exist in the blood without in any appreciable manner affecting the health of their host; and when it is further considered that these organisms must consume at least as much, if not far more, oxygen than bacteria, bacilli, and spirilla, it becomes difficult to understand how it comes about that, to a like action on the part of the latter is ascribed the asphyxia and the other morbid conditions which characterise death from splenic disease and allied affections." Such a view has been put forward by MM. Pasteur and Joubert, though it is well known, and has been pointed out by Virchow amongst others, that the proportion of bacilli in the blood at autopsies, bears no sort of relation to the severity of the disease previously existing in the persons under examination.

But it is in regard to these vegetal organisms existing in the blood of man and some animals that the larger part of Dr. Lewis's memoir refers. He evidently entertains a clear view of the principal phenomena to be considered in reference to this part of the subject, and exhibits a rare absence of a tendency, which is unfortunately but too common, to slur over fundamental difficulties standing in the way of the acceptance of the "Germ Theory of Disease"—or the "Doctrine of Contagium Vivum" as it is sometimes termed. In addition to acute criticism Dr. Lewis has made known some very significant and important new facts.

After referring to the generally received view that organisms of the bacterium or bacillus type do not exist to any recognisable extent in the blood of healthy animals, and to the experiments made some years ago by Dr. Douglas Cunningham and himself, which showed how quickly, after such organisms had been purposely introduced into the blood of healthy animals, they disappeared therefrom, he says:—"It may be safely affirmed that their presence in appreciable numbers is, judging from experience, incompatible with a state of perfect health." The case in regard to these microphytes is, therefore, different from what has been stated to obtain with the animal organisms before mentioned, which may swarm in the blood of creatures who are in other respects quite healthy.

One or other of such microphytes has been found to be generally present in *charbon* or *splenic fever*, and in *recurrent fever*. M. Pasteur has of late maintained that *septicæmia* is also characterised by the existence of such organisms in the blood during life; and to this list Dr. Klein adds the so-called *typhoid fever* of the pig.

[1] "The Pathological Significance of Nematode Hæmatozoa."

It is impossible to follow the author through his discussion (pp. 11-34) of the leading facts regarding the connection of microphytes with the diseases above mentioned, but we may briefly consider the question of their causal relation to the morbid conditions with which they are severally associated.

If the organisms of this type commonly met with outside the organism are not specifically injurious when introduced into the bodies of higher animals (and this has been abundantly proved and is commonly admitted), then, the notion that those met with in certain diseases are causes thereof, must necessarily be associated with the belief that they are organisms in some way distinct from the common forms. And this is generally the case; as Dr. Lewis says:—"All the advocates of the germ theory, with very few exceptions, maintaining that the particular organism, in the particular disease in which they are specially interested is wholly distinct from all others."

This is a position which is far from having been proved, however, and is by itself an extremely questionable doctrine. There are no real morphological characters separating the bacillus of splenic fever or of "pig typhoid" from the bacillus of hay, of urine, and of multitudes of other organic mixtures. So far as morphological characters are concerned, this is practically admitted; but then it is contended by Cohn and others that difference in "physiological property" may afford sufficient ground for the establishment of specific distinctions, even in the face of morphological similarity. This is a rather hazardous doctrine, and requires to be advanced with the greatest caution. To what extent in the vegetal and in the animal scale is it to hold good; or is it to be a distinctive character confined to the most protean and highly modifiable of all organisms? On the one hand we find such an authority as Prof. Cohn of Breslau supporting the notion; on the other a scarcely less weighty authority, Prof. Nägeli of Munich, declaring that he is unacquainted with any facts really supporting such a view. He says: "I have during the last ten years examined some thousands of different forms of fission-yeast cells,[1] but (excluding *Sarcinæ*) I could not assert that there was any necessity to separate them into even two specific kinds."

Bacilli, born and bred in the midst of the blood and tissues of a diseased animal, might have certain slight molecular differences impressed upon them, by reason of which they may tend during their nutritive life-processes to secrete a poisonous chemical principle—just as the common putrefactive bacteria are known to do—and it may thus happen that the progeny of such organic units born in morbid fluids or tissues, are capable of setting up morbid processes in the animal economy such as do not follow from the addition to it of bacilli nurtured in a bland hay infusion. This is a mere surmise, thrown out as a view which may be found by some to be easier of acceptance provisionally than the notion that, among the most variable of organisms, from a morphological point of view, several "species" present themselves under precisely the same form, and that identity or difference of "species" is to be judged by the mere effects produced by their invisible molecular activities.

Further, it should be borne in mind that the association between the organisms and the diseases in question is not absolutely constant, nor is the severity of the disease in the least proportionate to the abundance of the organisms found in the animals affected. Speaking of recurrent fever Dr. Lewis says:—"Whereas spirilla could generally be detected in cases of fever of this kind, nevertheless cases every now and then occurred in which perfectly competent observers failed to detect them in the blood from first to last, and this too in cases not a whit less severe than those in which the organisms abounded and which were under the care of the same observers during the same period." This was the experience of Dr. Lewis himself.

Again, in regard to the same disease, the assumed cause will not operate when it is placed under the most favourable conditions—conditions in which it is scarcely conceivable that the organisms should fail to operate were they the veritable causes of the disease. Alluding to well-known experiments made by Obermier, the discoverer of the spirilla of recurrent fever, our author says:—"The inoculative experiments which he undertook, consisting of the injection of spirillum-blood of fever patients into the veins of dogs, rabbits, and guinea-pigs proved abortive, nor was there any effect produced by the injection by means of a subcutaneous syringe of small quantities of such blood into the bodies of healthy persons." Others likewise failed to reproduce the disease by similar means, though one observer states that he had been more successful in thus setting up the disease—irrespective, however, as he says, of the presence of spirilla in the blood with which inoculation was made.[1]

What manner of cause then is this, whose effects take place in its absence, in no corresponding ratio when present, or whose presence is followed by no effect at all? One of a strange order, truly!

But now we come to a great difficulty, an all-important matter, which in its turn has to be explained by those who cannot accept the notion that the microphytes to which we have been referring are causes of the diseases in question. Those who hold the opposite notion will naturally say to the opponents of the germ theory—But, if these organisms are not to be regarded as causes of the disease how do you account for their very frequent presence in association therewith?

Communicable or contagious diseases constitute a large class, and those in association with which microphytes have been found form only a small minority. Seeing the multitudes of observers who have been searching for them for years past in the blood of persons suffering from such affections as scarlet fever, small-pox, measles, and others, the chances that any such organisms will be found in association with these diseases may be said to be diminished to a minimum. Therefore, in so far as concerns the very frequent occurrence of organisms in the blood of persons suffering from recurrent fever, splenic fever, and some other maladies, it would be perfectly consistent (if conformable with other evidence) to regard such organisms as quasi-accidental products or epi-phenomena of the diseases in question.

If we accept the doctrine of Pasteur, Lister, and others to the effect that the blood of all healthy animals is invariably free from such microphytes, the appearance of

[1] That is, the *Schizomycetes*, in contradistinction to the true yeast-cells.

[1] The relations of this spirillum to other known spirilla is discussed at pp. 46-48.

organisms in the blood as epi-phenomena in the course of certain diseases can scarcely be explained except by the supposition that archebiosis or heterogenesis (one or both) have taken place in their altered blood, or in blood and tissues simultaneously.

This the present writer long ago pointed out, and he strongly insisted upon it in a paper published about eighteen months ago,[1] but which does not seem to have reached Dr. Lewis before the printing of his present work. Attention was there specially called to the fact that organisms speedily appeared in the blood of previously healthy animals or of human beings suddenly killed, in such situations and under such conditions as to make it almost impossible to account for their presence except by the occurrence of one or other of the processes above mentioned, giving rise *in situ* to a new birth of such microphytes. Organisms can, in fact, be made to appear at will (as Lewis and Cunningham, as well as Sanderson, had shown) in localised parts of previously healthy organisms by lowering the nutrition in certain ways of such parts of the body, *i.e.*, by either tying the artery supplying the part with nutrient fluid, or by subjecting the part to the influence of some germless chemical irritant. On the other hand, when the nutrient processes throughout the body are checked by the death of the animal, the production of microphytes, which was before local, now, as the writer has several times pointed out, becomes general.

Let the germ-theorists look to these facts and give us a better explanation if they can; because in the cases above referred to, organisms appear in tissues which they themselve have proclaimed to be germless, and in blood which they have declared to be free from all antecedent signs of microphytes.

The facts of the latter order have been distinctly confirmed by Dr. Lewis. He says: "Rats were obtained, killed by means of chloroform, and set aside from three to twenty-four hours or longer, according as the temperature of the atmosphere was high or low. The result proved that almost invariably bacilli were to be found in the blood, in the spleen, and in other organs."

It appears, however, and the fact is one of considerable significance, that when death takes place in certain modes (as by poisoning with carbonic acid or carbonic oxide), organisms have a still greater tendency to appear in the blood and that they manifest themselves with surprising rapidity.

A man who was sent to seek for rats, having found, "That he could procure more than could be accommodated in the cage which he had brought with him, he obtained a large earthen vessel, transferred twenty-seven rats into it, and tied a piece of cloth over the mouth of the vessel. As may be supposed, the rats had perished before he got home—all except one. . . . I examined the blood and the spleen of twenty of these rats within about six to eight hours of their having been caught, and found in each case that there were innumerable bacilli present, in every way morphologically identical with *Bacillus anthracis*.[2] In some of the cases the number was astonishing. They were present chiefly in the form of rods, but here and there some were seen to have grown to such a length as to cover two fields of the microscope. . . This experience tends to give support to the statement made by M. Signol before the French Academy, to the effect that motionless bacilli identical with those found in charbon, will be found in sixteen hours, or less, after death, in the blood of animals which have been asphyxiated by means of a charcoal fire."

Dr. Lewis shows that these organisms which make their appearance within the bodies of animals so soon after death are not only morphologically indistinguishable from *Bacillus anthracis*, but that they go on, under suitable conditions, to the so-called "spore" formation in precisely the same manner. The characters of these organisms under different conditions are well shown in Pl. I.

But if mere modes of dying influence the quickness with which such organisms appear in the body after death, it is not inconsistent to suppose that they may in certain cases—that is, in association with certain morbid processes—be much more prone than in others to show themselves as epi-phenomena. And this seems to correspond with what actually occurs; in many contagious diseases, as above stated, such organisms seem to be absent, in a few they show themselves, and that by far the most frequently in cases where death is already pretty closely at hand.

Referring to the bacilli met with in malignant pustule (charbon), septicæmia, and the so-called "typhoid fever," in the pig, horse, and other animals, Dr. Lewis says: "It may be confidently stated that they are never to be detected in the earlier stages of the disease, but only at a brief period before and after a fatal termination. To my knowledge they have never been found in the blood of animals which have subsequently recovered; they have always been recognised only as one of the concomitants of impending dissolution. This is undoubtedly the case so far as the two diseases first cited are concerned."

Those who are the warmest advocates of the germ-theory of disease—a doctrine resting on sufficiently unstable foundations—are not always cautious or discreet in the way they speak of others who lean to a belief that the organisms met with in association with disease are mere epi-phenomena, often produced within the body by a process of heterogenesis. Yet the latter interpretation, so far as present knowledge goes, seems to the writer essential for the explanation of our power to determine, at will, the presence of microphytes in the germless tissues or germless blood of previously healthy animals.

Antiquity of Orchids

I HAVE been struck by a most cogent remark of Mr. Wallace's in his review of Mr. Allen's "The Colour Sense" (NATURE, vol. xix. p. 501), viz., "But surely in orchids the perianth

more highly specialised than in any existing flowers whatever; and if we take into account the world-wide distribution of these plants, their intense richness in genera and species, and their wonderful complexity of structure, we must consider them as among the most ancient instead of the most recent of flowers."

Without venturing any opinion as to the geological age to which the development of this wonderful order of plants must be traced back, it seems to me that there are some classes of facts concerning our native European species which support the conclusion that their existence in their present specific characters must date from a very remote time.

1. It is an important fact that out of fifty species of orchids enumerated in Garcke's "Flora des deutschen Reiches" (exclusive of the Bavarian Alps, which possess two or three more species), not less than forty-one occur in the British Isles (besides *Neotinea intacta* and *Spiranthes romanzoviana*, not found in Germany), a proportion considerably exceeding that of phanerogams generally. Now, as it seems scarcely credible that orchids should possess means of transportation across the sea in preference to other plants, we must conclude that they inhabited the British Isles before their separation from the Continent, which involves that they occupied stations near the present coasts of Germany or France previous to a great deal of plants that reached these coasts only subsequently to the formation of the Channel. These conclusions are rather strengthened by the fact that several orchids are by no means frequent in Germany, and very rare and local in Britain, which proves that their occurrence is not to be accounted for by favourable present conditions, and even renders it probable enough that some of the species found in Germany, but not in Britain, may in the latter country have become extinct in times not very long ago.

2. Notwithstanding the light so plentifully thrown on the significance of the floral peculiarities of our orchids by Mr. Darwin's admirable investigations, there remain some species whose relations to insects, although evidently of a most specialised nature, are yet very little understood. Such seems to be the case with Himantoglossum and with Ophrys. It is therefore to be suspected that the adaptations of these species may point to insects no longer existing in our countries. However, I should not insist on this point were it not somewhat connected with the following:—

3. It has been observed by Mr. Darwin that "the frequency with which throughout the world members of various orchideaceous tribes fail to have their flowers fertilised, though they are excellently constructed for cross-fertilisation, is a remarkable fact." And further on Mr. Darwin alludes to the unknown causes which lead to the destruction of seeds or seedlings, forming a check to the multiplication of orchids. Indeed, with many of our native species, though abundantly fertilised, multiplication by seeds is evidently but a rare exception to the general rule of propagation by side-bulbs, *i.e.*, mere individual persistence. Thus the wonderful contrivances for cross-fertilisation point back to different conditions of life in the past, under which their function must have been much more active and important than it is now.

There may, I think, be found analogous cases in very different quarters of the vegetable kingdom; for instance, the frequent reduction of the peristome of mosses to mere rudiments is probably connected with actual preponderance of vegetative propagation over propagation by spores. In the orchids, too, there are already perceptible some traces of a regressive change of the apparatus for cross-fertilisation (for instance, in *Ophrys apifera*), as will be inevitable in the course of ages, whenever specialised structures are no longer sustained by active function, leading to their reproduction under the agency of natural selection. Perhaps such regressive change goes on more slowly in cases of merely vegetative propagation.

Finally, I may allude to the fact of our native orchids belonging to very different groups of the order, and this enhances the argument for antiquity, based on their geographical distribution. D. WETTERHAN

Freiburg im Breisgau, May 10

Barometric Pressure and Temperature in India

IN order to satisfy myself as to whether some of Mr. Broun's conclusions (NATURE, vol. xix. p. 6) held good when inland stations were included in the comparison, I recently examined in detail the pressure and temperature oscillations at fifty-one stations in the Indian peninsula, computed from the means given in Mr. Blanford's "Indian Meteorologist's *Vade Mecum*." As these stations represent every part of the country, the results afford a basis for deduction of sufficient extent to be reliable.

An inspection of these shows (1) that the range of pressure-oscillation corresponding to 1° F. *varies* very much at different places, its extreme limits being 0·002 in. at Leh, and 0·032 at Vizagapatam, and its mean value for all the stations 0·017 in.

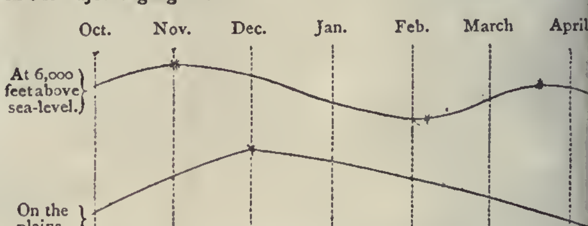
2. That on arranging the stations in order of elevation, it is plain that this variation is partly related to the height above sea-level, being least at Leh (11·538 feet), the most elevated station, and increasing from thence downwards at the mean rate of about 0·002 in. for every thousand feet of descent. The numerous deviations from this rule, however, especially at the lower elevations, make it evident that other factors operate besides height, such as distance from the coast and latitude. Though no rigorous comparison with these has as yet been made, a mere inspection of the results is enough to show that proximity to the sea, and, therefore, *ceteris paribus*, greater humidity is associated with a greater barometric oscillation corresponding to 1° F.[1]

3. That when the element of horizontal space alone is considered, the pressure oscillation increases with the temperature oscillation, but not very regularly, and that while this relation holds pretty generally in the plains, it disappears altogether at the more elevated stations, or, when the element of vertical space is introduced.

Now while the pressure ranges generally decrease pretty regularly as we ascend, the temperature-range remains about the same at different heights. The decrease, therefore, in the pressure-oscillation for 1° F., noticed in the case of elevated stations, must plainly be solely due to the contraction which takes place in the pressure-range.

The diminished mass of atmosphere above the more lofty stations, doubtless in a great measure accounts for this diminished amplitude of the oscillation. Another important factor, however, in this result, must not be overlooked, viz., the *double* annual oscillation of monthly mean pressure which takes place at stations of 6,000 feet and upwards in height, apparently throughout India, the effect of which is sensibly to diminish the absolute annual range of pressure-oscillation at these heights.

In fact, the curves representing the mean monthly barometric pressure in the winter at the hills, and on the plains respectively, may be taken to approximate more or less in character to those in the adjoining figure.



Pressure Curve (the critical points are marked with asterisks).

Now as the pressure on the plains is made up of the pressure at a height of 6,000 feet + the weight of the stratum of air between, it is evident that the latter must reach its maximum somewhat later than December. Moreover, as the winter depression at the highest stations is considered to be caused by the inrush at their level of the saturated anti-monsoon at this season,[2] the direct effect of the cold of this season in increasing the density, and hence the pressure of the atmosphere, will only be felt in the stratum of air between them and the plains. It is im-

[1] This relation appears to be independent of that due to elevation, with which it might be thought identical, owing to the general decrease in the heights as we travel seawards. The following stations which have nearly the same elevation, but are at widely different distances from the sea, will show this very clearly:—

	Height above sea in feet.	Bar oscillation for 1° F.
Lucknow	369	0·017
Sibsagar	332	0·028
Difference ...	37	0·011

Now if the approximate rule for difference of elevation already mentioned, viz., a decrease of 0·002 inch in the bar-oscillation for 1° F. for every 1,000 feet of ascent be applied in this case, the decrease at Lucknow should evidently be inappreciable. As it is, however, it is of very considerable magnitude.

[2] *Vide* "Indian Meteorologist's *Vade Mecum*," by H. F. Blanford, p. 75.

portant, therefore, to find out when the maximum average density, or what is practically the same thing, the maximum barometric weight of this stratum, occurs, and more especially to see whether it coincides with the epoch of minimum temperature, which, as a rule, occurs in January throughout India.

The following table, in which I have calculated the mean monthly barometric weight of such a stratum in different part of the country, will show that the maximum invariably occurs in January, that is to say, it *coincides* with the epoch of minimum temperature. Two bars placed underneath a figure indicate the maximum pressure or weight of the year; one bar, the secondary maximum at the hill-stations in the spring.[1]

* To avoid repetition, I have merely given the decimals after the first column. In every instance of omission the last prefixed integer is to be supplied.

Without going any deeper into the matter, it must, I think, be generally admitted that the preceding facts not only dispose of Mr. Broun's objection to the idea that pressure and temperature are related, because the epoch of maximum atmospheric pressure on the plains of India generally *precedes* that of minimum temperature, but also show how abortive any attempt to base inductions regarding a secular variation in solar heat, upon the results of comparing the annual range of monthly mean pressure, or even the mean annual pressure, for a number of years in succession in different parts of India, must necessarily prove, unless they be duly taken into consideration.

With reference to Mr. Broun's conclusions alone, the following modifications should be attached, according to the results of my investigation.

1. The annual oscillations of monthly mean pressure and monthly mean temperature bear an exceedingly *variable* ratio to one another in India, such variation being a function partly of the altitude, and partly of the distance from the coast.

2. Non-coincidence of the critical epochs of monthly mean pressure and temperature, cannot be rigorously employed as an argument against the hypothesis, hitherto generally accepted, of a causal connection between them.

E. DOUGLAS ARCHIBALD

Insect Galls Buds

INSECT galls are held to be "excrescences"; a "diseased condition of vegetable tissue"; and they are supposed to result from the "injection of a fluid," or from some "secretion." The student may most easily begin an investigation of galls with the dissection of those produced by the turnip weevil (*Curculio pleurostigma*) on the bulb of the Swede. The roots of Swedish turnips are frequently covered with hundreds of irregular spherical warts, from ·03 to ·75 of an inch in diameter, growing either singly or crowded together in clusters. These warts are regarded by M. Woronin (*Plasmodiophora brassicæ*, Pringsheim's *Jahrb.* xi. B. p. 548) as resulting from the fungus which he has discovered to be the cause of club-rooting in cruciferous plants. I believe that on this point M. Woronin has been misled. The true clubs produced by his fungus are entirely distinct from these root-nodes. Under favourable conditions the root-nodes have been found to give rise to tufts of leaves; a fact which I can confirm by many examples presently growing in my possession. Dissection of these nodes, on Swedes, shows that they contain none of the plasma and spores which constitute the bulk of the true clubs. They are, in fact, tuberculated buds arising directly from medullary rays in the root to which they are attached. These can be traced through the enveloping parenchyma into the nodes, where they are seen to give rise to masses of contorted and branching leaves. The nodules within the bark of the beech, hazel, and other trees, are of the same character as those on the turnip. The medullary nexus of these nodules sometimes comes straight from the centre of the tree into the node, and sometimes runs along like a cord under the outer layers of the bark, entering the node by the end.

Let a dissection now be made of one of the weevil galls on the bulb of the turnip. The second or third slice will show the outer foliations, exactly similar to those of the root buds. When the centre has been reached, where the maggot will be found, there will also be found a vascular pencil running up from a medullary ray in the bulb, and bearing on its top a bud of the same description as that produced by a ray running out from a root. The insertion of the ovipositor brings a medullary ray into action, producing a tuberculated bud, and it is only the bud which the larva feeds upon. The growth of a bud is an intelligible cause of the growth of a gall, but we can infer nothing from the injection of a fluid.

All insect galls are in reality leaf-buds, or fruit-buds. They are not mere amorphous excrescences. The vascular lines which would form leaves can easily be followed up the structure of the oak-leaf galls. And in cases where the egg has been deposited in the tissue of a young branch the cap of the gall is sometimes surmounted by a leaf two or three inches long. But in the large blue Turkish galls many lacunæ occur where the fleshified leaves have not filled up the spaces between them. The morphology of the hollow woody shell, and its inclosures of starch, &c., found in the interior of these galls I hope to work out by and by. It is a curious fact that various microscopic fungi are matured in the interior of imperforate galls.

A. STEPHEN WILSON

North Kinmundy, Aberdeen

[1] In selecting the particular station on the plains to be used in each case, I have endeavoured as far as possible to fulfil two requisites: (1) proximity to the hill-station, (2) low elevation above sea-level.

Cyclones

Mr. Barham, in Nature (vol. xviii. p. 249), concludes that "a cyclone is occasioned by the meeting and passing each other of a northerly and a southerly current, so that they pass each other on the left hand respectively." Supposing this to be true for the northern hemisphere, we must for the southern hemisphere substitute *right* hand for *left*.

There is nothing in this contrary to dynamical principles, but the facts of the geographical distribution of cyclones appear to show that the eddies or swirls in which they originate are formed, not by north and south currents *passing* each other, but by the same *meeting* each other, that is to say, in the zone where the north and south trade-winds meet, when this zone is at some distance from the equator. Cyclones are not formed on or near the equator, because there the earth has no rotation relatively to an axis drawn vertically to its surface.

Mr. Blanford has written in Nature (vol. xviii. p. 328), showing that Mr. Barham has not accounted for the motive power of the cyclone, and explaining it by the liberation of latent heat from the condensation of vapour in an ascending current at the centre of the cyclone. This explanation was first given by Espy in his "Philosophy of Storms," and is certainly true. But the two questions are quite distinct, viz., what sets the cyclone going? and, how is it supplied with motive power?

Three conditions are needful for the formation of a cyclone—first, an eddy produced where currents of air meet; second, sufficient "steam power of the atmosphere," as Espy calls it, to produce a strong in-draft to the centre of the eddy; third, a position sufficiently far from the equator for the currents of air towards the centre to be sensibly deflected by the earth's rotation.

But how is the in-draft first set up? I reply, by the centrifugal force of the eddy causing a barometric depression at its centre, whence follow cold, the condensation of vapour, and the liberation of heat which had been latent. The liberated heat expands the air in the upper strata, thus supplying the motive power of the cyclone.

Joseph John Murphy

Old Forge, Dunmurry, Co. Antrim, April 20

Showers of Rain and Gusts of Wind

It is a matter of common observation that showers of rain are usually accompanied by more or less violent gusts of wind, but as far as I know no explanation of the fact has yet been offered.

The cause I am about to suggest must be productive of some result, but whether it is sufficient to account for the whole phenomenon I cannot say without quantitative observations, though I guess it is.

It is quite certain that the actual velocity of even large drops of rain is very small compared with that which they would acquire by falling through the same height *in vacuo*, and, practically, a drop may be considered to fall with uniform velocity during the whole time of its descent.

Now, after a drop has ceased to accelerate, it leaves an amount of water in air equal to the weight of the drop multiplied by the distance through which it falls, and most of this will appear as a current of air accompanying and following the drop.

In fact, when the drops which compose a shower are falling without accelerating, the air through which the shower falls is acted on by a downward force equal to the weight of the shower, and the downward current of air thus caused must spread laterally as it approaches the ground.

Thus, if a shower were to fall on a calm day, there ought to be a wind on the ground blowing in all directions from the shower as a centre. The rough experiment of throwing a shovelful of sand into the air and watching the dust as it reaches the ground serves very well to show the kind of thing which must happen. But when there is a wind blowing at the time the shower falls, which is generally the case, another, and perhaps more potent, cause than the mere lateral spreading of the downward current comes into operation.

The wind at the surface of the ground is moving more slowly than that at a higher level, because of the retarding effect of friction, and the effect of the shower will be to import air with a high lateral velocity from the upper regions to the lower, where the velocity is small.

With regard to the magnitude of the force which the shower exerts on the air, if we take the rainfall as 2 centimetres per hour, the velocity of the falling drops as 7 metres per second, and the height of the cloud as 700 metres, not improbable numbers for a thunder-shower, the pressure per square metre of shower is 560 grammes; but the downward velocity which this force would generate in the air would depend on the total area of the shower, and would vary from place to place in the shower itself.

Phosphorescence

The study of phosphorescence has lately received a considerable impetus, mainly from its having been made use of in a commercial form for clock faces, door plates, &c., but as Prof. Morton lately remarked, the present producers must have discovered some method of greatly increasing the luminosity of the sulphide used. After great difficulty I succeeded in getting a small quantity from the French makers, the same that I know Mr. Crookes had in obtaining it from the same source. Its luminosity is undoubtedly infinitely superior to that of any of the old methods of production, and gives hopes that further advances may be made. My reason for troubling you with this letter is to put on record a curious fact that has come under my notice in making some experiments detailed in the *Photo News* for May 2, with a view to making luminous photographic images in various ways—that is, that not only light, but heat produces the phosphorescent light. If we take a sheet of card and dust it over with the powder, after coating it with a sticky varnish and allowing to dry, we have a surface that when exposed to daylight for a few seconds will remain luminous for a certain time afterwards. If we place a transparent positive in front we have an evanescent photographic image presented to us on removing to a dark room, but if after simply exposing the sheet to daylight we place the tips of the fingers against the back of the card, spots of two or three times the luminosity will appear at these places showing that the heat from the hand has a great increasing action. The same occurs if the paper has not been exposed to light, the mere warmth of the hand being sufficient to render the sulphide luminous. Here we have light produced by warmth on a small scale. That phosphorescence is yet in its infancy I am convinced, and also that it will yet have a greatly extended future.

Manor House, South Norwood, S.E.

A Large Egg

One of my Houdan fowls has laid an egg weighing 7 oz.; her ordinary eggs weigh 2½ oz. I ordered my man to blow the egg in order to preserve the shell, when I was surprised to find that, besides a small yolk and much white of egg, it also contained a *perfect ordinary-sized egg*. This is now lying loose within the large shell, which latter measures 8¼ inches and 9¼ inches in its two principal circumferences.

Barham, Ipswich, May 6

THE IRON AND STEEL INSTITUTE

The annual spring muster of this young and vigorous society, now in the tenth year of its age, and numbering close upon a thousand members, was held, according to custom, in the house of the Institution of Civil Engineers in Great George Street, last week. This gathering has been awaited with considerable interest for some time past, as communications of more than usual importance were expected upon the problem of dephosphorising ordinary brands of cast iron, such as are smelted from the stratified ores of Cleveland, Lincolnshire, and Northamptonshire, sufficiently to be able to produce from them steel of fair merchantable quality; and the attendance fully justified the expectations, the large meeting room being, as a rule, filled to overflowing each day within a very few minutes after the opening of the proceedings. With the exception of a morning devoted to complimentary and formal business, including the address of the new president, Mr. Edward Williams, who succeeds Dr. Siemens, and, in a few pages, presented a bold and rapid sketch of the progress of the malleable iron and steel industries since 1855, the year of Bessemer's great invention, and the presentation of the medal to Mr. Peter

Cooper, of New York, the father of the American iron trade, and the founder of the Cooper Institute, probably the largest free technical school in the world, the three days of the meeting were given up to the reading and discussion of papers in the thorough and workmanlike manner that has distinguished the Institute from its earliest meeting to the present time. Of prominent interest among these communications was undoubtedly that by Messrs. Thomas and Gilchrist on the Elimination of Phosphorus in the Bessemer converter, describing a series of experiments in continuation of others previously brought before the Institute, made at Blaeravon and Dowlais in South Wales and at Messrs. Bolckow and Vaughan's steel-works in Cleveland. The essential novelty in these experiments is the use of lime and oxide of iron as a flux in the Bessemer converter, lime being also used as a refracting lining in place of the ordinary siliceous sand or ganister. By this comparatively simple change it is found that the highly phosphuretted iron of Cleveland, containing 1 per cent. and upwards of phosphorus, may be so completely purged from that objectionable metalloid as to yield a steel, or rather, to use the proposed international nomenclature, an "ingot metal," which in this particular compares favourably with that blown from hematite pig-iron, the amount of phosphorus ranging from ·03 to 0·15 per cent. in various samples.

The presence of a large excess of earthy base, *i.e.*, lime, in the slags, appears to be the essential condition of success, and the formation of such a fluid basic slag at an early stage of the operation is of equal importance, as it enables the oxidation of both carbon and phosphorus to go on simultaneously. The composition of these slags is utterly unlike those obtained in the Bessemer process, as ordinarily worked, which are essentially similar to manganese augite; while those of the new process contain from 33 to 37 per cent. of lime, and about as much silica; though not exactly representing any natural mineral, are nearer in constitution to the olivine group of silicates. That the phosphorus is removed as phosphate of calcium, probably diffused through a mass of smolten silicates of calcium iron and manganese, there can be but little doubt, but the point, apart from its practical bearing, is of considerable scientific interest, and it seems not unlikely that microscopic investigation might throw some light upon it, unless, indeed, the slags should prove so opaque as to resist this particular method of inquiry. At any rate, one cannot but be struck with the analogous occurrence of apatite in basalts and other igneous rocks containing a low proportion of silica.

As regards the practical value of the process it would be premature to speak; many of the points raised in the discussion by way of objection, such as the increased volume of slag produced, a serious nuisance in the comparatively confined space of a Bessemer casting pit, the possibly small duration of the converter linings, &c., being obviously only matters of detail. That a very considerable success has been achieved in these experiments there can be no doubt, and that the iron smelters of Cleveland as well as those of Luxemburg and Lorraine will be fully alive to the advantages which the new process promises them is equally certain. At the same time the hematite iron trade, though not so completely master of the field as formerly, will no doubt be fully able to hold its own, and there will probably be found to be ample room for both east and west coast as steel producers. Some among us may hope as a consequence to hear less o the so-called phosphorus steels produced by dosing phos phorised iron with manganese, now that the more rational method of taking the phosphorus out of the iron may be used, in preference to disguising it.

The paper by Mr. Snelus covers nearly the same ground as that of Messrs. Thomas and Gilchrist, as it describes a number of experiments made in Bessemer converters with a lime lining first at Dowlais and subsequently Workington in Cumberland some years since with substantially the same results. That these experiments were not further carried out is sufficiently explained by the fact of the author being at the head of an establishment producing one of the purest qualities of cast-iron in the country, and therefore his interests were not in the direction of making lower class metal available; and any one who knows how the West Cumberland Works have progressed under Mr. Snelus' management will find sufficient excuse for his name not being more prominently identified with the new process. The fact of a West Coast man having been the first to demonstrate the feasibility of steel-making from Cleveland iron is a source of gratification to the local papers, and to those who have neither Cumberland nor Cleveland proclivities, it will be gratifying to know that two of the three authors of the paper in question, namely, Messrs. Gilchrist and Snelus, are graduates of the Royal School of Mines. As a contribution to the working out of the practical details of the process, Mr. Riley's paper deserves notice, although no very considerable principle is involved. The use of lime as a lining for Bessemer and other steel-melting furnaces is attended with some difficulty, as the consolidation of dry quicklime by ramming and subsequent heating is in many ways an unsatisfactory method, and its conversion to a plastic mass by means of water is not possible, owing to the chemical changes set up by hydration. These inconveniences Mr. Riley proposes to remedy by making the lime plastic with petroleum or other hydrocarbon oils, giving a mass which can be moulded by pressure and consolidated by burning in the same way as ordinary fire-bricks, the small quantity of oil being driven off at the temperature of firing. The material used is the magnesium limestone of Yorkshire, which gives bricks sufficiently hard to resist carriage and a certain amount of hard usage. Of the other papers read, that by Mr. Pattinson, of Newcastle-on-Tyne, describing a new method of determining manganese in iron and iron ores, is of considerable value as giving an exact method of indirect analysis which can be carried out in a short time as an alternative to the rather tedious direct methods of determination at present in use.

The remaining communications, more particularly those on the various uses of steel, as for example, in ship building by Mr. Barnaby, in bridge building by Mr. Maynard, and in general engineering work by Mr. Adamson, though of interest, are more so from the discussions produced than from any positive information contained. The close of the meeting was marked by the announcement of Dr. Siemens' munificent offer of 10,000*l.* towards the building fund of a new house for the Institute and the other societies representing applied science, to be erected in Westminster, a project which has been spoken of for some time, but which will no doubt with such a favourable beginning soon become a reality. It is to be hoped that in erecting a new scientific palace, whether on the Thames Embankment or elsewhere, the example of Burlington House will not be followed, where a large and costly pile of buildings has been erected without a single good-sized meeting-room in any one of the houses.

THE METEOROLOGICAL CONGRESS AT ROME

THE second International Congress of Meteorologists has just been held at Rome, on the invitation of the Italian Government. At the time of the first Congress at Vienna in 1873, it had been wished that a second should take place in three years' time, but for various reasons the meeting was postponed until Easter, 1879. Delegates were present from all the countries of Europe except Turkey, and Gen. Myer of the United States crossed the Atlantic, but, unfortunately, to arrive too late. The actual foreign delegates present were:—(Aus-

tria) Dr. Hann, Dr. Lorenz, Dr. Paugger, Dr. Müller, and Lieut. Weyprecht; (Hungary) Dr. Schenzl; (Bavaria) Dr. v. Bezold; (Belgium) Prof. Houzeau; (Denmark) Capt. Hoffmeyer; (England) Prof. Smith and Mr. Scott; (France) M. Hervé Mangon, Prof. Mascart, Lieut. Brault; (Germany) Dr. Neumayer, Dr. Bruhns, Dr. Auwers; (Greece) Prof. Kokides; (Holland) Dr. Snellen; (Norway) Prof. Mohn; (Portugal) Capt. de Brito Capello; (Russia) Prof. Wild; (Spain) M. Aguilar, Capt. Pujazon; (Sweden) Prof. Rubenson; (Switzerland) Prof. Plantamour; Italy sent Prof. Blaserna, Prof. Palmieri, Padre Denza, Prof. Tacchini, M. Salvatori, Prof. Pittei, and Prof. Cantoni. Of foreign guests there were present Dr. Hellmann, Prof. Mendeleef, Prof. Weihrauch, and Prof. Zenger.

Prof. Buys Ballot, the president of the Committee which had made the preparations for the Congress, was unavoidably absent, owing to domestic affliction, and his place was taken by Prof. Cantoni, who was elected president of the Congress. MM. Plantamour[1] and Wild were elected vice-presidents, with Capt. Hoffmeyer and Mr. Scott as secretaries.

The proceedings were opened on April 14 by M. Depretis, the Premier, in the absence of the Minister of Agriculture and Commerce, M. Majorana Calatabiano. A reply to his speech had been prepared by Prof. Buys Ballot, and was read by M. Mascart. Mr. Scott then read the Report of the Permanent Committee of the Vienna Congress, containing a list of the special treatises prepared for submission to the Congress at Rome. The existence of these treatises, several of which are of considerable value, forms the most important feature of the proceedings of the meeting of 1879.

For the consideration of the several questions of the programme, five committees were appointed: 1. Organisation; 2. Publications; 3. Instruments and Observations; 4. Telegraphy, Maritime Meteorology and Agricultural Meteorology; 5. Distant Stations and Mountain Observations. The Committees met frequently, and the Congress held five general meetings, concluding its business in eight days of very hard work.

The following will give a general idea of the resolutions adopted:—

The idea of an international institute met with very little favour, but instead thereof, an international meteorological committee consisting of nine members was elected. This body possesses no executive powers, but is charged with the duty of endeavouring to forward the prosecution of definite inquiries into various meteorological problems by friendly co-operation between the several institutes and individuals who may be disposed to undertake such inquiries, as, *e.g.*, the construction of isobaric charts for the globe. The committee has also to see to the carrying out of the resolutions of the Congress, and to report on the degree to which those of the Vienna congress have been carried out. The members of the committee are chosen from different countries, and their names are as follows:—

Buys-Ballot (Holland), Cantoni (Italy), Capello (Portugal), Hann (Austria), Mascart (France), Mohn (Norway), Neumayer (Germany), Scott (England), Secretary, Wild (Russia), President. All communications are to be addressed to Mr. Scott. As regards the form of publications, the schedules proposed in 1874 by the permanent committee of the Vienna congress were adopted, and, ir fact, are already very generally in use. The Congress took no measures to enforce uniformity of hours of observation, the problem presenting too many difficulties. Each country was invited to prepare for its own principal stations corrections for diurnal range for the more important elements. The preparation of a catalogue of existing meteorological literature, including papers in periodicals, was recommended, such catalogues having already appeared at Brussels and in London (for the library of the Meteorological Society).

With reference to the subjects embraced under "instruments and observations," the most important resolutions were the following:—

The different institutes were recommended to effect a comparison of their respective standard instruments; the method of determining the fixed points of thermometers proposed by M. Pernet in his report on the subject was provisionally approved; the Congress did not venture to prescribe a single mode of exposure for thermometers suitable to all climates; the subject of earth-temperature was strongly recommended for study. The Congress received a communication from a M. de Rossi, on what he calls "endogenous meteorology," *i.e.*, the influence of atmospherical changes on earthquakes, and recommended him to prosecute his studies further.

The regulation of the Vienna congress in favour of very large rain gauges was rescinded, as well as that prescribing a height of 4½ feet above the ground for the instrument.

The international telegraphic code proposed in 1874 was recommended for general adoption. It was not found practicable to introduce into it a notice of "cirrus" cloud observations, but this latter subject was strongly recommended for study.

The subject of ocean meteorology was left to the special offices which are occupied therewith. With reference to the simultaneous observations made for the U.S. Signal Office, the Congress hoped they will be continued. As to the construction of daily synoptic weather charts for the Atlantic and Europe, a joint proposal by Dr. Neumayer and Capt. Hoffmeyer to continue and enlarge the scope of the charts published by the latter gentleman was approved. In regard of agricultural meteorology, it was decided to recommend that a private conference of persons interested in and possessing special knowledge of the subject should be held in the course of the next twelve months.

With reference to the establishment of stations in distant islands, as, *e.g.*, in the Pacific Ocean, it was decided that none such could be organised by international co-operation, but that individual governments should be requested to found stations in such localities, and that all maritime nations should be requested to instruct the officers of any exploring expeditions they may respectively send out to visit any such outlying stations as occasion may offer.

As regards Continental stations in low latitudes, the Congress resolved to request the Brazilian Government to establish meteorological stations, and to request the Royal Society of London to endeavour to secure the continuation of the publication of Mr. J. Allan Broun's work at Trevandrum. Several resolutions were passed relating to the importance of observations taken in balloons and on mountain tops. The subject of the changes in the size of glaciers, as indicating changes of climate, was recommended to the notice of the Alpine Clubs.

The final resolution of the Congress had reference to the proposal of Count Wilczek and Lieut. Weyprecht to maintain for a year a series of observing stations round the North Pole. It was resolved that, if possible, an official conference of representatives from governments disposed to co-operate in the undertaking should be held at Hamburg in October next; M. Weyprecht explaining that he could not accept a later date for the conference, as his own departure for Nova Zembla, his chosen post, would take place before next spring, and as the funds for his expedition were already contributed. The meetings terminated on April 22.

The Congress was entertained with the most splendid hospitality. His Majesty the King received the delegates at a banquet on April 21, on which occasion they were

[1] M. Plantamour's name was inadvertently omitted from our note of NATURE, vol. xix. p. 590.

personally presented to the King and Queen, who conversed most graciously with each of them. On the 22nd the Minister of Agriculture entertained the Congress at a State dinner. On the 20th the Syndic of Rome had given a reception in the Capitoline Museum, which was illuminated for the occasion. For their own part the foreign delegates invited their Italian hosts to a dinner at the Hotel de Russie on the 19th.

The proceedings were closed by a very graceful and munificent act of hospitality. The entire Congress, with the ladies who had accompanied some of the members, received free tickets for Naples and became the guests of the Italian Government for two days and a half. An expedition to Vesuvius, which was arranged for them, proved a complete success. The courtesy and forethought of the Italian officials extended to every detail which could contribute to the comfort of their visitors. The day was one of unclouded enjoyment; the weather was a perfect specimen of an Italian spring, and Vesuvius was tranquil enough to allow the more adventurous members of the party to explore every part of the crater, only deigning to eject a few stones as Parthian arrows at the descending meteorologists.

The Congress at Rome will remain in the memory of all who took part in it as one of the pleasantest and most successful opportunities of international scientific intercourse which has ever been organised.

OUR ASTRONOMICAL COLUMN

TEMPEL'S COMET (1867 II).—The following ephemeris of this comet is deduced from M. Gautier's elements, but with the perihelion passage corrected to May 6·9537 G.M.T. to accord with the approximate position observed by Dr. Tempel on April 24:—

At Greenwich Midnight

1879.	Right Ascension. h. m. s.	Declination. ° ′	Log. distance from Earth.	Log. distance from Sun.
May 15	16 50 3	−16 17·6	9·8959	0·2487
17	— 49 15	16 36·6		
19	— 48 20	16 55·9	9·8911	0·2492
21	— 47 20	17 15·6		
23	— 46 16	17 35·8	9·8880	0·2498
25	— 45 8	17 56·3		
27	— 43 58	18 17·1	9·8866	0·2506
29	— 42 45	18 38·1		
31	— 41 31	18 59·3	9·8871	0·2515
June 2	— 40 16	19 20·6		
4	— 39 2	19 42·0	9·8895	0·2527
6	— 37 49	20 3·4		
8	— 36 38	20 24·8	9·8937	0·2539
10	— 35 29	20 46·1		
12	16 34 23	−21 7·2	9·8996	0·2554

The intensity of light is at a maximum about May 26, but is not then very materially greater than on April 24, when the comet was described by Dr. Tempel as a faint object. In 1867 it was observed at Athens until the theoretical intensity of light had diminished to 0·21, so that with the larger telescopes in the southern hemisphere observations may be possible in August. The position for August 13·5 is in R.A. 16h. 58·8m., Decl. − 29° 11′. When brightest in 1867, the nucleus was star-like and of 9·7 m., the value of I. at the time being 1·23.

During the ensuing revolution considerable perturbation may again result from the action of the planet Jupiter, though not to so great an extent as in the revolution 1867-73. Using the above time for perihelion passage in the present year and taking the mean daily motion, 593″·184, it appears that the least distance of the comet from the planet will be about 0·58 of the earth's mean distance from the sun, in the middle of October 1881, and that from the beginning of July, 1881, to the middle of January, 1882, the comet will always be within 0·65; this will again necessitate a rigorous calculation of the perturbations to insure a near prediction of the comet's track in the heavens in 1885.

It was at one time suggested that the object detected by M. Goldschmidt on May 16, 1855, while searching for De Vico's comet of short period, might have been the comet of which we are writing; but the late Dr. von Asten undertook the calculation of the perturbations backward for two revolutions from 1867, and found that the comet being in perihelion on February 1, 1856, with elements not very different from those of 1867, could not have been identical with Goldschmidt's nebulosity. So far, therefore, as is known at present, there is no recorded observation of Tempel's comet previous to April 3, 1867, notwithstanding it may have performed many earlier revolutions in the restricted orbit it now describes; but the case is similar with other comets of short period.

BRORSEN'S COMET.—Dr. Krueger has kindly sent us two meridian observations, made at Helsingfors, of the star over which Major Tupman witnessed a nearly central transit of this comet on May 3 (NATURE, vol. xx. p. 27). The star was rated 8·7 mag., and its mean position for 1875·0 was R.A. 6h. 9m. 14·84s., Decl. + 61° 28′ 8″·5. Whence the apparent position of the comet by Major Tupman's observation was on May 3, at 10h. 11m. 14s. G.M.T. in R.A., 6h. 9m. 39·15s., Decl. + 61° 28′ 30″·9, showing corrections to the ephemeris, published in this column, of + 13s. in R.A., and + 2′ in declination.

ANNUAIRE POUR L'AN 1879, PUBLIÉ PAR LE BUREAU DES LONGITUDES.—It has not been from want of appreciation of the astronomical contents of this small volume, so ably edited by M. Lœwy, that earlier allusion to it has not been found in this column. It provides information of a kind which is not to be met with in so collective a form elsewhere, and must be a valuable adjunct to the astronomical amateur, who needs reference to a really reliable authority on such details as the maxima and minima of variable stars and the general elements of the solar system, including periodical comets. M. Lœwy presents in one list the positions and limiting magnitudes of the variable stars of which the periods are known, and in a second list similar particulars of a large number of stars known to be variable, but of which the periods have not yet been determined; these lists are followed by an ephemeris of maxima and minima, arranged in order of date, with the minima of the more rapid variables, Algol, λ Tauri, S Cancri, δ Libræ, and U Coronæ. There is also a carefully-prepared list of the elements of the minor planets to No. 191 inclusive, such a catalogue, in fact, as has often been inquired for by those who do not see the *Berliner Astronomisches Jahrbuch*. The general contents of the *Annuaire* are as full and varied as usual, but for the reasons named it has now an especial value for amateurs of astronomy, and its almost nominal price places it within reach of all. M. Janssen makes an important addition in his "Notice sur les Progrès récent de la Physique solaire," which is accompanied by a photograph of a portion of the sun's disc, taken at the observatory at Meudon, June 1, 1878, illustrating the rapid transformations occurring in the photospheric network and granulations within less than an hour.

AN INTER-OCEANIC CANAL

TO-DAY the long-talked-of International Congress on the subject of a canal across the Central American Isthmus meets in Paris under the presidency of M. De Lesseps. This question is a very old one, but the movement which has led up to the present Congress commenced only in 1875, at the instigation of Lieut. Lucien N. B. Wyse, of the French Navy. At the International Congress of Geography of that year the subject of the

piercing of the American isthmus was seriously discussed. Under the presidency of M. De Lesseps an international jury was appointed to decide upon the best track and to give its opinion on the financial and economical possibility of the execution of the scheme. It was resolved to postpone the meeting of the grand jury until after the exploration of the Paya-Caquirri line. In less than a year a society of exploration was constituted, the capital subscribed, the concession of a canal obtained from the Government of Columbia, and towards the end of 1876 an expedition set out from France for the Isthmus of Darien under the command of Lieut. Wyse. From that time till a few months ago, Lieut. Wyse, with the aid of Lieut. Reclus, M. Sosa, and a staff of engineers, surveyors, &c., has been carrying on his explorations in various parts of the isthmus, so that now a vast quantity of data has been collected, and will be brought before the Congress which meets to-day. Whatever decision the Congress may come to on the immediate subject under discussion, the value of these, as well as previous explorations in connection with an inter-oceanic canal, are very great so far as our knowledge of Central America is concerned. They have added much to the scanty information we had on the physical geography, hydrography, fauna and flora of the region explored.

Not to go farther back, the first serious work of the isthmus in recent years, with a view to the construction of a canal, seems to have been undertaken by the French engineer, Napoleon Garella, who in 1843 explored the isthmus of Panama, and proposed a canal with locks and a tunnel from Simon Bay, in the Atlantic, to the Bay of Vaca de Monte, in the Pacific. But it has been the United States which, until the French Expedition, has been most earnest in the task of endeavouring to find a practicable route for such a canal, as, on the face of it, to them, in spite of their trans-continental railway, it would be of immense commercial advantage. It would reduce by more than half the sailing distance between their east and west coasts. Therefore since 1850 numerous expeditions have been sent out by the U.S. Government to

Central American Isthmus. The Longitudes are reckoned from Paris.

explore the isthmus with this view. In this way have surveying expeditions visited Nicaragua (1850), the passages between the Atrato and the Pacific, by the San Juan, the Baudo, and Cupica Bay (1850-51), the isthmus of San Blas, the narrowest part of Central America (1854), Humboldt Bay, and the Atrato, by the Truando Valley (1858-59), the Paya and the Atrato (1865). As none of these had satisfactory results, the United States Government resolved to send out a large and thoroughly equipped expedition, once for all to settle the question. For three years the expedition carried on its work, with excellent results so far as science is concerned. Tehuantepec was explored by Commodore Schufeldt, Nicaragua by Commodores Hatfield and Lull, Panama by Lull, Isthmus of San Blas, that of Darien, between the Sabana and the Bay of Caledonia, and between the Tuyra and the Atrato, by Commander Selfridge, the Atrato-Napipi by Selfridge and Collins. This expedition did not contemplate any other kind of canal than one with locks, and moreover did not examine the whole of the passage of the Paya, an affluent of the Tuyra, examined in part by M. de Lacharme in 1865. This was the state of matters when Lieut. Wyse's expedition entered upon the field, one of his chief objects being to examine thoroughly the passage from the Rio Paya to the Rio Caquirri, an affluent of the Atrato, and to discover if it were not possible to construct a canal on a level throughout, dispensing with locks, and constructing instead one or more tunnels. Lieut. Wyse and his colleague, Lieut. Reclus, point out the many advantages a level canal has over one with sluices, and by one or more of the routes they think such a canal could be constructed, and make light of the construction of a tunnel. The passages explored by Lieut. Wyse's expedition were those between the end of the Gulf of Uraba and the Gulf of San Miguel; from Acanti at the mouth of Uraba Gulf to San Miguel Gulf; from San Blas Bay to Chepillo Roads and the head of the Gulf of Panama; from Simon Bay to Panama Roads; and from Greytown to Brito Creek.

The following is a summary of the various schemes that are to be brought under the consideration of the

Congress, the numbers corresponding with those on the sketch-map which we give. The first six lie within the United States of Columbia, and the last in Nicaragua and Central America.

1. This line is in the state of Cauca, and extends from the head of the Gulf of Uraba on the Atlantic side to the bay of Chiri-Chiri. The total length between the two oceans is 290 kilometres, of which 50 are canal proper, and the rivers utilised would be the Atrato, Napipi, and Doguado. The volume of excavation would amount to 29,000,000 cubic metres, and of embankment 3,000,000. This canal would require twenty-two locks, and a tunnel six kilometres long. There are a good many objections to a canal along this line, which the American Commission placed only in the second class; besides the locks and tunnel, it would be difficult to make a good port at Chiri-Chiri. It would take nine years to make.

2. The second line is in the States of Cauca and Panama, and runs from the head of the Gulf of Uraba to Darien Harbour and the Gulf of San Miguel. It is 235 kilometres long, 128 being canal, the rivers utilised being the Atrato, Caquirri, Puquia, and Cué, or rather the Tibule, Paya, and Tuyra. It would require 22 locks and 1 kilometre of tunnel, or without a tunnel, extremely deep excavation. The material excavated would amount to 60,000,000 or 65,000,000 cubic metres, and the embankments, &c., to 6,000,000. The tertiary formation along this route presents comparatively soft rocks, and there are fine ports at the two extremities. It would take twelve years to make.

3. The third scheme is in the same State as the previous, but the line goes from Acanti at the entrance to the Gulf of Uraba, to the same Pacific terminus as No. 2, utilising the Tolo, Tiati, Tupisa, Chucunaqua, and the Tuyra. Its length would be 125 miles, of which only 74 would be canal. It would require 70,000,000 cubic metres of excavation; there would be no locks, but a tunnelling of 17 kilometres, which is a great objection, combined with the elevation of the point of departure and the difficulty of sinking shafts. It would take twelve years to make.

4. This route lies in the Chepo district of Panama State, going from the Bay of San Blas to opposite Chepillo Island, at the head of Panama Gulf. The length is fifty-three kilometres, forty-two being canal, the rivers utilised being the Nercalegua, Mamoni, and Bayano. The material excavated would amount to only 34,000,000 cubic metres, there would be no lock, but 16 kilometres of tunnel. This last point is, of course, an objection. The length of time would be ten years.

Nos. 5 and 6 are both in the Colon and Panama departments of Panama State, and, as will be seen, are to a considerable extent coincident. The former is 72 kilometres long, all canal, the River Chagres being made use of. The amount of excavation would be 57,000,000 cubic metres, and of embankment 5,000,000; there would be 25 sluices and no tunnel, and it would take six years to make. No. 6, again, would have no sluices, but tunnelling 6 kilometres long, with 47,000,000 cubic metres of excavation. It would be 75 kilometres long, and the rivers Chagres and Rio Grande would be utilised. Each would take about six years to make, and would cost about the same sum. They are near the Panama Railway, pass through a well-peopled region, and there is no difficulty as to ports. Lieut. Wyse's commission, however, advocate warmly No. 6 scheme, as being preferable to any other. The time wasted in passing locks, the difficulty and expense of maintaining them, and other considerations, induce them to advise that all idea of a canal with locks should be abandoned; and of all possible level canals with tunnels, that numbered 6 seems to this commission altogether the one presenting the most favourable conditions.

The scheme numbered 7 is in the state of Nicaragua and Costa Rica, and passes from Greytown on the Atlantic side, to the Bay of Brito on the Pacific. This line would be 292 kilometres long, 195 being canal, the San Juan, Lake Nicaragua, and the Rio Grande being utilised along the route. The excavations would amount to 48,000,000 cubic metres, and embankments, &c., to 5,500,000, and there would be twenty-one locks and no tunnel. There are too many objections to this line to attract the favourable consideration of the Congress. There are, *e.g.*, the complete absence of ports, difficulty of constructing and maintaining them, insalubrity of nearly the whole of the Atlantic slope, length of the canal, and the political instability of the countries concerned. It would take ten years to make.

As to the cost of the various schemes, we may say that it varies from 475,000,000 to 650,000,000 francs, with a yearly sum for maintenance of from 4,000,000 to 15,000,000.

Some statistics as to the dimensions proposed to be adopted for the basin of the canal may be of interest. The breadth of the canal will be about 20 metres at the bottom, 26 metres at 3 metres high, and according to the nature of the ground, from 32 metres as a minimum at the surface in deep cuttings to 50 metres, when steep banks require 2 in 1 of fall. The increase in breadth which is proposed at 3 metres above the bottom is intended to give more play to ships of large bulk and to increase the water-section, which would thus never be less than 224 square metres. The depth of the canal would be $8\frac{1}{2}$ metres. The curves proposed, with a minimum radius of 3,000 metres, are less pronounced than those in the Suez Canal. The crossing stations will have a breadth of 40 metres at the bottom on a length of 500 metres. The tunnelling will also have a depth of water of $8\frac{1}{2}$ metres, a breadth of 20 metres at bottom, but only 24 at the surface. The smallest water-section will thus be 187 square metres. Above the mean level, on each side, there will be a straight space of 4 metres, then an arch of 30° in a radius of 63 metres; the summit will be semicircular, with a radius of only 2 metres. To satisfy all contingencies the height of the vault above the level of the water will reach 34 metres, which will allow the largest vessels to pass by a little adjustment of their most prominent masts and yards. The entire subterranean section will be 780 square metres, of which 563 will be above water. It is expected that throughout, very little embanking will be necessary.

Thus, so far as the International Commission is concerned, the information to be laid before the conference is full and exact. So far as we have studied the question there seems no serious physical or engineering difficulty in cutting a canal through the American isthmus between the Atlantic and Pacific; probably the great difficulty will be a monetary one, and even this need not, we suppose, be insuperable, if all other difficulties are removed.

ON THE EVOLUTION OF THE VERTEBRATA[1]

II.

AMPHIBIA (*continued*).—When the history of the development of these forms has been thoroughly made out, the terminology can be put into something like proper form. This will have to be done cautiously, for that which we see as one bone in the larva represents, and may become, two or three bones in the adult, and these may represent bones that start as distinct centres in the higher forms.

In the Urodeles there is one bone (the *pterygo-palatine*) in the larva which plays many parts during metamorphosis, and a different part in different species. At first it is related to no cartilage at all, only arising as a cement to a patch of palatine teeth, but after a time the ethmo-

[1] Abstract of Prof. Parker's Hunterian Lectures, delivered at the College of Surgeons, commencing on February 10. Continued from p. 32.

palatine and pterygoid cartilages appear, and it then subdivides, the pterygoid getting the larger half but no teeth, and the ethmo-palatine the lesser half and all the teeth. The form of these parts varies much in the different genera.

The apparent uniformity of the Batrachia, as to the skull especially, is quite belied by what is found on dissection. The disposition of parts in the skull varies greatly.

A careful study of the morphology of the Batrachia suggests many things as to their genetic origin, and accords very accurately with the known facts of their geographical distribution. On the whole the types are more generalised in the west than in the east, and much more so in the south than in the north.

There is nothing in which the frogs and toads differ more from the salamanders than the extraordinary development of the middle ear; the latter always modify a part of the capsule so as to produce a fenestra ovalis and stapes: but in the former, as a rule, the upper element of the hyoid arch is modified into the chain of the middle ear, the spiracular cartilage into the ring of the ear-parchment, and the skin covering the first cleft into the parchment of the ear drum. In certain kinds of frogs and toads these parts are as much arrested as in the salamanders and newts; in all of them that part of

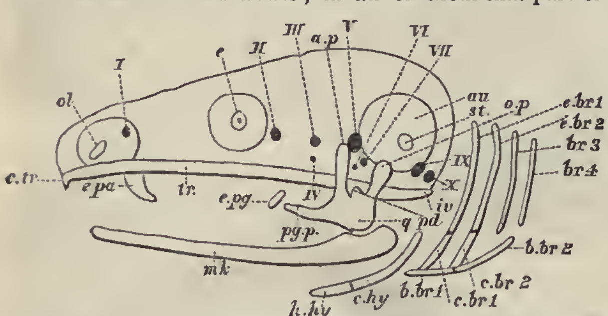

FIG. 2.—Diagram of chondrocranium of young Axolotl. The Roman figures indicate the nerve foramina. *a.p*, ascending process of suspensorium; *au*, auditory capsule; *b.br*, basi-branchial; *br*, branchial arch; *c.br*, cerato-branchial; *c.hy*, cerato-hyal; *c.tr*, coruna trabeculæ; *e*, eye; *e.br*, epi-branchial; *e.hy*, epi-hyal; *e.pa*, ethmo-palatine; *e.pg*, epi-pterygoid; *iv*, investing mass; *mk*, Meckel's cartilage; *ol*, olfactory capsule; *o p*, orbital process; *pd*, pedicle; *q*, quadrate; *st*, stapes; *tr*, trabeculæ.

the hyoid arch which is developed into the middle ear-chain is later in its appearance than that which carries the tongue.

It is evident that the great polymorphism of these types is due to the influence of their surroundings upon them.

The larger kinds are a long while undergoing metamorphosis, and in their adult condition they possess many bones which can only be found again in the long-extinct Amphibians of the Coal Measures. With regard to small and arrested kinds, which, as a rule, belong to the Notogœa, their arrest in metamorphosis can be paralleled with various stages of development in higher kinds. For example, in *Pseudophryne bibronii*, a small Australian bombinator toad, the auditory apparatus is arrested at the same stage in which we find it in our native kind up to midsummer, that is to say, there is no columella; in *Rhinoderma darwinii*, a South American form, the columella is a thick short wedge of cartilage terminating externally in a fibrous thread, precisely like the rudiment we find in our own native kinds in the beginning of July; and in a small African species of frog, *Gomphobutes*, the columella is developed to the condition of that of our native kinds a month or two later, and it is not ossified.

The relative size of the perfect larva to the adult is extremely variable in the Batrachia. In *Bufo chilensis* the recently metamorphosed young is no larger than a common house-fly, the tadpole being about twice the size, and in *Pseudis paradoxa*, a South American form, which is scarcely larger than our native frog, the tadpole attains the size of a herring or a red mullet. In the case of *Pipa monstrosa* from Surinam, the young when ready to leave the dorsal pouches of the mother are scarcely as large as a honey-bee, but as perfect in their metamorphosis as the young of our native frog and toad at the end of a year; the mother toad is twice as large as a large female native toad.

It is evident that those forms in which the tadpole is of such a large size, have a tendency to remain in the larval condition, and are thus a little in advance of the axolotl, most of the individuals of which are arrested as permanent larvæ, a few only undergoing transformation into true gill-less salamanders (*Amblystoma*).

The manner in which the different kinds of Batrachia are modified, both as to their outward form and skeleton, each one to suit its own particular kind of life, is very interesting and instructive. The little tree-frogs have in their skull a large membranous fontanelle, covered merely with skin, as in young infants; their toes are flattened, and thus they are able to climb with ease and safety amongst the foliage, the colours of which they imitate. Other forms, such as *Pelobates fuscus*, living on the ground, have their small brain encased in dense and almost enamelled armour, and besides this protection, the above-mentioned *Pelobates*, or garlic toad, has the power of giving forth an offensive odour from the skin. This last kind is almost devoid of a middle ear, and the columella is extremely small; the little tree-frogs, on the contrary, have very perfect ears. Thus in *Pelobates* we have a skull approaching that of the Labyrinthodonts, while in the tree-frogs the skull resembles very much that of a shark or skate.

Some large kinds, such as *Ceratophrys dorsata*, have, besides the dense bony plates covering the head, similar large scutes over their shoulders.

The frogs and toads that possess a tongue have their eustachian passages wide apart, as in Mammals, but in the tongueless forms, *Pipa* and *Dactylethra*, the two tubes meet at the mid line, as in birds. They have all two separate occipital condyles, as in Mammals.

Taking the Batrachia through and through, they form a wonderfully perfect chain of types; they do not, however, lead us directly to any existing groups of high Vertebrates, but rather look towards Mammalia than in the direction of reptiles and birds.[1]

REPTILES

Snakes.—The snakes have probably arisen from ancestors which possessed limbs, which, however, have become inconvenient to their descendants, and have therefore been supressed. The boas and pythons, as well as the *Typhlopidæ* and *Tortrices*, have, however, rudiments of posterior extremities.

There is a certain embryonic simplicity in the internal skull, but the outer skull is very perfect and marvellously specialised, as is also the spine. There are no exoskeletal elements whatever behind the head, but in the head there are some small cartilages besides the investing bones, which latter form three-fourths of the skull.

The bones of the skull are the most adamantine to be found anywhere in the vertebrate kingdom, while the cartilage, where it survives (as in the *trabeculæ*), is perfectly elastic, and untouched by the ossifying process. Where sutures persist they are perfectly distinct to old age; when ankylosis takes place along any particular line it early obliterates the least trace of the original suture.

A large part of the base of the skull is more simple and embryonic than anything to be seen in the skull of the

[1] Besides the two papers in the *Philosophical Transactions* (1871 and 1876), the lecturer is preparing a large memoir on the structure and development of the skull in a large number of larval and adult forms of Batrachia.

adult lamprey, while other parts are as much specialised as anything that can be found in the skull and face of a man. There are no *dermostoses*, and no instance is known in which a splint bone (*parostosis*) unites with any part of the ossified endocranium, except in the base of the skull, where a rostrum of membranous origin unites with the basisphenoid. The skull is largely formed of splint bones, and the inner parts of the face are also formed of membrane bones, which, however, represent cartilaginous elements in fishes. The outer parts of the face are formed of bones that have no cartilaginous representatives in the lower forms, but exist as splint bones or dermal scutes in the Ganoids, osseous fishes, and Amphibia. So that in a mere study of the development of the snake, without reference to other types, we should find no difference between the premaxillaries and the maxillaries on the one hand, and the palatines and the pterygoids on the other.

The whole apparatus of the palate and upper and lower jaws is a very loosely articulated structure, and each bone is kept as much as possible in the form of a simple bar or splint.

The hinder part of the endocranium and the auditory capsules are intensely ossified, and contrary to what is seen in any other vertebrata, the orbito- and ali-sphenoids are separately developed in the membranous walls of the skull; they are both very small, especially the former. The three bony elements of the auditory capsule remain permanently separate, but the pro-otic unites with the ali-sphenoid, the epi-otic with the supra-occipital, and the opisthotic with the ex-occipital.

The only visceral elements that are developed behind the mandible are the rod of the columella and the minute stylo-hyal which coalesces with the quadrate.

Lizards.—The lizards form a very large group of reptiles, all of which, like the snakes, have a movable pier to the lower jaw, but which have a very remarkable diversity of external and internal characters. Besides the typical lizards, this order includes the Amphisbænæ, the blind-worms, the chamæleons, and the New Zealand *Hatteria* (*Sphenodon*).

For practical zoology, all that can be seen and handled in an animal without dissection is, of course, readiest and best for classification, but to establish a sound foundation, it is necessary to go much deeper. The brain, heart, and other internal organs present very poor distinctive characters in the families under consideration when compared witn the skull, face, spine, and limbs.

In the most serpentiform of lizards there are at least limb girdles even if there are no limbs.

In several kinds, such as the Blind-worms (*Anguis fragilis*) and the Australian *Cyclodonts*, there is a dermal scute inside each horny scale. In the latter and also in the Skinks (*Mocoa*), the underlying parietals and frontals are extensively ankylosed to the overlying bony scutes. In our native sand-lizards the investing bones that lie next the skin, where there are no intervening muscular fibres, become rough and thick, like ordinary dermal scutes; the horny skin over them is thin and has no bony plates under it as in the body. In the larger number of lizards, including the blind-worms, the three normal ventral splint-bones—a pair and an odd one—are seen; in *Hatteria* these are continued along the abdomen segmentally, as in the Plesiosaurs. These bones are suppressed in the chamæleon, which deserves to represent a sub-order by itself, so little has it conformed to the normal type of the lizard.

In the chamæleon the outer bones of the head become crested, scabrous, and fretted with all sorts of markings. In such types as *Monitor*, *Stellio*, and *Iguana*, the cranial roof-bones and the bones of the face are not rough, as in the sand-lizard, nor fretted, as in the chamæleon, but smooth, as in the serpents and birds.

One of the most remarkable things in the skull of some of the types is the retention of rows of bones the counterparts of which must be sought for in the ancient Amphibia of the Coal Measures and in the still more ancient Ganoid fishes of the Old Red Sandstone. In the little nimble lizard, for example, we have two rows of such bones strengthening the eyebrows, and another row over the temporal region, besides a bone flooring the outer nostril, which belongs to the same category.

A sort of anticipation of the hinge of the bird's upper jaw is seen in the sand lizard and in the large stump-tailed lizard of Australia (*Trachydosaurus rugosus*), in which forms a fenestra appears in the orbito-nasal septum. This does not appear in the ostrich tribe, but begins in the Tinamous. Considered evolutionally, this is an exceedingly interesting and instructive fact.

The parietals, which are simply roof-bones, are propped up by a slender rod of bone, the so-called *columella* (*epipterygoid*), which must not be confounded with the bone of the same name in the middle ear. The chamæleons, however, do not possess this bone, and they are also deficient in respect of their ear, having neither the drum and its parchment nor any rudiment of a cochlea.

There is usually only one premaxillary, but in the Skinks and Cyclodonts there are two.

When the birds are spoken of as being genetically related to the lizards, it must be understood that *modern* lizards are not referred to; they are in many respects as

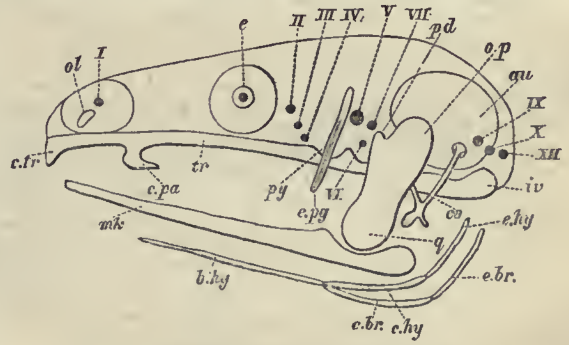

FIG. 3.—Diagram of chondrocranium of Lizard. Letters as before. *b.hy*, basi-hyal; *co*, columella; *py*, pituitary space.

much specialised as the birds themselves, and only form a *side branch*, and not a *leader* of the vertebrate life-tree.

Chelonia (*Turtles and Tortoises*).—The extinction of old, irregular, generalised tortoises has left their descendants in a very neat and orderly state, showing a great uniformity and distinctness from the other reptiles, in the fact that the body is inclosed in a strong bony box formed of the carapace and plastron.

This box is formed of bony plates, covered with horny scales, which, however, do not conform to them. The inner skeleton in the walls and roof of this curious building has become fused with the outer; below there is no inner skeleton, these animals having neither sternum nor sternal ribs, the plastron and the marginal plates of the carapace being formed by ossifications in the dermis. The carapace is principally formed by the bony matter from the spines of the back and of the rib-shafts spreading into the thick overlying web of fibrous tissue.

In some of the Mud Tortoises the edges of the carapace are often soft, and the plastron is very imperfect. In *Chelydra* and the *Matamata* the neck and tail are much longer than usual, and remind the observer of the Plesiosaurs.

The plastron is formed of four bones on each side, the anterior pair being separated by a single median piece, and thus only one of the median ventral bones of a Plesiosaurus or Hatteria is retained.

There are no teeth, the jaws being covered with horn, and forming an efficient shearing apparatus. The facial

bones are few and expanded; the nasals, pre-frontals, and lacrymals are represented by a single bone, and there are no superorbitals. There is no *second* temporal bone, as in lizards, but an additional cheek-bone, the *quadrato-jugal*, unites the jugal to the pier of the lower jaw, a very exceptional thing in lizards (*e.g.*, *Hatteria*.)

The large investing bones have to a great extent aborted the proper internal skull; this is especially the case between the capsules of the ears and the labyrinths of the nose.

In the logger-head and green turtles the cranial compartment has a "shed" or "lean-to" on each side, formed by the parietals, post-orbitals, and squamosals. The pterygoids form the greater part of the bony floor of the skull, between which and the descending wall there is a little bony "prop" corresponding to the *columella* (*epipterygoid*) of the lizard.

The mandible has no *splenial* element, as in bony fishes and frogs. There are two arches developed behind the mandible—the hyoid, or tongue arch, and a second, corresponding to the first gill arch in fishes and Amphibia. The pier of the arch of the lower jaw (*quadrate*) is hollowed into a drum, over which is stretched its "opercular fold," as the parchment, in which there is an annular cartilage. The pier of the tongue-arch is a long slender rod, the *columella*, the proximal part of which answers to the stapes, and the rest to the incus; it stretches between the *fenestra ovalis* and the drum membrane.

This peculiar hollowing out of the quadrate is a promise of the air-cells seen in many of the bones of birds.

The development of the embryo of the Chelonia takes place in essentially the same manner as in birds; yet, in the young of the green turtle, half an inch long, the rudiments of the carapace can be seen.

The parental form of all the modern Chelonia was probably intermediate between the extinct *Rhynchosauria* and the *Plesiosauria*, and the existence in the Cape toad (Dactylethra) of characters that correspond very closely with those of the Chelonia, suggests a relationship between certain ancient forms of the Batrachia and the generalised types from which the Chelonia have sprung.

(*To be continued.*)

GEOGRAPHICAL NOTES

IT would appear as if the War Office authorities expected the special service officers who are on the point of starting for Zululand to find opportunities for doing useful geographical work in that country, as we understand that the Intelligence Department are supplying them with the most recent edition of "Hints to Travellers," published under the authority of the Council of the Royal Geographical Society, and edited by Mr. Francis Galton, F.R.S.

THE news of the death of the Marquis Antinori, the leader of the Italian Expedition to Central Africa, is, we are glad to say, contradicted.

THE Congress of Commercial Geography, to be held at Brussels in September, will be presided over, not by M. Bamps, but by Lieut.-General Liagre, president of the Belgian Geographical Society and perpetual secretary of the Belgian Academy of Sciences. M. du Fief will act as secretary.

NEWS from Leipzig states that the president of the Meteorological Office of that city, Baron A. von Danckelmann has been invited by M. Sibiriakoff to take part in the expedition to the Siberian Arctic Sea, and that he has accepted the invitation, the necessary permission having been readily granted to him by the Saxon Government. The expedition was to sail on May 14.

Les Missions Catholiques publishes an interesting communication from Père Gourdin, a missionary in the Chinese province of Szechuen, in which he gives an account of the little-known tract of country in the south of the province, called Kienchang.

THE last report of Her Majesty's Consul at Newchwang contains much information in regard to Manchuria which is of interest from the standpoint of commercial geography. There are reasons for believing, in his opinion, that in spite of the watershed between the valleys of the Liao and the Sungari, Newchwang will successfully compete with Nicholayesk for the most valuable part of the trade with the latter valley, and those of the two great affluents of the Sungari, the Nonni and the Hurka. A great point in its favour is that the Liao River is remarkably easy of access, while the navigation of the Amur at its entrance is extremely intricate, and is closed by ice for seven months in the year. Colonisation, we are told, is proceeding in the valley of the Yalu-Kiang, the boundary between China and Corea. With regard to the production of opium in regions at a distance from Newchwang, Mr. Consul Adkins says that it is growing in most parts of the province of Fêngtien (South Manchuria), in many parts of the Kirin province, and in a daily increasing area in the southern portion of Eastern Mongolia, notably in the tract of country which lies on the right bank of the Sungari in the angle formed by the reaches of that river above and below its junction with the Nonni, east and south-east of Petuna.

A FURTHER instalment of the *Transactions* of the Asiatic Society of Japan, which has just come to hand, contains some interesting notes of a visit paid last year to the little-known island of Hachijô by Mr. F. V. Dickens and Mr. Ernest Satow, the Japanese Secretary of H.M.'s Legation at Yedo. The island in question, it may be useful to note, is erroneously called Fatsizio on our Admiralty chart; it is the last but one of the chain which extends south of the promontory of Iazu in almost a straight line.

IN a brief account of the work of the China Inland Mission in Burmah we find some notes of interest respecting a visit to the Kah-chen hills near the Chinese frontier. The village visited is situated among the mountains at an elevation of 4,000 feet above the Burmese town of Tsee-kaw. The Kah-chen houses are described as being built of bamboo, and more substantially than those of the Burmese. The roof of each is about 100 or 150 feet in length; at the entrance for some 15 feet the sides are open or merely formed of open bamboo work. The poles which support the roof of this part of the building are ornamented with the heads and horns of buffaloes sacrificed to the *nats* or spirits. On either side of a long passage are small rooms, the first of which is the guest chamber; the kitchen and general sitting-room is at the end of the passage, whence a door, always open, leads into a small raised veranda and which is entirely appropriated to the use of the *nats*, of whom the people are in great dread. The dress of the women is superior to that of their Burmese sisters, than whom they are said to be more modest. All who can afford it, wear a large silver hoop round the neck, and as many strings of red, green, blue, and white beads as they can muster. Their ear ornaments are peculiar; large flaps of ornamented cotton hang from the back of the ear, and tassels or silver tubes are passed through the lobes. All wear large coils of rattan round their bodies, and the younger ones wear bells and cowrie shells. There is, however, one objection to both men and women, viz., their great want of cleanliness.

NOTES

THE University of Edinburgh has sustained a great loss in the unexpected death of its veteran and genial professor of mathematics. Only three weeks ago, in giving the annual address at the graduation ceremonial, he in touching terms

alluded to his long length of service, and the improbability of his again addressing the collected body of graduates. The labours of the winter session had proved too much for his enfeebled health. Immediately after their close he left for the country, where he seemed at first to revive, but a cold which he caught brought on congestion of the lungs, against which he had not strength to rally. He died on the 7th inst. His eminence as a mathematician, and his excellence as a teacher, combined with his admirable personal qualities, will be long remembered by all who have known the Edinburgh University during the last forty years.

THE death is announced of Prof. Grisebach, the well-known botanist and geographer. He was born in 1814 at Hanover, and in 1841 was called as Professor of Botany to Göttingen, where he was still officiating up to his death. He contracted his illness while on a visit with his family to Italy.

M. PASTEUR is about to found, in the department of the Jura, with the support of the French Minister of Agriculture and Commerce, who has for this purpose granted a subvention of 1,000*l*., a special laboratory for the study of all questions connected with the vine and wine. This laboratory, provided with all the means of investigation which bear on researches of this nature, will be located at Arbois, and M. Pasteur will devote six months each year to it. Important results may justly be looked for from this institution.

THE Baly Medal of the Royal College of Physicians of London has been awarded to Mr. Chas. Darwin, F.R.S.

HERR KARL BOCK, who, at the request of the late Marquis of Tweeddale, has spent eight months in exploring the highlands of Sumatra, has, the *Times* states, returned to Padang with a rich collection of natural history specimens. Among other living animals he has secured a specimen of the *Capricornis sumatrensis*, which is peculiar to the island. It is a species of mountain antelope, rarely met with, and only among the most remote and almost inaccessible peaks. Herr Bock was travelling in Lapland in the autumn of 1877, under the 71st parallel of north latitude. The autumn of 1878 was spent by him under the first parallel of south latitude.

A SERIES of "Davis" lectures upon zoological subjects will be given in the lecture-room of the Zoological Gardens, in the Regent's Park, on Thursdays at 5 P.M. The first was given last Thursday by Prof. Flower, on "Birds that do not Fly." The others are as follow:—May 15, "The Pleasures of Zoology," Prof. J. Reay Greene, M.D.; May 22, "Tails," Prof. Mivart, F.R.S.; May 29, "Parrots," P. L. Sclater, F.R.S.; June 5, "Snakes," Prof. Huxley, F.R.S.,; June 12, "Nocturnal Animals," Dr. J. Murie, LL.D., F.L.S.; June 19, "Reptiles and their Distribution," P. L. Sclater, F.R.S. These lectures will be free to Fellows of the Society and their friends, and to other visitors to the Gardens.

MR. ORVILLE A. DERBY contributes to the *Rio News* some interesting information on the plague of rats in Brazil. From time to time in all parts of Brazil the plantations are subject to the depredations of armies of rats that issue from the forests and consume everything edible that comes in their way. During a recent excursion in the province of Paraná Mr. Derby found an almost universal lack of corn throughout the province, due to such invasion of rats, by which almost the entire crop of last year had been destroyed. This invasion, or plague as it is called, is said to occur at intervals of about thirty years, and to be simultaneous with the drying of the *taquara*, or bamboo, which everywhere abounds in the Brazilian forests. The popular explanation is that every cane of bamboo sprouts with a grub, the germ of a rat, within it, and that when the bamboo ripens and dies the germ becomes a fully-developed rat and comes out to prey on the plantations. An educated and observant Englishman, Mr. Herbert H. Mercer, who has resided a number of years in the province and had an opportunity of studying the phenomenon, furnished Mr. Derby the following rational and curious explanation:—The bamboo arrives at maturity, flowers and seeds at intervals of several years, which doubtless vary with the different species. The period for the species most abundant in Paraná is thirty years. The process, instead of being simultaneous, occupies about five years, a few of the canes going to seed the first year, an increased number the second, and so on progressively, till finally the remaining and larger portion of the canes seed at the same time. Each cane bears about a peck of edible seed, resembling rice, which is very fat and nourishing, and is often eaten by the Indians. The quantity produced is enormous, and large areas are often covered to a depth of five or six inches. After seeding the cane dies, breaks off at the root and falls to the ground, the process of decay being hastened by the borings of larva which live upon the bamboo and appear to be particularly abundant at seeding time. These larva have doubtless given rise to the story of the grub developing into a rat. New canes spring up from the seed, but require seven or eight years to become fit for use, and thirty to reach maturity. With this sudden and constantly increasing supply of nourishing food for a period of five years, the rats and mice, both of native and imported species, increase extraordinarily in numbers. The fecundity of these animals is well known, and the result after four or five years of an unusual and constantly increasing supply of excellent food and in the absence of enemies of equal fecundity, can readily be imagined. The last of the crop of seed being mature and fallen to the ground, the first rain causes it to decay in the space of a very few days. The rats, suddenly deprived of food, commence to migrate, invading the plantations and houses and consuming everything that does not happen to be repugnant to the not very fastidious palate of a famishing rodent. If this happens at the time of corn planting, the seed is consumed as fast as it can be put into the ground. Mr. Mercer, who plants annually about fifty acres of corn, replanted six times last year, and finally gave up in despair. The mandioca is dug up; the rice crop, if it happens to be newly sown or in seed, is consumed, as is also everything in the houses in the way of provisions and leather, if not carefully guarded in tin trunks.

THE Congress of the Social Science Association at Manchester has been fixed to take place from October 1 to 8.

Deutsche Acclimatisation is the title of a new German journal devoted to questions connected with the acclimatisation, training, and breeding of birds. It is the organ of the German Society for the Breeding and Acclimatisation of Birds, and will appear at irregular intervals. The editor is Dr. Reichenow.

THE cryptogamous division of the herbarium of the Boston (U.S) Society of Natural History, we learn from the *American Naturalist*, has been enriched by the discovery of a valuable collection of lichens. This was formerly the lichen-herbarium of Dr. Thomas Tayler, an Irish botanist, to whom Sir W. J. and Sir Joseph Hooker gave the whole of their extensive collection of lichens, gathered during many exploring expeditions. Dr. Tayler published descriptions of these plants in the *Journa of Botany*, 1844–66, and many of the specimens are the originals of the descriptions. In 1850 Mr. John A. Lowell purchased the collection from Dr. Tayler's heirs, and it formed a part of the herbarium subsequently presented by him to the Society.

THE following (*ben trovato*, if not the other thing), seems worth reproducing from *Science News*:—It is not long ago that a young man went to one of the wise men at the Smithsonian Institution, and said: "I think I should like to be a naturalist." "Well, *be* one," replied the doctor in charge. "But I don't know how,

and wish you would get me rightly at work at the start." "Very well," said the willing master, "there is plenty to be done right here; let us begin on these fishes." Turning to a can of fishes from Arizona in spirits, he opened the cover, pulled up his sleeve, and brought forth two or three dripping examples. They were well preserved, but the smell—well, the less said about that the better; it was very "ancient" and somewhat "fish-like." "There, see what more you can get out of that can, and I'll show you what to do next." The young man paused in dismay and tugged very gently at his kid glove. Finally, in deprecating tones he asked: "Doctor, is it necessary, in order to become a naturalist, that I plunge my hands in that alcohol?" "Of course—no other way to study objects of natural history properly, except in the field." "Well," was the reply, very decided, albeit somewhat rueful, "I—I think I'll go back to Long Branch." And go back he did.

Dr. Hopkinson gave important evidence before the Electric Lighting Committee last Friday. As a result of his experiments, he found that on an average about 87 per cent. of the mechanical energy bestowed on the machine was converted into heat, but about 50 per cent. of the electricity obtained from the mechanical energy was lost in the heating of the machine and wires. The scientific considerations, he stated, had largely been touched in a satisfactory manner. Mr. Shoolbred, of the firm of Shoolbred and Co., Tottenham Court Road, gave satisfactory evidence of the working of the light in his establishment. He was burning twenty candles, which had replaced 230 gas burners. The cost to him was 37*s.* 3*d.* per night in winter, and 9*s.* 10*d.* in summer.

The American papers state that Mr. Edison is still engaged in his experiments with reference to the electric light, and hopes yet to overcome all difficulties, and to make the light available for public use. He intends to institute a comparative trial on carbon lamps between his own machine and those of Wallace and Gramme; he does not say how many carbon lamps he can light with his machine. He is confident that he can work his system for street and house-lighting with comparatively little loss by exhaustion of the current, by means of a cable, from a central station, the cable composed of as many strands of wire, say one-sixteenth inch diameter, as there are houses in the street to be lighted. The latest papers say that Mr. Edison has perfected his dynamo-electric machine, and with that he maintains he has solved the problem of the economical generation of electricity and the sub-division of the light. A trial of his system is stated to have worked perfectly, producing more lights and less heat with less expenditure of power than any machine hitherto constructed.

The Meudon Aërostatic Service officers are constructing a directing balloon with screw moved by a steam-engine. They have desisted from their original scheme, which was to attach the screw to the equator of the balloon, and have acknowledged reluctantly the necessity of adopting the principles used by M. Henry Giffard, in his celebrated 1852 hippodrome experiment with a steam directing aërostat.

According to official statistics 22,851 wild animals and 127,295 serpents were destroyed in India during 1877; while 16,777 persons died from the bites of serpents, and 2,918 were killed by tigers, leopards, wolves, and other wild animals.

Akhbar, the most influential French paper in Algeria, is devoting many interesting articles to the construction of the Trans-Saharan railway from Laghouat to Timbuktu through Touat. The preliminary surveys have been executed from the Algiers-Oran line to Laghouat.

The last number of the Russian Physical and Chemical Society's *Journal* (vol. xi. fasc. 3) contains the annual reports of the Society, and papers on the temperatures of boiling of saturated hydrocarbons of normal structure, by M. J. Goldstein; on benzoic compounds, by M. P. Goloubeff; on aromatic compounds, by M. E. Wroblevsky; and on the transmission of a galvanic current in water when the platina electrodes are of various sizes, by M. Slouginoff.

In a recently-published inaugural dissertation on the electromotive forces which occur in free water jets (*Ann. der Phys.*, No. 4), Herr Elster arrives at these conclusions:—1. A liquid motion *per se* produces no electromotive force. (This is against Edlund's view). 2. Capillary electric currents are simply produced by friction of the particles of the moved liquid; in the case of non-wetting liquids, by their friction on the particles of the solid wall, and in the case of wetting liquids, by friction on the particles of a layer of the liquid condensed on the surface of the solid, this layer behaving to the less dense as a heterogeneous substance. 3. The capillary electric currents discovered by Quincke are identical with the friction-currents which occur in the rubber of an electric machine, and which were first observed by Zöllner. Numerous experiments in support of these conclusions are described.

News has been received from Japan that two very rich seams of coal have just been discovered in the celebrated Takashima mines. It is estimated that they will produce fully a million tons of coal. It is also reported that active measures are being taken for throwing open to foreign commerce the ports of Tsuruga and Shimonoseki.

The first of two illustrated volumes, on the Manufacture of Sulphuric Acid and Alkalis, by Prof. Lunge, of Zurich, will be published in a few days by Mr. Van Voorst, who has also just ready for publication a supplement to C. Greville Williams's "Handbook of Chemical Manipulation."

The fourth public annual meeting of the Sunday Society will be held in Freemasons' Tavern on Saturday, at 4 P.M. From their just published Report we see that the Society is making marked progress in the objects which they have in view.

The supplement to the *Colonies and India* for May 10 contains a long address given to the Colonial Institute by Prof. Owen on the Extinct Animals of the Colonies of Great Britain.

We have received a most interesting and instructive lecture on Ornithology, by Dr. H. B. Hewetson, of Leeds; its title is "Nature Cared for and Nature Uncared for, the Result upon the Hearts of Men." He tries to show how much pure pleasure can be derived from the observation of living nature, and the study not of the dead animal, but of "the life-sympathies and instincts of the object in life." The lecture deserves a wide circulation. The publishers are West, Newman, and Co., of London.

The additions to the Zoological Society's Gardens during the past week include a Macaque Monkey (*Macacus cynomolgus*) from India, presented by Mr. C. A. Thomson; an Ocelot (*Felis pardalis*) from America, presented by Mr. P. Leckie; an Indian Kite (*Milvus govinda*) from East Asia, presented by Capt. Murray; a Common Chameleon (*Chamæleon vulgaris*) from North Africa, presented by Mr. A. Dodd; a Diana Monkey (*Cercopithecus diana*), a Subcylindrical Hornbill (*Buceros subcylindricus*) from West Africa, received in exchange; a Macaque Monkey (*Macacus cynomolgus*) from India, five Peacock Pheasants (*Polyplectron chinquis*) from Burmah, deposited; twelve Common Teal (*Querquedula crecca*), twelve Garganey Teal (*Querquedula circia*), twelve Red-headed Pochards (*Fuligula ferina*), six Tufted Ducks (*Fuligula cristata*), four Shovellers (*Spatula clypeata*), two Common Pintails (*Dafila acuta*), two Common Widgeons (*Mareca penelope*), European, purchased; an Hybrid Markhoor (*Capra megaceros*), six Seven-banded Snakes (*Tropidonotus leberis*), born in the Gardens.

RECENT CONTRIBUTIONS TO THE HISTORY OF DETONATING AGENTS[1]

III.

NOBEL has observed that if, instead of making use of the most explosive form of gun-cotton, or trinitrocellulose, a lower product of nitration of cellulose (the so-called soluble or collodion gun-cotton) is added to nitro-glycerine, the liquid exerts a peculiar solvent action upon it, the fibrous material becoming gelatinised while the nitro-glycerine becomes at the same time fixed, the two substances furnishing a product having almost the characters of a compound. By macerating only from 7 to 10 per cent. of soluble gun-cotton with 90 to 93 per cent. of nitro-glycerine, the whole becomes converted into an adhesive plastic material, more gummy than gelatinous in character, from which, if it be prepared with sufficient care, no nitro-glycerine will separate even by its exposure to heat in contact with bibulous paper, or by its prolonged immersion in water, the components being not easily susceptible of separation, even through the agency of a solvent of both. As the nitro-glycerine is only diluted with a small proportion of a solidifying agent which is itself an explosive (though a somewhat feeble one), this *blasting gelatine*, as Nobel has called it, is more powerful not only than dynamite, but also than the mixture of a smaller quantity of nitro-glycerine with the most explosive gun-cotton, as the liquid substance is decidedly the most violent explosive of the two. Moreover, as nitro-glycerine contains a small amount of oxygen in excess of that required for the *perfect* oxidation of its carbon and hydrogen constituents, while the soluble gun-cotton is deficient in the requisite oxygen for its complete transformation into thoroughly oxidised products, the result of an incoporation of the latter in small proportion with nitro-glycerine, is the production of an explosive agent which contains the proportion of oxygen requisite for the development of the maximum of chemical energy by the complete burning of the carbon and hydrogen, and hence this blasting gelatine should, theoretically, be even slightly more powerful as an explosive agent than pure nitro-glycerine.

That such is the case has been well established by numerous experiments, but although this blasting gelatine may be detonated like dynamite by means of small quantities of confined detonating composition, when it is employed in strongly-tamped blast-holes, or under conditions very favourable to the development of great initial pressure, it behaves very differently from that material, or other solid though plastic preparations of nitro-glycerine, if the attempt is made to detonate it when freely exposed to the air or only partially confined. It not only needs a much more considerable amount of strongly confined detonating composition than dynamite and similar preparations do, to bring about a detonation with it under those conditions; but when as much as fifteen or twenty grains of confined fulminate are detonated in direct contact with it, although a sharp explosion occurs, little or no destructive action results, and a considerable portion of the charge operated upon is dispersed in a finely-divided condition.

In comparing the effects of these nitro-glycerine preparations with each other and with compressed gun-cotton and preparations of it, by detonating equal quantities quite unconfined upon iron plates, the results appear to establish great superiority, in point of violence, of action, or destructive effect, of the more rigid explosive agents (the gun-cotton preparations). Thus, employing iron plates 1 inch thick (supported upon an anvil with a central cavity), and 4 oz. of each material unconfined, the charges being all about the same diameter, exploded by detonators of equal strength, and simply resting upon the upper surface of the plate, compressed gun-cotton produced a considerable indentation of the upper surface of the plate, and long cracks in the lower surface; a species of nitrated gun-cotton, called tonite, produced a much shallower indentation, though still a very marked one, but did not crack the lower surface. Dynamite produced only a very slight impression upon the plate, and none could be detected by the eye on the plate upon which the blasting gelatine was exploded. The difficulties, brought out by past experience, which attend the contrivance of really comparative tests of the explosive power of such substances as those under discussion, is well exemplified by the foregoing results, which were influenced to the maximum extent by the physical characters of the several substances when thus applied, in a perfectly unconfined condition, so that the particles were free to yield to the force of the initiative detonation in proportion to their mobility. But, for this very reason, these experiments afford excellent illustration of the extent to which the development of detonation and the sharpness of its transmission through the mass is influenced not only by the inherent sensitiveness of the substance to detonation, but also by the degree of proneness of their particles to yield mechanically to the force of a blow as applied by an initiative detonation. Thus, although in comparing two substances of similar physical characters, compressed gun-cotton and compressed nitrated gun-cotton or tonite, the superiority of the pure compound over the mixture, in point of sharpness and violence of action, is well illustrated, a comparison of the result furnished by the weakest of the four explosive agents tried, viz., tonite, with that of the substance which should be superior to all the others in explosive force (*i.e.* the blasting gelatine) demonstrates the important influence which the comparatively great rigidity of the mass in the one case exerts in favouring the completeness and sharpness of its detonation in open air, and the great disadvantage under which the other explosive is applied, arising out of the plastic and therefore readily yielding nature of the material. But if, by exposure to a moderate degree of cold, this plastic nitro-glycerine preparation is made to freeze, its detonation upon an iron plate produces an indentation, as well as a destructive effect upon the lower surface of the plate, very decidedly greater than those furnished by the corresponding amount of pure compressed gun cotton. Similarly, the effect produced by the detonation of dynamite upon a plate of the kind used, is but little inferior to that of gun-cotton, and decidedly greater than that of tonite, if it is employed in the frozen condition.

A series of experiments has been made with cylinders of lead having a central perforation 1·3 inch in diameter extending to a depth of 7 inches and leaving solid metal beneath of a thickness ranging from 3·5 to 5·5 inches, according to the size of the cylinders used. These furnished results of considerable interest as illustrating the action of these several detonating agents. Charges of 1·25 oz. of each explosive substance were used throughout the experiments, and were placed at the bottoms of the holes. By the detonation of the charges the cylindrical holes in the lead were enlarged into cavities of a pear shape (and sometimes approaching the spherical form) of various diameters; in some instances the metal was besides partially torn open in a line from the bottom of the charge-hole to the circumference of the lower face of the cylinder; and in the case of some of the gun-cotton charges, the fissure in the metal in this direction was complete, the base of the block being separated from the remainder, in the form of a cone. In the first place the portions of the holes above the charges were simply left open; in the subsequent experiments they were filled up to a level with the upper surface, with dry, fine, loose sand, or with water. The dimensions of the cylinders were increased in successive experiments until, in the case of every one of the explosives used, the mass of metal was sufficiently great to resist actual fracture at the base of the cylinder. Under the condition of these experiments, more or less considerable resistance being opposed to the mechanical dispersion of the plastic explosive substances, their detonation was greatly facilitated, though even then, the holes in the lead blocks being left open to the air, some amount of the blasting gelatine evidently escaped detonation; the widening of the upper part of the charge-hole, in experiments of this nature made with the gelatine, indicated that detonation was transmitted to small portions dispersed in the first instance and in the act of escaping from the block. In all the experiments, whether the holes were left open or filled with sand or water, the effect produced upon the base of the block by the detonation of compressed gun-cotton, was considerably more violent than with the other explosive agents, indicating a sharpness of action which was only shared by the blasting gelatine when used *in a frozen state* in one of these experiments. The dimensions of the cavities produced by the gelatine were, at the largest part, considerably greater than those produced by the dynamite and nitrated gun-cotton (tonite), and slightly greater than those of the gun-cotton charges; but in the latter, the fracture of the base of the cylinder gave rise in most of the experiments to an escape of force, so that in these cases the effects of the detonation could not be well compared by measurements of the cavities. When the gelatine was converted by freezing into a rigid mass its superiority in explosive force even over compressed gun-cotton

[1] Weekly Evening Lecture at the Royal Institution, Friday, March 21, 1879. By Professor Abel, C.B., F.R.S. Revised by the Author. Continued from p. 45.

was well illustrated; the base of the lead block was all but blown out, the cavity produced was considerably the largest, and the suddenness and violence with which motion was imparted to the water tamping caused the top of the block also to be blown off in the form of a cone.

The difficulties attending the application of blasting gelatine, in some directions in which explosive agents are applied, on account of the uncertainty attending the development of its explosive force, even with the use of a comparatively powerful detonator, unless it be very strongly confined, has led to attempts to reduce its non-sensitiveness to detonation by mixing it with materials intended to operate either by virtue of their comparatively great sensitiveness or of their property as solids, of reducing the very yielding character of the substance, or in both ways.

Some of these attempts have been attended with considerable success. Thus the incorporation of about 10 per cent. of the most explosive form of gun-cotton or trinitrocellulose, in a very finely divided state, with the gelatine, renders it so much more sensitive that it can be detonated with certainty in the open air by means of the strongest detonating cap now used for exploding dynamite. This effect appears to be less due to the comparative sensitiveness of gun-cotton to detonation than to the modification effected in the consistency of the material, which, though still plastic, offers decidedly greater resistance to a blow than the original gummy substance. The particles of hollow fibre of the gun-cotton appear also to have the effect of absorbing small quantities of nitro-glycerine which are less perfectly united with the soluble gun-cotton than the remainder, and which, existing as they do in somewhat variable proportions in the gelatine, have occasionally an objectionable tendency to exudation, if the incorporation of the ingredients has been less perfect than usual. The substance, when modified as described, has no longer that great adhesiveness which is exhibited by it in the original state, and which renders it less easy to manipulate.

Lastly, its explosive force appears to be in no way diminished by this modification of its composition; on the contrary, its superiority in this respect to compressed gun-cotton becomes more manifest, as demonstrated by some of the experiments with lead blocks, while its action partakes of that sharpness peculiar to the detonation of the rigid gun-cotton, as indicated by the fissure of that part of the metal situated beneath the charge. Finely divided cotton fibre has a similar effect to trinitrocellulose in modifying the physical character and increasing the sensitiveness to detonation of the blasting gelatine, but its explosive force is, of course, proportionately reduced with its dilution with an inert substance.

Nobel has made the interesting observation that an addition to the blasting gelatine of small proportions of certain substances rich in carbon and hydrogen, which are soluble in nitro-glycerine, such as benzol and nitro-benzol, increases to a remarkable extent the non-sensitiveness to detonation of the original material; and this observation has led to experiments being conducted by engineer officers in Austria, with a view of endeavouring to convert the blasting gelatine into a material which should compete, as regards some special advantages in point of safety, with wet gun-cotton in its application to military and naval purposes, and especially as regards non-liability to detonation or explosion by the impact of rifle bullets. If boxes containing dry compressed gun-cotton are fired into from small arms even at a short range, the gun cotton is generally inflamed, but has never been known to explode. It is scarcely necessary to state that wet gun-cotton, containing even as little as 15 per cent. of water, is never inflamed under these conditions. On the other hand, dynamite is invariably detonated when struck by a bullet on passing through the side of the box, and blasting gelatine, though so much less sensitive than dynamite, behaves in the same way in its ordinary as well as in the frozen condition. The Austrian experiments indicated that the gelatine when intimately mixed with only 1 per cent. of *camphor*, generally, though not invariably, escaped explosion by the impact of a bullet, but that when the proportion of camphor amounted to 4 per cent. the material was neither exploded nor inflamed, though, in the frozen state, it was still liable to occasional explosion. These results were considered indicative of a degree of safety in regard to service exigencies, approaching that of wet compressed gun-cotton. The camphoretted gelatine still labours, however, under the disadvantage of being readily inflammable and of burning fiercely, and consequently of giving rise, like dynamite and dry gun-cotton, to violent explosion, or detonation, if burned in considerable bulk. Moreover, the camphoretted blasting gelatine is so difficult of detonation by the means ordinarily applied that a large initiative charge of a specially violent detonating mixture is prescribed by the Austrian experimenters as being indispensable to its proper detonation.

The action of camphor and of other substances rich in carbon and hydrogen in reducing greatly the sensitiveness to detonation of the preparation of soluble gun-cotton and nitro-glycerine is not to be traced to any physical modification of that material produced by the addition of such substances, and no satisfactory theory can at present be advanced to account for it on chemical grounds.

The camphoretted gelatine, like Nobel's original gelatine itself, may be kept immersed in water for a considerable time without any important change; the surface of the mass thus immersed becomes white and opaque, apparently in consequence of some small absorption of water, but no nitro-glycerine is separated, and on re-exposure to the air the material gradually assumes once more its original aspect. It has consequently been proposed to render the storage of blasting gelatine comparatively safe by keeping it immersed in water till required for use, but the test of time is still needed to establish the unalterableness of the material under this condition.

There can be little question that this interesting nitro-glycerine preparation, either in its most simple form, or modified in various ways, by the addition of other ingredients, promises, by virtue of its great peculiarities as a detonating agent, to present means for importantly extending the application of nitro-glycerine to industrial purposes; and it is not improbable that, through its agency, this most violent of all explosive agents at present producible upon a large scale may also come to acquire special value for important war-purposes.

It has been pointed out that the complete solidification, by freezing, of plastic preparations containing nitro-glycerine, such as dynamite and the blasting gelatine has the effect of facilitating the transmission of detonation throughout the mass under certain conditions of their applications, *i.e.*, when they are either freely exposed to air or not very closely or rigidly confined. But while, under circumstances favourable to the detonation of these substances, when in the frozen state, their full explosive force is thus much more readily applied than when they are in their normal (thawed) condition, the frozen substances are less sensitive to detonation by a blow or an initiative detonation. On the other hand, if subjected to the rapid application of great heat (as for example by the burning of portions of a mass of the explosive substance itself), a detonation is much more readily brought about with the frozen material than if it be in its normal condition. Thus a package containing 50 lb. of cartridges of plastic dynamite, when surrounded by fire, burned away without any indication of explosive action; on submitting 10 lb. of frozen dynamite to the same treatment, that quantity also burned without explosion, though at one time the combustion was so fierce as to indicate an approach to explosive action; but when the experiment was repeated on the same occasion with 15 lb. of frozen dynamite a very violent detonation took place after the material had been burning for a short time.

The following is offered as the most probable explanation of this result. When a mass of dynamite, as in these cartridges, is exposed to sufficient cold to cause the nitro-glycerine to freeze, it does not become uniformly hardened throughout, partly because of slight variations in the proportion of nitro-glycerine in different portions of the mixture composing the cartridge, and partly because unless the exposure to cold be very prolonged the external portions of the cartridges will be frozen harder or more thoroughly than the interior. It may thus arise that portions of only partially frozen or still unfrozen dynamite may be more or less completely inclosed in hard crusts, or strong envelopes, of perfectly frozen and comparatively very cold dynamite. On exposure of such cartridges to a fierce heat very rapidly applied, as would result from the burning of a considerable quantity of the material, some portion of one or other of the cartridges would be likely to be much more readily raised to the igniting or exploding point than the remaining more perfectly frozen part in which it is partly or completely imbedded. If the ignition of this portion be brought about (which it will be with a rapidity proportionate to the intensity of heat to which the cartridge is exposed), the envelope of hard frozen dynamite by which it is still more or less completely surrounded and strongly confined, will operate like the metal envelope of a detonator, in developing the initial pressure essential for the sudden raising of the more readily in-

flammable portion of the dynamite to the temperature necessary for the sudden transformation of the nitro-glycerine into gas, and will thus bring about the detonation of a portion of the cartridge, which will act as the initiative detonator to the remainder of the dynamite. On igniting separately, at one of their extremities, some dynamite cartridges which had been buried in snow for a considerable period, the lecturer has observed that, as the frozen material gradually burned away, very slight but sharp explosions (like the snapping of a small percussion cap on a gun nipple) occurred from time to time, portions of the frozen dynamite being scattered with some violence. It has come to his knowledge that small heaps of hard-frozen cartridges weighing altogether one pound have been detonated by igniting one cartridge which was surrounded by the remainder. These facts appear to substantiate the correctness of the foregoing explanation. They point to the danger of assuming that, because dynamite in the frozen state is less sensitive to the effects of a blow or initiative detonation, than the thawed material, it may therefore be submitted without special care to the action of heat, for the purpose of thawing it. Instances of the detonation, with disastrous results, of even single cartridges of frozen dynamite, through the incautious application of considerable heat (as for example by placing them in an oven, or close to a fire), have been, and are still, of not unfrequent occurrence, even though Mr. Nobel has insisted upon the application of heat through the agency only of warm water, as the sole reliable method of safely thawing dynamite cartridges.

While the sensitiveness to detonation of air-dry gun-cotton remains unaffected by great reduction in temperature of the mass, and while in this respect it presents advantages over nitro-glycerine preparations, wet gun-cotton becomes very decidedly more susceptible to detonation when frozen. Thus the detonation of gun-cotton containing an addition of from 10 to 12 per cent. of water is somewhat uncertain with the employment of 100 grains of strongly confined fulminate, and 200 grains are required for the detonation of the substance when containing 15 to 17 per cent. of water; but the latter in a frozen state can be detonated by means of thirty grains of fulminate, and fifteen grains are just upon the margin of the amount requisite for detonating, with certainty, frozen gun-cotton containing 10 to 12 per cent. of water.

The effects produced and products formed by the explosion of gun-cotton in perfectly closed spaces, both in the loose, and the compressed form, and by its detonation in the dry and the wet state, have been made the subject of study by Capt. Noble and Mr. Abel, the method of research pursued being the same as that followed in their published researches on fired gunpowder; results of considerable interest in regard to the heat of explosion; the pressures developed, and the products of explosion of dry and wet gun-cotton, have been obtained, which are about to be communicated to the Royal Society.

It may briefly be stated that the temperature of explosion of gun-cotton is more than double that of gunpowder (being about 4,400° C.); that the tension of the products of explosion, assuming the material to fill entirely the space in which it is fired, is considerably more than double that of the powder-products under the same conditions; that the products obtained by the explosion of dry gun-cotton are comparatively simple and very uniform under different conditions as regards pressure; that the products of *detonation* of *dry* gun-cotton do not differ materially from those of its explosion in a confined space, but that those furnished by the detonation of *wet* gun-cotton present some interesting points of difference. Messrs. Nobel and Abel are extending their investigations to the nitro-glycerine preparations.

The great advance which has been made within the last twelve years in our knowledge of the conditions which determine the character of the metamorphosis that explosive substances undergo, and which develop or control the violence of their action, finds its parallel in the progress which has been made in the production, perfection, and application of the two most prominent of modern explosive agents, nitro-glycerine and gun-cotton. Discovered at nearly the same time, less than forty years ago, the one speedily attained great prominence, on account of the apparent ease with which it could be prepared and put to practical use; a prominence short-lived, however, because the first, and somewhat rash, attempts to utilise it preceded the acquisition of sound and sufficient knowledge of its nature and properties. Even many years afterwards, when the difficulties attending its employment appeared to have been surmounted, the confidence of its most indefatigable partisans and staunchest friends received a rude shock, from which it needed the support of much faith and some fortitude to recover.

Meanwhile, the other substance, which now shares with it the honours of important victories won over gunpowder, continued to be generally regarded as a dangerous chemical curiosity, even for some time after its present position as one of the most important industrial products and useful explosive agents was being gradually but firmly secured for it, step by step, by the talent and untiring energy of a single individual.

Almost from the day of its discovery, the fortunes of gun-cotton continued to fluctuate, and much adversity marked its career, until at last its properties became well understood, and its position as a most formidable explosive agent, applicable on a large scale, with ease, great simplicity, and with a degree of safety far greater than that as yet possessed by any other substance of this class, has now become thoroughly established. Since the lecturer last discoursed on the properties of gun-cotton, seven years ago, this material has attained a firm footing as one of the most formidable agents of defence and offence. For all military engineering operations, and for employment in submarine mines and torpedoes, compressed gun-cotton, stored and used in the wet condition, has become the accepted explosive agent in Great Britain; within the last five years upwards of 550 tons have been manufactured for this purpose, and are distributed over our chief naval stations at home and abroad. Germany some years since copied our system of manufacture and use of gun-cotton; France has provided itself with a large supply for the same purposes, and Austria, where the acquisition of bitter experience of the uncertainty of gun-cotton in the earlier stages of history, naturally gave rise to a persistent scepticism regarding its present trustworthiness, appears now also about to adopt wet gun-cotton for military and naval uses.

But while the usefulness and great value of compressed gun-cotton in these important directions have been established, its technical application has made but slow progress as compared with that of the simple nitro-glycerine preparation known as dynamite, which, in point of cost of production and convenience for general blasting purposes, can claim superiority over compressed gun-cotton. Already in 1867 a number of dynamite factories, working under Nobel's supervision, existed in different countries; in that year the total quantity manufactured amounted to 11 tons; in another year the produce had risen to 78 tons; in 1872 it had attained to 1,350 tons. Two years afterwards the total production of dynamite was nearly trebled, and in 1878 it amounted to 6,140 tons.

There are as many as fifteen factories in different parts of the world (including a very extensive one in Scotland) working under the supervision of Mr. Nobel, the originator of the nitro-glycerine industry, and some six or seven other establishments exist where dynamite or preparations of very similar character are also manufactured.

How far the rate of production of dynamite will be affected by the further development of the value of Nobel's new preparation, the blasting gelatine, it is difficult to foresee, but there appears great prospect of an important future for this very peculiar and interesting detonating agent.

It is hoped that the subjects dealt with in this discourse afford interesting illustration of the intimate connection of scientific research with important practical achievements.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

DR. CARPENTER, Registrar of the University of London, announced his retirement from that office at the annual meeting of Convocation on Tuesday. A unanimous vote was passed, recognising his long and valuable services in the post which he had so long held.

THE recent retirement of Prof. Balfour from the Chair of Botany at Edinburgh has given rise to two changes in the Scottish professoriate. As his successor, our readers know, the Curators have appointed Dr. Alexander Dickson, the able Professor of Botany in the University of Glasgow. The botanical class has always been popular at Edinburgh, Dr. Balfour's students having recently numbered, we believe, upwards of 350. The class-room of the new professor, also, is so crowded that many of the auditors can hardly find standing-room, large numbers having been unable even to gain admission. Prof. Dickson is

therefore under the necessity of lecturing twice a day. His retirement from Glasgow College has opened the way for a young botanist of great promise, Dr. I. Bayley Balfour, son of the veteran professor at Edinburgh, who has been appointed by the Crown to the vacant chair. Dr. Balfour took the degree of Doctor of Science in Botany some years ago with great distinction at Edinburgh. He was selected by the Council of the Royal Society to accompany the recent Transit of Venus Expedition to Rodriguez for the purpose of making a scientific examination of that island. As the result of his researches, besides the report on the natural history, which he has sent in to the Royal Society, he has produced an excellent paper on the genus *Halophila*. Having had considerable experience in class-work under his father, as well as under Professors Huxley and Sir Wyville Thomson, he enters on his new duties with many advantages. Whether as an original investigator or as a successful teacher, he will, we doubt not, fully sustain the reputation of the Glasgow University.

We are glad to notice that the School Board for London have decided that it would be expedient to include the elements of natural science among the recognised subjects of class examination. The object of this resolution is to transfer what is called elementary science from the category of specific subjects into the category of class subjects. At present there is little inducement for pupils to take science subjects, nor will there be until it be included in the regular course of instruction in elementary schools. We hope the memorial which the Board is to prepare will be treated with the attention it deserves.

SOCIETIES AND ACADEMIES

London

Royal Society, May 8.—"On the Sensitive State of Electrial Discharges through Rarefied Gases." By William Spottiswoode, P.R.S., and S. Fletcher Moulton, late Fellow of Christ's College, Cambridge.

It has frequently been remarked that the luminous column produced by electric discharges in vacuum tubes sometimes displays great sensitiveness on the approach of the finger, or other conductor, to the tube. This is notably the case when with an induction coil a very rapid break is used, or when with any constant source of electricity an air-spark is interposed in the circuit leading to the tube. The striking character of the phenomena, and the opportunity which they showed for affecting the discharge from the outside during its passage, led the authors of this paper to consider that a special examination of this sensitive state would be desirable.

All the circumstances under which sensitiveness is produced appear to agree in requiring, first, that there should be a rapid intermittance in the current leading to the tube; and secondly, that the individual intermittent discharges should be small in quantity and extremely brief, if not instantaneous, in duration. Both these requirements are fulfilled by the methods used in the present investigation, viz., a Holtz machine with a suitable air-spark between the machine and the tube, and a small coil with a rapid break.

If a conductor be made to approach a tube conveying a sensitive discharge, due to an air-spark in the positive branch of the circuit, a series of effects is produced, of which the feeblest and the strongest are the most pronounced. The transition from one to the other is so rapid that the intermediate phases may be easily overlooked. In the first case, the luminous column is repelled by the conductor; in the second it is broken into two parts which stretch out in two tongues towards the point on the tube (P) nearest the conductor, while a negative halo appears between them.

That these effects are due to the inductive action of the conductor, or more particularly to re-distributions of electricity in it, co-periodic with the air-spark, and not to any permanent charge, is shown by the following experiments. A non-conductor, whether charged or not, is without effect. The effect of a conductor increases with its size or capacity, and with its proximity to the tube, until the fullest effect (viz., that given by an earth connexion) is produced. That the effects are not due to electrodynamic, or to magnetic action, is shown by the fact that a coil of wire produces the same result, whether the ends be joined or not. The effects of an iron core and helix with open ends are often comparable with, and sometimes equal to, those when the ends, being connected with a battery, the whole becomes an electro-magnet. The effect upon the interior is, in fact, due to the relief given by the conductor to the electric tension on the outer surface of the tube and the space around it, caused by the individual discharges.

Instead, however, of connecting a point (P) on the tube with a large conductor or with earth, we may connect it with one or other terminal of the tube. And a further study of the subject shows that all the phenomena due to action from without may be produced by means of one or other of these connexions. Connexion with the non-air-spark terminal gives the relief effects described above; connexion with the air-spark terminal gives another set of effects. Of these the feeblest has the appearance of attraction, while the strongest shows an abrupt termination of the positive column in the neighbourhood of the point (P), followed by a negative halo, and then by a recommencement of the positive column in the direction of the negative terminal. Each of these sectional discharges is in fact independent and complete in itself, and they are due to impulses of positive electricity thrown into the tube from the air-spark. At the positive terminal these impulses are thrown directly in; at the points of connexion they are due to induction, *ab extra*. The negative part of what was originally neutral meets the positive column, and satisfies it as it arrives, while the positive leaps forward to meet the negative due from the negative terminal.

The effects above described need not be confined to a single patch or ring of conducting material placed upon the tube; but they may be produced many times over in the same tube by a series of rings arranged at suitable distances. By this means the column may be broken into a series of sections, all terminating with well-defined configurations towards the negative end, and having greater or less length, according to the position of the rings. In the paper itself, arguments are there brought forward showing that these sectional discharges represent striæ not merely in their appearance, but also in their function and structure. But the discussion could hardly be produced within the limits of an abstract.

Returning from the digression about striæ, the authors next give evidence, derived mainly from the revolving mirror, and from the discharges of a partially charged Leyden jar, for the following conclusion: That the passage of the discharge occupies a time sufficiently short in comparison with the interval between the discharges to prevent any interference between successive pulses. Certain experiments are then described which indicate that the discharge is effected, under ordinary circumstances, by the passage through the tube from the air-spark terminal of free electricity, of the same name as the electricity at that terminal. In the case of an induction coil, where the air-spark must be considered as existing at both terminals, there is evidence of a *neutral zone*, where the sensitiveness disappears. The position of this zone may be altered by damping the impulses at either terminal; or it may be abolished by connecting one terminal with earth. The impulses may even be so distributed as to divide electrically a single tube into three sections, the two extremes presenting visible discharges, with a dark section between them.

Looking at all these phenomena from an opposite point of view, we may, by means of the relief effects, determine the terminal from which a discharge proceeds, and the distance to which it reaches without provoking a response from the other. And through these considerations, together with others detailed in the paper, the authors are led to the conclusion that the discharges at the two terminals of a tube are in the main independent, and that they are each determined primarily by the conditions at their own terminal, and only in a secondary degree by those at the opposite terminal.

In illustration of this view, an account is then given of the production of unipolar, positive, or negative discharges in a tube. In such cases, the discharge being insufficient of itself to pass through the tube, returns by the way by which it entered.

This closes a series of experiments, the result of which is that the discharges from the two terminals can be made of equal intensity, or of any required degree of inequality; or the discharge can be made to issue from one terminal only, the other acting only receptively; or it can be made to return into its own terminal, while the other takes no part in the discharge; or, finally, the two terminals can be made to pour out independent discharges of the same name, each of which returns to its own terminal.

Having traced the relation between the two parts of the discharge, and having found means for controlling their range and influence, the authors were led to inquire whether there be any experimental evidence of the state of the tube during the occurrence of the discharge. Some experiments with two pieces of

tinfoil of unequal size placed near the ends of the tube and metallically connected, and others with a strip of tinfoil placed along the tube, all gave effects showing that the discharge cannot be simultaneous throughout the tube. The phenomena appear to require for their interpretation that, in front of the pulse coming from the (positive) air-spark terminal, there is, during the interval between the pulses, a rising negative potential. This is entirely swept out by the pulse as it advances along the tube, after which the process is repeated. The condition of things behind the pulse is more difficult to determine, but an experiment with the telephone gives reason to think that parts of the tube nearer to the non-air-spark end are in a condition to demand relief, before those nearer to the air-spark terminal have ceased to require it. And on this account the discharge may, perhaps, be more nearly represented by a lazy tongs than by a bullet.

How far the results obtained from the sensitive state are applicable to ordinary discharges is a question which cannot yet be definitively answered. But the marked similarities in the phenomena, and the predisposing circumstances of striation or non-striation, as well as in the terminal peculiarities of the two kinds of discharge, point strongly to the conclusions that all vacuum discharges are "disruptive"; and that sensitive differ from non-sensitive discharges mainly in the scale of the discontinuity due to the disruptiveness, causing a difference between the two classes of phenomena analogous to that between impulsive and continuous forces in dynamics.

Mathematical Society, May 8.—Mr. C. W. Merrifield, F.R.S., president, in the chair.—Messrs. A. J. C. Allen and E. Anthony were elected Members.—The following communications were made:—On the complex whose lines join conjugate points of two correlative planes, Dr. Hirst, F.R.S.—Note on a geometrical theorem connected with the function of an imaginary variable, Prof. Cayley, F.R.S.—Some definite integrals, the late Prof. Clifford, F.R.S.—A method of constructing, by pure analysis, functions X, Y, &c., which possess the property that $\int X\,Y d\sigma = 0$, and such that any given function can be expanded in the form $\alpha X + \beta Y + \gamma Z + \ldots$, Mr. E. J. Routh, F.R.S.—The numerical calculation of a class of determinants, and a continued fraction, Mr. J. D. H. Dickson.—On the inscription of the regular heptagon, Rev. Dr. Freeth.

Zoological Society, May 6.—Prof. W. H. Flower, F.R.S., president, in the chair. A letter was read from Mr. E. L. Layard, F.Z.S., relating to the localities of certain species of Fruit-Pigeons (*Ptilopus*) of the South Pacific Islands.—Prof. Flower, F.R.S., exhibited and made remarks on a drawing of a British Cetacean (*Delphinus tursio*), taken from a specimen captured near Holyhead in 1878.—A communication was read from Mr. Gerard Krefft, giving the description of a supposed new form of insectivorous Bat, of which a specimen had been obtained on the Wilson River, Central Queensland.—The Rev. Canon Tristram, C.M.Z.S., read a description of a new species of Wood-pecker, from the Island of Tyzu Sima, near Japan, which he proposed to name after its discoverer, *Dryocopus richardsi*.—A communication was read from Mr. F. Moore, F.Z.S., containing the descriptions of new genera and species of Asiatic Lepidoptera Heterocera. Eleven new genera were characterised and ninety new species described.—Mr. G. French Angas, C.M.Z.S., read the descriptions of ten new species of shells of the genera *Axinæa* and *Pectunculus*.—A communication was read from Mr. W. A. Forbes, F.Z.S., on the anatomy of the African Elephant, based on the facts observed during a dissection of a young female of that species during the last winter. The structures of the thoracic, alimentary, and urino-genital viscera of this species were described, and compared with the previously published accounts of those of both the Indian and African species of Elephant. The most important differences observed were those displayed in the liver and female organs, but on the whole were not of such a nature as to make it advisable, in the author's opinion, to separate *Loxodon* as a genus from *Elephas* proper.—A paper was read by Mr. F. Jeffrey Bell, F.Z.S., on the question of the number of anal plates in the Echinoderms of the genus *Echinocidaris*.

Geological Society, April 30.—Henry Clifton Sorby, F.R.S., president, in the chair.—Alfred Stanley Foord was elected a Fellow of the Society.—The following communications were read:—A contribution to the history of mineral veins, by John Arthur Phillips, F.G.S. In this paper the author described the phenomena of the deposition of minerals from the water and steam of hot springs, as illustrated in the Californian region, referring especially to a great "sulphur bank" in Lake County, to the steamboat springs in the State of Nevada, and to the great Comstock lode. He noticed the formation of deposits of silica, both amorphous and crystalline, inclosing other minerals, especially cinnabar and gold, and in some cases forming true mineral veins. The crystalline silica formed contains liquid-cavities, and exhibits the usual characteristics of ordinary quartz. In the great Comstock lode, which is worked for gold and silver, the mines have now reached a considerable depth, some as much as 2,660 feet. The water in these mines was always at a rather high temperature, but now in the deepest mines it issues at a temperature of 157° Fahr. It is estimated that at least 4,200,000 tons of water are now annually pumped from the workings; and the author discussed the probable source of this heat, which he was inclined to regard as a last trace of volcanic activity.—*Vectisaurus valdensis*, a new Wealden Dinosaur, by J. W. Hulke, F.R.S. The characters presented by the genus *Vectisaurus* were stated to be as follows:—Ilium with a long compressed antacetabular process, having its greatest transverse extent in a vertical plane, and strengthened by a strong ridge produced from the sacral crest. Vertebræ in anterior dorsal region having opisthocœlous centres, their lateral surfaces longitudinally concave, transversely gently convex, meeting below in a blunt keel.—On the Cudgegong diamond-field, N.S.W., by Mr. Norman Taylor.—On the occurrence of the genus *Dithyrocaris* in the lower carboniferous, or calciferous sandstone series of Scotland, and on that of a second species of *Anthrapalæmon* in these beds, by R. Etheridge, Jun., F.G.S.

CAMBRIDGE

Philosophical Society, May 5.—A communication was made to the Society by Prof. T. McK. Hughes, on the relation of the appearances of life upon the earth to the known breaks in the continuity of the older sedimentary rocks. In his introductory remarks the author explained the manner in which he believed the transference of the area of the growth of sediment took place by gradual depression on one side and elevation on the other, and pointed out that there was stratigraphical evidence of the earlier commencement of the accumulation of a continuous series in one area than another, and that often the direction of the movements could be inferred. To the compulsory migration of species consequent upon these movements he attributed the extinction of those that could not adapt themselves to the new circumstances, the appearance of the colonies described by Barrande, and also the gradual introduction of new forms of life throughout the whole of the sedimentary rocks. The principal part of the paper was upon the last question, the author holding that it was only reasoning in a circle to define formations palæontologically and then to speak of the incoming and outgoing of species as nearly coincident with the beginning and end of the formation. He classified the whole sedimentary series on the principle of grouping together all the sediment continuously deposited in any one area, and indicated by corresponding intervals the period during which there was in that area denudation only, the deposition of the denuded material necessarily going on elsewhere. Then, giving an analysis of the palæontology of the older rocks, he showed that the various forms of life came in gradually as compelled to move, and as their travelling powers allowed them, from adjoining areas where local conditions had become unfavourable, pointing out that they did not generally first appear at the beginning or disappear at the close of any series of continuous deposits, but that new forms kept turning up all through, and that after a long interval, whether measured by denudation or deposition, about the same kind and amount of palæontological change had occurred, the chances being that in so long a time geographical changes had taken place in the surrounding district. He showed that thus the palæontological confirmed the stratigraphical evidence with regard to the persistence of continental as well as of oceanic areas, as the sequence of life on the earth required that there could never have been an interruption in the continuity of suitable land and water. He appealed to physicists to tell us whether chiefly to the transference of such great masses of material always to the coast lines of continents, or to secular cosmical action, or to both, we should refer this persistent creeping of earth folds in various directions at different times.

PARIS

Academy of Sciences, April 28.—M. Daubrée in the chair.—The following papers were read:—On the electric light,

by M. Jamin (see last week's NATURE).—On criticism of experiments undertaken to determine the direction of the pressure in oblique arches, by M. de la Gournerie.—On the choice of moduli in hyperelliptic integrals, by M. Borchardt.—The president of the Venus Transit Committee presented fascicle B of "Documents relating to Measurement of Photographic Negatives." This includes a thorough discussion of the measurements at St. Paul's Island.—Report on a note relative to the embankment of the Tiber at Rome, presented by M. Dausse. Instead of trying to obviate inundations by high quay walls, this engineer recommends a partly natural deepening of the bed, securing continuous navigation. He bases his arguments on results of a system adopted on the Po and elsewhere, in which the river is narrowed by submersible dykes (within insubmersible ones), and by its thus increased velocity insures a sufficient draught of water. In flood-time the water-level is lower than formerly, and the expanded river gives rich deposits in the larger bed beyond the submersible dykes.—On the electrical inscription of speech, by M. Boudet de Paris. A very sensitive microphonic transmitter is used, in which the carbons are simply held in contact by a small piece of paper folded in the form of V. The receiving telephone has diaphragm and cover removed, a spring fixed at one end on the wood, and at the other end (to which is added a small piece of soft iron), resting on the magnet; a light bamboo style with whalebone extremity is attached to the spring, and gives instructive traces on decalcomanic paper.—Observation of the periodic comet II., 1867 (Tempel), made by M. Tempel at Florence Observatory.—On a new form of co-ordinates in the problem of two bodies, by M. Gyldén.—On a class of non-uniform functions, by M. Picard.—Theoretical and experimental demonstration of the following definition of temperature: Temperature is represented by the length of calorific oscillation of the molecules of a substance, by M. Pictet. He verifies these two laws: 1. The higher the points of fusion, the shorter are the molecular oscillations. 2. The temperatures of fusion of solids corresponding to equal lengths of oscillation, and the product of the lengths of oscillation by the temperatures of fusion, should be a constant number for all solids.—Siren with electromagnetic regulator, by M. Bourbouze. An improvement on an apparatus described December 18, 1876; with a pinion and double rack he can simultaneously bring near both electromagnets to the copper disk or remove them, obtaining any note in the siren.—On a mode of continuous registration of the direction of the wind, by M. André. This instrument, constructed by M. Redier, is used at Lyons Observatory.—On the present state of Vesuvius, by M. Semmola. The large crater of 1872 is almost wholly filled up; the new cone of eruption has grown so that it is now on a level with the old crater, and will soon be above it. Lavas are sometimes poured out on the north side, and seen from Naples. Fumeroles of lava are very frequent and lively on the interior walls of the old crater; they are all acid. (The products, &c., are described.)—On the laws of dissociation, by MM. Moitessier and Engel. From experiments with hydrate of chloral they find (*inter alia*) that the dissociation of a substance whose two components are volatile takes place even in presence of one of the products of the dissociation, so long as the tension of this product does not exceed that of dissociation of the substance at the temperature operated with.—On the determination of glucose in the blood, by M. Cazeneuve.—Facts bearing on the history of beer yeast and alcoholic fermentation; physical and physiological action of some saline substances on normal yeast, by M. Bechamp. The action of acetate of soda is specially studied.—On the form of muscular contraction of the muscles of the crayfish, by M. Richet. Between the principal muscles, that of the tail and that of the claw, there is as considerable a difference as between smooth and striated muscles in vertebrates.—The cochineals of the young elm, a new genus, *Ritsemia pupifera*, by M. Lichtenstein.—Why one sometimes finds plants of limestone associated with those of silica, by M. Contejean.

May 5.—M. Daubrée in the chair.—The following papers were read:—On the heat of formation of cyanogen, by M. Berthelot. Cyanogen (like acetylene and bioxide of nitrogen) is a substance formed with absorption of heat. The mean number, 132·3 cal., was obtained for its heat of combustion (the equivalent (C_2N = 26 grammes); this number is somewhat less than Dulong's.—On some derivatives of durol (α-tetramethylbenzine), by MM. Friedel, Crafts, and Ador.—Experiments for determining the direction of the pressure in a slanting arch, by M. de la Gournerie.—On the transformations of the second order of hyperelliptic functions, which, applied twice successively produce duplication, by M. Borchardt.—On the crystals extracted from cast iron by ether or petroleum, by Prof. Lawrence Smith. The cast iron is treated in a finely divided state. It yields a soluble matter consisting chiefly of sulphur, and crystallising in fine needles, like the matter which the author has separated from meteoritic graphite. M. Berthelot stated he had got like crystals by treating artificial or natural sulphides with ether or alcohol, and he attributed the matter to chemical action of the sulphur on the hydrocarbonised solvent. The results inspire reserve in conclusions as to pre-existence, in meteorites, of those crystallisable hydrocarbonised matters which are capable of extraction by organic solvents.—M. Daubrée presented a memoir by M. Abich, on the production and geotechnic conditions of the naphtha region near the Caspian.—Mr. MacCormick was elected correspondent for the section of Rural Economy, in room of the late M. Chevandier de Valdrôme.—Reflex effects produced by excitation of the sensitive fibres of the pneumogastric and the superior laryngeal on the heart and vessels, by M. François-Franck. The effects are moderation of the heart's action conjointly with constriction of the vessels.—Effects of sulphide of carbon on the radicular system of the vine, by M. Boitean. He points out certain evils connected with this mode of treatment. The sulphide destroys organic substances which are in its most concentrated atmosphere. Injections should be made 30 or 35 ctm. from the stem, and combined so that there should be two (of 10 grammes) per square metre.—Geometrical determination of umbilici of the surface of the wave, by M. Mannheim.—On the equivalence of algebraic forms, by M. Jordan.—On the calculation of perturbations, by M. De Gasparis.—On a theorem of dynamics, by M. Siacci.—On the thermal formation of siliciated hydrogen, by M. Ogier. He tried to determine the heat of combustion by means of free oxygen; whence he finds the union of $Si + H_4$ to be accompanied by a liberation of heat = + 24·8 cal., which is near the heat of formation of marsh gas (+ 22 cal.).—On the limit of separation of alcohol and water by distillation, by M. Le Bel. Ninety-seven per cent. was attained.—On a new isomer of angelic acid, by M. Duvillier.—Transformation of camphic acid into camphor, by M. De Montgolfier.—On the contractility of blood-capillaries, by M. Rouget. In all vertebrates a contractile coat of the same type, modified only in the number of its elements, envelopes the whole system of vascular blood-canals, including the heart and the capillaries. Contractility (modified only according to region) is an essential property of all the system.—On the action of salts of strychnine on gasteropod molluscs, by M. Heckel. These animals show a remarkable immunity as regards salts of strychnine. As in vertebrates, the degree of injuriousness of the poison is in inverse ratio of the animal's weight. The toxical phenomena are of the same order as in higher animals, *i.e.*, strychnine is a poison of the nervous system (tetanising).—On the *Haptophrya gigantea*, a new opaline of the intestine of anouran Batrachians in Algeria, by M. Maupas.—Artificial reproduction of native carburetted iron of Greenland, by M. Meunier.

MILNE'S CRYSTALLOGRAPHY

Notes on Crystallography and Crystallophysics. By John Milne, F.G.S. (London: Trübner and Co., 1879.)

THAT two little treatises should have appeared, written at so near a date the one to the other as Mr. Gurney's and Mr. Milne's introductory tracts on crystallography, shows that there is at least some want at last beginning to be felt for the means of studying that important but somewhat neglected science.

And it is suggestive of some singular reflections that one of these little treatises should come from Japan written by one of that teaching body at Yedo, of which Prof. Perry is a distinguished member.

Is there a demand springing up among the subjects of the Mikado for branches of knowledge which have hardly obtained a footing in institutions in which scientific training is given in Great Britain? Or is it that the Japanese have enticed to their colleges Englishmen who are so far ahead of their colleagues at home, that they are less trammelled by routine, and endeavour in the instruction they give to the youth of Japan to work out a more complete and comprehensive curriculum for the student of chemical science and physics than is recognised at home? Whatever be the cause, we have, in Mr. Milne's little treatise as we had before in Mr. Gurney's, an attempt to supply an educational want. We must award to Mr. Milne all the credit which is his due for the intention this attempt involves, and for his courage in undertaking it, with what was apparently a small and inadequate equipment either in previous study or in the literary material necessary for making his treatise thorough and worthy of the purpose that suggested it. The book is concise and its form fairly well planned; and if our praise cannot be extended to the execution of that plan the circumstances under which the little volume has been produced have to be considered in extenuation of the dispraise. But in criticising it, it is essential to consider its seventy pages solely on their merits. Like Mr. Gurney, Mr. Milne follows Prof. Miller's system of crystallographic notation, and endeavours to make clear the simplicity and elegance of that system. His first line, however, in explanation of the system, the sixth line of his Introduction, is, to say the least, infelicitous. "In this (Miller's) system," he says, "the symbols of a face consist of three whole numbers, each of which invariably refer to the same axes;" a sentence in which are compendiously represented the faults of the book, faults due partly to inaccuracy of mathematical conception, and partly to a mode of employing the English language, for which perhaps some excuse is to be found in a long residence in Yedo, but which surely one of the three home-editors, Mr. T. Davies, Mr. H. Woodward, and Prof. Morris, might have taken the liberty of correcting.

What Mr. Milne intended to convey in the above ungrammatical sentence was, of course, that the symbol for a plane is constituted by three whole numbers termed indices, which may include one or two zeros; the particular axis to which an index has reference being given by the position of the index in the symbol. If Mr. Milne would, for instance, consider the application of his statement to the symbols for the faces y, y', &c., of the crystal of cuprite, which he discusses on p. 27, and where by the by he makes the blunder in his result of putting (015) for (051), he would find that his statement amounts to the assertion that these two last symbols are identical, an assertion that would reduce the system of Miller to all the ineptitude of that of Naumann.

In deducing on p. 16 the symbol of a zone from the symbols of the planes belonging to it the author proceeds on the tacit assumption that he has rectangular axes to deal with, thus leaving unexplained the case of crystals belonging to systems referred to oblique axes; and these form a large majority of the known crystals.

In his mode of treating the problem by algebraic geometry in the last paragraphs on p. 17 he is certainly not to be congratulated.

It is from this p. 17 that one begins to find the hopelessness of this little book fulfilling, in its present crude form, the purpose its author proposes for it; that, namely, of making the simple system of F. Neumann and Miller intelligible either to the student slenderly equipped with mathematical knowledge, or to the votary, too often the partizan of the system of K. Naumann.

For it is evident that Mr. Milne has been unfortunate in his English editors. Mr. T. Davies, a gentleman universally esteemed for his personal character as well as for a very complete familiarity with minerals and rocks, obtained by the daily handling and scrutiny of them during twenty years of service in the British Museum, undertook, it seems, to pass through the press the little book of which copies lithographed by a Japanese native had been sent home to him and to others by Mr. Milne. If Mr. T. Davies had enlisted the aid of some one who possessed a rudimentary knowledge of algebra and plane trigonometry he might have saved Mr. Milne's little book from being useless. Then probably $\infty - 01$; $\infty - 10$; $11 - \infty$ would have been written $0 \times 0 - 0 \times 1$, &c., and would have been intelligible, and such a misprint as that on p. 21, "$\therefore$ (112) being (*sic*) the indices of the plane at $\perp s$ to [111] and [110]," might have been avoided. Of course a plane $\perp^r$ to [111] and [110] is $(\bar{1}10)$ or $(1\bar{1}0)$ and not (112); but Mr. Milne meant to write the two zones as $[11\bar{1}]$ and $[\bar{1}10]$. Misprints of this serious kind are very numerous; other instances are (loh) for $(lo\bar{h})$, (orq) for $(or\bar{q})$, or $(p - s)$ for $o, r(p - s)$ on p. 22; Wvw for UVW on p. 24; [312] twice for $[\bar{3}12]$ on p. 26; the frequent omission of brackets where they are necessary: for instance, $a^2kr - lq$ instead of $a^2(kr - l\bar{q})$ on p. 17; and these are the sort of errors which puzzle a student who is not a fair mathematician, precisely the student for whom the book is meant, since any one possessed of a little mathematical knowledge would naturally prefer to have recourse to Miller's Tract on Crystallography, a book of the existence of which Mr. Milne seems to be unaware, to judge from a note on p. 34. In a treatise on a science which presents to the student novel forms of notation the want of even the most elementary acquaintance with algebra that has allowed the introduction into the type, of

a comma to represent the sign of multiplication in almost every equation, invests the expressions with a hopeless obscurity; what for instance would a young student fresh from a little algebra make of the expression (p. 30), cos PC = cos PA, cos CA + sin PA, sin CA, cos PAC whence PC? Mr. Milne's editors and not Mr. Milne are of course to blame for this, though most of the other mistakes alluded to are his own.

In a chapter on the projection of poles by the stereographic method Mr. Milne gives a proposition for finding a pole [he means the projection of a pole] at given angular distances from two poles lying on the circle of projection, which is only a special and simple case of the more general problem. The description of the process is entirely unintelligible. If, however, the meaning be puzzled out from the figure it would seem that Mr. Milne is proposing a construction simple and ingenious, although to obtain it he has to combine the orthographic and stereographic projections. His editors might have saved him from using the expression "two half-hemispheres" on p. 38, if not also from the statement that the monosymmetric or monoclinic system can present eight faces for a single form. The chapter on crystallophysics is very unsatisfactory; after one's expectations of somewhat transcendental physics have been raised by being told that for the correlation of the phenomena produced by crystals with crystal-structure, "the most valuable hypothesis would probably be that of molecular vortices," one is certainly surprised to be told that in the orthorhombic, monoclinic, and triclinic systems "there are two optic axes or directions of double refraction"—or again, that "sections in triclinic crystals cut perpendicularly to the optic axes when viewed in a polariscope show a series of rings round each axis. Between the axes these are drawn together and may meet to form a lemniscate." One is inclined to ask whether Mr. Milne has a distinct idea as to what a lemniscate curve is, and how he cuts the section presenting these phenomena?

In speaking of heat conductivity again, the author places the rhombohedral and orthorhombic systems together in one category, and the tetragonal system in another. The errors, often arising in carelessness but sometimes in ignorance, to which these criticisms apply, have been selected merely at random. It has been necessary, however, to make these criticisms in the interest of the student, who might be repelled from a subject when he finds what should be a simple statement apparently untrue or unintelligible, whether on account of misprints or of obscurity in the language, in the thought, or in the author's method of demonstration. But having performed this duty to the student of a beautiful but much neglected science it would be ungenerous to a teacher in far Japan, not to point out that it is still within his power by recasting his little volume to fill a decided gap in our elementary scientific literature. He has the courage and the ability, he needs only a little more familiarity with the subject, a good deal more caution, and perhaps somewhat more of modesty, to enable him to fulfil the not very ambitious purpose he laid down for himself when he sent his little work to be published in England.

N. S. M.

MATHEMATICAL PROBLEMS

I. *Mathematical Problems on the First and Second Divisions of the Schedule of Subjects for the Cambridge Mathematical Tripos Examination.* Devised and arranged by Joseph Wolstenholme, M.A. Second Edition, greatly enlarged. (London: Macmillan and Co., 1878.)

II. *Solutions of the Cambridge Senate-House Problems and Riders for the Year* 1875. Edited by A. G. Greenhill, M.A. (Same Publishers, 1876.)

III. *The Same for the Year* 1878. Edited by J. W. L. Glaisher, F.R.S. (Same Publishers, 1879.)

IV. *Graduated Exercises in Plane Trigonometry.* Compiled and arranged by J. Wilson, M.A., and J. R. Wilson, B.A. (Same Publishers, 1879.)

V. *Geometrical Deductions, Riders, and Exercises, based upon Euclid, Books I.—IV.* (Stewart's Mathematical Series, 1878.)

A COMMON purpose pervades these five works, viz., that of affording practice and aid in the solution of mathematical problems. Prof. Wolstenholme, with a marvellous versatility which has long placed him in the foremost rank of "ten-minute conundrum" makers, sends forth a volume (I.) which now contains 2,815 problems in place of the 1,628 which he published in 1867. Further, his book has increased in all the directions in which it is possible for a book to grow, and the number of valuable hints scattered throughout the volume has been greatly enlarged. Dipping into the book here and there we are fain to cry out "Prodi-gi-ous!" with worthy Dominie Sampson, and to think this problem-compelling Briareus ever

> "Agitates his anxious breast,
> In solving problems mathematic."

We have long used the earlier work with profit to ourselves, and, we believe, to the advantage of our pupils preparing for Cambridge scholarship examinations; this new edition is an improvement upon the old, and in its line seems now perfect. What we would much like to have is Prof. Wolstenholme's solutions of his questions, but we fear the public, needed for the purchase of such a work, is not yet in existence. Doubtless there are many errors in the text, but these can only be found out by a free and long-extended use; however, we have noted in question 443, for the second $\cos^3\theta$ read $\sin^3\theta$; question 925, for a ? $2a$; p. 192, lines 2, 5, put − before Δ.

In the volumes II., III., we have a welcome revival of a fashion which has of late years died out; it never prevailed to any great extent, but its occurrence was generally traceable to the influence of some one or two enthusiasts, who, for the benefit of junior students, were willing to put upon record neat solutions of elegant problems, not counting the cost of publication. Such collections as these are especially valuable, and the volumes before us seem quite equal to their predecessors in the same field. A novelty in III. is the publication of additional remarks on some of the questions. For instance, a concise general statement of the method of least squares is given on pp. 162-169; on p. 8 is a note on circulating decimals, and similar notes occur elsewhere. In this work (III.) we have detected several small errors, p. 13 line 14 insert − before $\frac{3}{16}a^2$; p. 14

there are three errors; p. 147, line 7, dele "is *r*," there are two other errors on this page; p. 187 we have a vague reference to Boole's Differential Equations, and a misprint lower down; there are other minor errors easily detected, but when correcting pp. 114 to 116, somebody must have had his eyes shut at times or he would not have passed such a number of clerical errors.

In IV. we have a fresh work, well adapted for the higher forms in schools, though the examples are in some cases difficult. There are good notes, and the whole book may be recommended to students reading for scholarship or for college terminal examinations. We could put our finger upon many a mistake easily detected by an advanced student, so that we should advise junior pupils not to spend too long a time upon the questions if they do not succeed in getting the same answer as is given in the text. In making this statement we are bound to say that the number of mistakes seems to be no greater than is almost inevitable in a first edition.

The manual V. contains "more than 160 deductions which have been set at public examinations, worked out in full as examples, together with a collection of specimen examination papers, which have been set at the examinations, Cambridge Mathematical Tripos, London University Matriculation, &c." This fuller title gives a good idea of the scope of the work: it aims at doing for junior students what is done for higher students by McDowell's exercises on Euclid and in Modern Geometry. We have only been able to look into the book casually; we have found the parts so examined correct and put in such a way that a lad acquainted with the text of Euclid ought to have no difficulty in following the proofs here given. The student has to draw his own figures. The printing is good and so done as to assist the reader in his work. From the initials attached to the preface we should infer that the compiler is Mr. A. T. Fisher, whose "Book of Algebra" in the same series we commended, at the time of its publication, in these columns.

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts. No notice is taken of anonymous communications.*

[*The Editor urgently requests correspondents to keep their letters as short as possible. The pressure on his space is so great that it is impossible otherwise to ensure the appearance even of communications containing interesting and novel facts.*]

Spectrum of Brorsen's Comet

I HAVE to thank Dr. Marshall Watts for having called attention to a point of some interest with regard to the spectra of comets, viz., which of the carbon spectra agrees with the cometary spectrum? In the case of Brorsen's comet the most important question was, whether the spectrum differed *largely* from that of other comets, as found by Dr. Huggins in 1868, and not having much leisure at the time of writing to examine the question of the different spectra of carbon, I overlooked the circumstance that the comparison spectrum used by Prof. Young was the first or flame spectrum of carbon. The difference, however, in the positions of the bands in the two spectra of carbon is a quantity which it is not very easy to answer for in the case of a faint cometary spectrum, and it is but a small fraction (less than one-fourth) of the discordance between Dr. Huggins's measures in 1868 and those made at the present return of the comet.

In the comparisons made at Greenwich the induction-spark (without Leyden jars) was taken in a vacuum-tube containing alcohol vapour at a pressure of 1·2 mm., and the green comet-band was compared with this spectrum exactly in the manner described by Dr. Watts, though practical difficulties of manipulation prevented our making comparisons with the flame spectrum, as I wished. In fact the awkward position of the spectroscope in observing the comet below the pole made the observations extremely difficult, and caused great loss of time, so that the results are not so numerous as they would otherwise have been. On April 17 I used a micrometer eye-piece, with a movable bar, the breadth of which corresponded to 30 tenth-metres, whilst the slit was of such a width that the line with which the band in the alcohol-spectrum commences was 45 tenth-metres broad. The bar was brought up from the blue end so as just not to hide the less refrangible edge of the comet-band; the spectrum from the alcohol vacuum-tube was then flashed in, and the less refrangible edge of the carbon-band was found to be just visible beyond the bar. Several comparisons were made in this way, and I estimated that the uncertainty in the determination of the coincidence between the less refrangible edges of the comet and carbon-bands was but a small fraction of the breadth of the bar (30 tenth-metres). I did not obtain any micrometer readings. On April 19 and 28 Mr. Maunder, from readings with a bright-line micrometer, found for the position of the bright edge of the comet-band in the green, compared with the centre of the line at the edge of the alcohol-band (wave-length, 5198·3):—

	Comet-band. Tenth-metres.	Wave-length inferred.	Width of Slit.
April 19	... 0·5 to blue ...	5190 ...	0·009 in. = 16 tenth-metres.
28	... 4·5 to red ...	5191 ...	0·013 ,, = 24 ,,

In computing the wave-length of the bright edge of the comet-band, half the breadth of the alcohol-line (= width of slit) has been applied. In a similar manner the wave-length of the bright edge of the comet-band in the yellow was found to be 2·4 tenth-metres to the red of the edge of the alcohol-band at 5610·5, or at 5580, allowing for the width of the slit, which was 0·033 in. or 65 tenth-metres. The position of the blue band was estimated to be *approximately* coincident with the blue band of alcohol at 4834, but this determination is very rough indeed. The dispersion used was that of one "half-prism," viz., 20° from A to H, equivalent to four flint prisms of 60° with a magnifying power of twelve. In my former letter I, by mistake, gave the dispersion as equivalent to two prisms only, instead of four. The high dispersion used is of course an important element in estimating the accuracy of the determination, and on comparing afterwards the flame and vacuum-tube spectra of carbon with the width of slit and other conditions of observation the same as on April 17 and 19, I found the two bands so widely separated that it appeared impossible to mistake one for the other in estimating a coincidence. I may add that the spectrum of Coggia's comet also was found to be identical with the second spectrum of carbon. With regard to Dr. Huggins's observations of Comet II. 1868, and Coggia's comet, Dr. Watts does not give his reasons for the assertion that the comparison spectrum was the first spectrum of carbon. According to the diagram given by Dr. Huggins, the spectrum in olefiant gas is distinctly different from that in olive oil, which I presume is the first spectrum, and the comet-spectrum agrees with the former. As far as I can judge, this is the spectrum which we have obtained in vacuum-tubes, whether they contain alcohol, carbon-oxide, carbon-dioxide, or olefiant gas. I do not wish to enter on the question as to whether the differences in the carbon-spectra result from differences of chemical composition or of molecular condition depending on temperature, though I may remark that the same vacuum-tube gives quite a different spectrum when Leyden jars are introduced into the circuit.

W. H. M. CHRISTIE

Royal Observatory, Greenwich, May 17

End-on Tubes, brought to Bear upon the Carbon and Carbo-Hydrogen Question

IN NATURE, vol. xx. p. 28, there is an important paper by Dr. Marshall Watts, touching certain recent observations of carbon spectra so-called, which seems to offer an excellent opportunity for clearing up certain long-disputed points in spectroscopy, and to the satisfaction, I hope, of every one.

Firstly, the Doctor alludes to the recent happy case of Prof. Young, of Princeton, U.S., having last month compared the green band of Brorsen's comet with the green band of a Bunsen gas burner, and found them identical in spectrum place, thereby

bringing the said Brorsen's comet into line with most other comets, as to possessing both that band and material.

Secondly, Dr. Watts alludes to Mr. Christie, of the Royal Observatory, Greenwich, having also recently observed the spectrum of the same comet, and stated that he had thereby found the *same* result as Prof. Young. But the Doctor implies there must be some mistake therein, because—what Mr. Christie compared the sharp edge of the comet's green band, with, and found it coincident, was not the Bunsen gas burner's green band, but that of an alcohol vacuum tube illumined by electric spark; and this latter green band, he says, is in an absolutely different spectrum-place to that occupied by the coal-gas burner's green band.

The first answer here, is both pleasant and simple. I know perfectly well what it is the Doctor alludes to, as being visible in the alcohol vacuum tube, but would beg to remind an accomplished laboratory worker that it is so close in spectral place to the coal-gas flame's green band, that in any spectroscope of very small dispersion, and when the subject is seen only faintly and at intervals in a difficult astronomical observation, such minute difference of place might well be disregarded in comparison with the enormous difference or anomaly of an older, almost historic, record, whose large discrepance, eight times larger than the other difference, was really the thing which both Mr. Christie and Prof. Young had before them, either to prove or disprove. And as they have now each of them independently assured us, by special observations at the end of a telescope in the cold night air, that the enormous anomaly suspected of old no longer exists—they both deserve our best thanks.

But next comes, for those who work in-doors with brighter lights and more powerful spectroscopes, the second part of the answer, with a proof that Mr. Christie, after all, may not have used a differently placed reference to Prof. Young's, even in the least degree, because, *besides* what Dr. Marshall Watts says very truly, there is in the spectrum of an alcohol vacuum tube electrically illumined, there is *also* a something else which he either has not seen, or has not yet recognised as such, but which is the very identical green band of the coal-gas flame in open air.

The special green band which the Doctor *has* seen and recognised in an alcohol vacuum tube is to be seen equally in vacuum tubes of all gases containing carbon in any combination, and is therefore abundantly visible in tubes of carbon monoxide, carbon dioxide, and cyanogen. This, too, is the spectrum which he calls the "Carbon spectrum No. 2," but which I call simply the spectrum of carbon; a spectrum which no one has yet found in any common candle flame, coal-gas flame, or comet in the sky; and it requires apparently the ecstatic heating of the electric spark for its smallest development.

But the other green band, which I shall presently prove is also in an alcohol vacuum tube, though the Doctor may not have recognised it there, he has seen abundantly elsewhere, for it is found in the blue base of every candle, lamp, or coal-gas flame, and he has given the spectrum place of the beginning of it with exceeding accuracy. In fact, the only unhappy thing is, that he will look upon it as pure carbon, calling it the "Carbon spectrum No. 1," when it is so evidently the compound "carbo-hydrogen;" for with my new end-on tubes, while I do *not* see *this* green band in vacua of either carbo-oxygen or carbo-nitrogen (unless ultra-faintly as a trace of impurity), I do see it, and most brilliantly, in tubes of such rich carbo-hydrogens as alcohol and olefiant gas.

Now it is not a little singular as a coincidence merely, that I was actually engaged only yesterday, after an interval of several years, in pointing out to my friend Prof. Swan, of St. Andrews, the existence of "his" carbo-hydrogen blow-pipe flame's lines of its green band, projected upon, and differently placed from, the true elemental carbon green band ot an alcohol vacuum tube, electrically illumined; and we proceeded thus to test the identity of what I called "his" flame lines, by a close proof of place, which is everything in spectroscopy.

A coal-gas and air blow-pipe flame, end-on, was set up before the spectroscope on one side of the table, and on the other side an alcohol vacuum tube, illuminated by 1-inch sparks from a small coil, and viewed also end-on. The spectroscope could be rotated easily in azimuth by endless screw motion, so as to look with its gathering telescope first into the tube, then into the flame, and then again into the tube. The prism train had the large dispersion of 33° between A and H, the telescope a magnifying power of 10, and its pointer was one of Mr. Hilger's latest and most refined steel wedges of almost infinite sharpness.

The slit was made exceedingly narrow, the definition in the centre of the field was super-excellent, and then Prof. Swan micrometrically bisected a certain thin but exceedingly bright line, which looked like an anomaly on the surface, and far within the least refracted edge of the elemental carbon green band of the alcohol tube, and clamped the pointer in that exact spectrum place.

I then rotated the whole instrument round to the blow-pipe flame, and asked him "What is the pointer on now?"

"On the first and brightest line of the blow-pipe flame's green band," he answered, "Alexander Herschel's green giant of carbo-hydrogen, and it is admirably bisected too."

We next rotated back to the alcohol tube, and found the pointer still accurately bisecting that bright line present there, which was a total anomaly in a pure carbon spectrum, though perfectly agreeable to what Prof. Swan wrote of the compound carbo-hydrogen's flame spectrum, twenty-three years ago. Most opportunely present also in that tube, for it enabled Mr. Christie to compare Brorsen's comet with the same identical reference as that used by Prof. Young, though employing an alcohol spark spectrum, and not a gas-burner.

The second line of the blow-pipe flame's green band, though much fainter, is also distinctly seen in the end-on view of the alcohol tube's spectrum, and answers perfectly to a similar test for place as the first line. Wherefore, I would beg to ask, how can I hold any other view than that carbon, as a pure chemical element, and the most refractory that is known, has no spectrum short of electric spark temperature; and what it then shows is, to exact measurement with large dispersion, a perfectly different spectrum to that of the compound gas, carbo-hydrogen; which compound gas, while still existing to some extent in the electric spark tubes, begins its spectral manifestations in the very moderate temperature of merely a farthing tallow candle: a matter to be duly considered in studying the physical condition of comets, which do not show any spectrum (or, for small and "uncondensed" sparks, we may say *the* spectrum) of pure elemental carbon. PIAZZI SMYTH

Edinburgh, May 9

The Victoria University

IN the article on the Victoria University in the last number of NATURE, I observe some inaccurate statements regarding the Queen's University in Ireland.

In the first place there are not *four* colleges, but *three*. Next there are no *degree* examinations in any college, but all are conducted in Dublin by the examiners of the university, who, for the most part, are also professors in the colleges; but there are some examiners who are not professors, and also some professors who are not examiners. A. J. C. ALLEN

Peterhouse, Cambridge

Maps of Old Geological Coast-lines, &c., &c.

I NOTICE in Woodward's "Manual of the Mollusca," when speaking of the "Boundaries of Natural History Provinces," p. 352, the following:—

"The seas are divided by continents and influenced by the physical character of coast-lines, by climates, and currents."

May not the occurrence of different species in different parts of contemporaneous strata help to determine the positions of land and water, &c., in past geological ages? W. W.

Cambridge

[In reply to "W. W.'s" interrogatory, "May not the occurrence of different species in different parts of contemporaneous strata help to determine the positions of land and water, &c., in past geological ages?" we would say, Yes, most certainly; and it is not only by recording the occurrence of *different species*, probably peculiar to different zones of depth, that geologists have long tried to mark out old sea-beds, but more especially by tracing carefully *the occurrence* of the *same species* along extended lines of formations, they have attempted to map out old geological coast-lines. Much has been done in this direction by Godwin-Austen, Forbes, Quenstedt, Oppel, Waagen, Hebert, Oswald Heer, and many others; but much more remains to be accomplished, and "W. W." cannot do better than take up some such line of inquiry for his summer vacations. How much good field-work might be done in three months' holidays in, say, three successive years, with a knapsack on one's back and a hammer in one's hand, let the admirable papers by Dr. Chas. Barrois of Lille tell!—H. W.]

Note on the Iodobromite of A. v. Lasaulx

In the *Jahresberichte für Mineralogie* for 1878 A. v. Lasaulx has described a new silver haloid mineral, having the composition Ag_2Br_2, Ag_2Cl_2, AgI, or $Ag_5Cl_2Br_2I$, which he cites as the first instance of the three haloids occurring crystallised together in nature. Several chloro-bromides of silver have been found in Chili in the silver mines of Chañarcillo, and, according to Dana, an iodobromide has also been detected. The present mineral, which should be called *chlorobromiodide*, was found associated with beaudantite in a mine in the district of Ems, Nassau, in the form of small yellow or olive green octohedrons never exceeding 3 mm. in size. The crystals are very malleable, and can be pressed flat with the blade of a knife, and they possess a good deal of lustre. On analysis they were found to contain :—

Silver	59·96
Iodine	15·05
Bromine	17·30
Chlorine	7·09
	99·40

In 1876 I prepared some of this substance artificially by fusing together the chloride, iodide, and bromide in the proportions of AgI 26·1692, AgBr 41·8708, AgCl 31·9600, which gives an ultimate composition of :—

Silver	60·1336
Iodine	14·1435
Bromine	17·8176
Chlorine	7·9053
	100·0000

The substance was prepared with other chlorobromiodides of silver in order to see the extent to which iodide of silver (which contracts considerably when heated from 142° to 145·5° C.) modifies the coefficient of expansion of the chloride and bromide, which do not present similar anomalies. The results obtained are given in the *Proc.* of the Royal Society, vol. xxv. p. 294, 1877, "On the Effects of Heat on some Chlorobromiodides of Silver," and they are of additional interest now that the substance has been found in nature.

The compound artificially prepared is a brittle yellowish-brown solid, giving a bright primrose-yellow powder, which turns green on exposure to light. (It is noticeable that some of the crystals found by Lasaulx were yellow, others green.) It is a crystalline solid which emits loud harsh noises while cooling from the molten condition. The fusing point is 330° C. The sp. gr. 6·152 when cooled quickly, but when fused and allowed to cool slowly in hot paraffine, the sp. gr. fell to 6·066. A. v. Lasaulx makes the sp. gr. of the mineral as low as 5·713. The artificially prepared compound was found to possess a coefficient of cubical expansion for 1° C. = 0·00012216 between 0° C. and 125·5. Between 125·5 and 131·5 it underwent slight contraction, while between 131·5 and the fusing point the coefficient was 0·0001 5882. It possesses two points of similar density, the one at 131·5° C., the other at or about 123° C. The volumes calculated from the coefficients, taking volume at 0° C. as unity, were found to be :—

Volume at	0° C.	= 1·000000
„	125·5°	= 1·015331
„	131·5°	= 1·015037
„	330°	= 1·046666 (solid)
„	330°	= 1·104050 (liquid)
„	750°	= 1·177979

It is presumable that the other artificially-prepared chlorobromiodides described in the paper cited above will also be found in silver mines.

G. F. Rodwell

Inherited Memory

Having had my attention called, of late, to the subject of the migration of birds, I have of course been interested in the discussion between Dr. Weismann and Prof. Newton, and I cannot help fancying that I have hit on the "missing link" which connects the theory of the former with the facts of the latter.

Are there not scientific men (and is not Dr. Carpenter one of them) who consider that when we say an event has made "such an impression on us that we shall never forget it"—we are not merely using a metaphor, but stating a fact? Now if something analogous to "making an impression" on the brain really takes place whenever we commit anything to memory—is it not possible that if the impression be deeply fixed, the impressed brain may be transmitted by the parent to the offspring, who thus "inherits" its ancestor's memory?

When we remember that birds take the same journey year after year, generation after generation, century after century, nay, even for ages after ages, I think we shall feel that there are more marvellous things in nature than what I am asking you to consider, namely, the possibility that the young bird at last inherits a knowledge of the way, and is capable of performing the journey alone.

If "inherited memory" be accepted as a fact, what a flood of light is thrown on many puzzles which have hitherto been classed as "instincts"; such as the building of birds' nests; the pointing of pointer puppies, the knowledge possessed by young animals of right and wrong food, and of friends and enemies; I am not sure that it will not even throw light on some mysteries in human nature. When I was a child I had a dread of wolves (a very common thing with children), and I find the dread reproduced in one of my own children. Yet wolves have been so long extinct in England that we should probably have to go back many generations before we met with the nurses who quieted crying children by threatening to give them to the wolves. May not this be a case of "inherited memory?"

A. B.

Intellect in Brutes

Some years ago the late Hon. Marmaduke Maxwell, of Terregles, took me to his stable to show me a cat which was at the time bringing up a family of young rats. The cat some weeks previously had a litter of five kittens, three were taken away and destroyed shortly after their birth; next day it was found that the cat had replaced her lost kittens by *three* young rats which she nursed with the two remaining kittens; a few days afterwards the two kittens were taken away, and the cat very shortly replaced them by *two* more young rats, and at the time I saw them, the young rats—which were confined in an empty stall—were running about quite briskly, and about one-third grown. The cat happened to be out when we went into the stable, but came in before we left; she immediately jumped over the board into the stall, and lay down; her strange foster-family at once ran under her and commenced sucking. What renders the circumstance more extraordinary is, that the cat was kept in the stable as a particularly good ratter.

Cargen, Dumfries, May 9 P. Dudgeon

Phosphorescence

In regard to the effect of heat on phosphorescence, your correspondent in last week's number will find that almost similar phenomena have been observed by Dr. Draper, who treats of the whole subject very fully and satisfactorily in his "Scientific Memoirs."

G. S. Thomson

Clifton, May 18

AN INDUCTION-CURRENTS BALANCE[1]

Immediately upon the announcement of Arago's discovery of the influence of rotating plates of metal upon a magnetic needle (1824), and Faraday's important discovery of voltaic and magneto-induction (1831), it became evident that the induced currents, circulating in a metallic mass, might be so acted upon either by voltaic or induced currents as to bring some new light to bear on the molecular construction of metallic bodies.

The question was particularly studied by Babbage, Sir John Herschel, and by M. Dové,[2] who constructed an induction balance, wherein two separate induction coils, each having its primary and secondary coils, were joined together in such a manner that the induced current in one coil was made to neutralise the induced current in the opposite coil, thus forming an induction balance, to which he gave the name of differential inductor. In those days physicists did not possess the exquisitely sensitive galvanometers and other means of research that we possess to-day, but sufficiently important results were

[1] "On an Induction-Currents Balance, and Experimental Researches made therewith." By Prof. D. E. Hughes. Read at the Royal Society, May 15.

[2] De la Rive, "Treatise on Electricity," vol. i. chap. v. (London, 1853)

obtained to prove that a vast field of research would be opened if a perfect induction balance could be found, together with a means of correctly estimating the results obtained. In experimenting with the microphone I had ample occasion to appreciate the exquisite sensitiveness of the telephone to minute induced currents. This led me to study the question of induction by aid of the telephone and microphone. The results of those researches have been already published.[1]

Continuing this line of inquiry, I thought I might again attempt to investigate the molecular construction of metals and alloys, and with this object I have obtained, after numerous comparative failures, a perfect induction balance which is not only exquisitely sensitive and exact, but allows us to obtain direct comparative measures of the force or disturbances produced by the introduction of any metal or conductor.

The instrument which I have the honour to present to the Royal Society this evening, consists (1) of the new induction-currents balance; (2) microphone, with a clock as a source of sound; (3) electric sonometer, or absolute sound measurer, a late invention of my own; (4) a receiving telephone and three elements of Daniells' battery.

In order to have a perfect induction-currents balance suitable for physical research, all its coils, as well as the size and amount of wire, should be equal. The primary and secondary coils should be separate, and not superposed. The exterior diameter of the coils presented this evening is 5½ centims., having an interior vacant circular space of 3½ centims., the depth of this flat coil or spool is 7 millims.

Upon this box-wood spool are wound 100 metres of No. 32 silk-covered copper wire. I use four of such coils, formed into two pairs, the secondary coil being fixed permanently, or by means of an adjustable slide, at a distance of 5 millims. from its primary; on the second similar pair there is a fine micrometer screw, allowing me to adjust the balance to the degree of perfection required.

These two pair of coils should be placed at a distance not less than 1 metre from each other, so that no disturbing cause should exist from their proximity.

The two primary coils are joined in series to the battery, the circuit also passing through the microphone.

In place of the telephone I have sometimes used a magnetic pendulum, the swing or the arc described indicating and measuring the forces.[2] I am at present engaged upon a very sensitive voltameter, which shall indicate and measure the force of rapid induced currents. The telephone, however, is well adapted as an indicator, but not as a measurer of the forces brought into action. For this reason I have joined to this instrument an instrument to which I have given the name of electric sonometer. This consists of three coils similar to those already described, two of which are placed horizontally at a fixed distance of 40 centims. apart, and the communication with the battery is so arranged that there are similar but opposing poles in each coil; between these there is a coil which can be moved on a marked sliding scale divided into millimetres; in a line with these two opposing primary coils, the centre coil is the secondary one, and connected by means of a circuit changing key with the telephone in place of the induction-balance. If this secondary coil is near either primary coil we hear loud tones, due to its proximity. The same effect takes place if the secondary coil is near the opposing coil, except that the induced current is now in a contrary direction, as a similar pole of the primary acts now on the opposite side of the induction-coil; the consequence is that as we withdraw it from one coil approaching the other, we must pass a line of absolute zero, where no current whatever can be induced, owing to the absolute equal forces acting equally on both sides of the induction-coil. This point is in the exact centre between the two coils, no matter how near or distant they may be. We thus possess a sonometer having an absolute zero of sound; each degree that it is moved is accompanied by its relative degree of increase; and this measure may be expressed in the degrees of the millimetres passed through, or by the square of the distances in accordance with the curve of electro-magnetic action.

If we place in the coils of the induction-balance a piece of metal, say copper, bismuth, or iron, we at once produce a disturbance of the balance, and it will give out sounds more or less intense on the telephone according to the mass, or if of similar sizes, according to the molecular structure of the metal. The volume and intensity of sound is invariably the same for a similar metal. If by means of the switching-key the telephone is instantly transferred to the sonometer, and if its coil be at zero, we should hear sounds when the key is up or in connection with the induction-balance, and no sounds or silence when the key is down or in connection with the sonometer. If the sonometer-coil was moved through several degrees, or through more than the required amount, we should find that the sounds increase when the key is depressed; but when the coil is moved to a degree where there is absolute equality, if the key is up or down, then the degree on scale should give the true value of the disturbance produced in the induction-balance; and this is so exact that if we put, say, a silver coin whose value is 115°, no other degree will produce equality. Once knowing, therefore, the value of any metal or alloy, it is not necessary to know in advance what the metal is, for if its equality is 115°, it is silver coin; if 52, iron; if 40, lead; if 10, bismuth; and as there is a very wide limit between each metal, the reading of the value of each is very rapid, a few seconds sufficing to give the exact sound-value of any metal or alloy.

During the course of these experiments with this instrument I noticed that my own hearing powers varied very much with state of health, weather, &c., that different individuals had wide differences of hearing, and that nearly in all cases one ear was more sensitive than the other; thus whilst my degree of hearing was 10°, another might be 60 in one ear and 15 in the other.[1]

Dr. Richardson, F.R.S., who upon my invitation investigated this subject, became so impressed with the value of the instrument as an absolute measurer of our hearing powers, and its capabilities of throwing much light upon its relation with health, that he has undertaken a series of researches which will extend over some time, and which I think, from some facts already gained, will be of great value to the medical profession. These experiments are now in his very able hands, and he will in due time announce the results to the Royal Society.

If an observer's hearing is limited to 10°, how can we hear results below this line? I should have stated that when used to measure the hearing power, we determine on a constant standard of force such as one element Daniell, but if we increase the number of elements we in the same ratio increase the inductive disturbance, and thus by a large increase of force bring within our range results too feeble to be heard without its aid, the sonometer constantly, however, giving the same degree for equality as the increased force is also used on this instrument. Thus in our measurements we can entirely neglect the amount of battery, as its comparative results remain a constant.

As a rule three Daniell elements will be found quite sufficient, and even this weak force is so exquisitely sensitive that it will find out the smallest fraction of difference in weight or structure of metals. Thus two silver coins such as a shilling, both quite new, and both apparently of the same weight, will be found to possess a

[1] *Comptes Rendus*, December 30, 1878, and January 20, 1879; Society of Telegraph Engineers, March 12, 1879.
[2] *Telegraphic Journal*, December 15, 1878.

[1] To this portion of my instrument when used as a measurer of our hearing powers, we have given the name of audiometer.

difference of weight which the instrument at once indicates.

The following experiments will show its exceeding sensitiveness and its wide field of usefulness as an instrument of research.

1. If we introduce into one pair of the induction coils any conducting body, such as silver, copper, iron, &c., there are set up in these bodies electric currents which react both upon the primary and secondary coils, producing extra currents whose force will be proportional to the mass, and to its specific conducting powers. A milligramme of copper on a fine iron wire, finer than the human hair, can be loudly heard and appreciated by direct measurement, and its exact value ascertained. We can thus weigh to an almost infinitesimal degree the mass of the metal under examination; for instance, if we take two English shilling pieces fresh from the Mint, and if they are absolutely identical in form, weight, and material, they will be completely balanced by placing one each in the two separate coils, provided that for these experiments there is an adjustable resting-place in each pair of coils, so that each coil may lie exactly in the centre of the vacant space between the primary and secondary coils. If, however, these shillings are in the slightest degree worn, or have a different temperature, we at once perceive this difference, and if desired, measure it by the sonometer, or, by lifting the supposed heaviest coin at a slight distance from the fixed centre line, the amount of degrees that the heaviest coin is withdrawn will show its relative mass or weight as compared with the lightest. I have thus been able to appreciate the difference caused by simply rubbing the shilling between the fingers, or the difference of temperature by simply breathing near the coils, and in order to reduce this sensibility within reasonable limits, I have only used in the following experiments 100 metres of copper wire to each coil and three cells of battery.

2. The comparative disturbing value of discs of different metals, all of the same size and form of an English shilling, and measured in millimetre degrees, by the sonometer, is the following:—

Silver (chemically pure) ...	125	Iron (chemically pure) ...	45
Gold ,, ,, ...	117	Copper (antimony alloy)	40
Silver (coin)	115	Lead	38
Aluminium	112	Antimony	35
Copper	100	Mercury	30
Zinc	80	Sulphur (iron alloy) ...	20
Bronze	76	Bismuth	10
Tin	74	Zinc (antimony alloy) ...	6
Iron (ordinary)	52	Spongy gold (pure) ...	3
German silver	50	Carbon (gas)	2

These numbers do not agree entirely with any lists of electrical conductivity I have yet met with; the numbers are, however, invariably given by the sonometer, and the divergence may be due to some peculiarity of structure of the metals when formed into disks. Future investigations with this instrument will, no doubt, give more correct values than I have been able to obtain with my limited means of research.

3. It will be seen from the above that the instrument gives very different values for different metals or alloys; consequently, we cannot obtain a balance by employing two disks of different metals, and the instrument is so sensitive to any variation in mass or matter that it instantly detects the difference by clear loud tones on the telephone. If I place two gold sovereigns of equal weight and value, one in each coil, there is complete silence, indicating identity or equality between them. But if one of them is a false sovereign, or even gold of a different alloy, the fact is instantly detected by the electrical balance being disturbed. The instrument thus becomes a rapid and perfect coin detector, and can test any alloy, giving instantly its electrical value. The exceeding sensitiveness of this electrical test I shall demonstrate by experiment this evening. Again, as regards coins, it resolves an almost magical problem. Thus, if a person puts one or several coins into one pair of coils, the amount or nominal value being unknown to myself, I have only to introduce into the opposite coils, different coins successively, as I should weights in a scale, and when perfect balance is announced by the silence, the amount in one box will not only be the same nominal value, but of the same kind of coin.

4. We find by direct experiment with this instrument that the preceding results are due to electric currents, induced by the primary coil, and that it is by the reaction of these that the balance is destroyed, for, if we take an insulated spiral disk or helix of copper wire, with its terminal wires open, there is no disturbance of the balance whatever, notwithstanding that we have introduced a comparatively large amount of copper wire; but on closing the circuit the balance is at once very powerfully disturbed.

If the spiral is a flat one, resembling a disk of metal, and circuit closed, we find that loud tones result when the spiral is placed flat, or when its wire is parallel to those on coils; but if it is held at right angles to these wires no sound whatever is heard, and the balance remains perfect. The same thing occurs with disks of all non-magnetic metals, and a disk of metal placed perpendicular to the coils exerts no influence whatever. The contrary result takes place with a spiral of iron wire or disk of iron, the induced current circulating in the spiral is at its maximum when the spiral lies flat or parallel with the coils, giving no induced current whatever when at right angles, but the disturbances of the induction-balance is more than four-fold when perpendicular to the wires of the coils, than when parallel with the same. That this result is simply due to the property of magnetic bodies of conduction of magnetism, we shall see in some following experiments.

That the currents in non-magnetic metals travel in a circle corresponding to that of the primary coil, may be seen with spongy gold. In its first extremely divided state it falls below our zero of hearing, on slightly shaking the bottle we have 2° as its value; on pressing it its value rapidly increases with the pressure, until when formed into a solid disk its value becomes 117°.

5. The instrument proves that a very remarkable difference exists in bars of iron of the same exact form and size, but of different provenance or treated in a different manner; in point of fact, no two bars, cut off of the same rod, and treated alike, are exactly of the same value, or induce a complete balance.

Mr. Stroh, the eminent instrument-maker, has kindly furnished me with numerous samples, varying in value in degrees of the sonometer from 100 to 160.

Chemically pure iron was found to be the best, but still very slightly superior to ordinary iron, which had been drawn into a wire of the required thickness. The fibrous condition thus developed being highly favourable (if softened by heat) for the conduction of magnetism. From numerous examples I select a few indicative values:—

	Softened.	Tempered.
Chemically pure iron	160	130
Forged soft iron	150	125
Wire-drawn iron	156	120
Cast steel	120	100

6. As yet the instrument has given no indications of molecular change produced by magnetism in non-magnetic bodies, but the great change which takes place in all magnetic bodies, except hard-tempered cast steel, indicates that a molecular change of structure, analogous to that of tempering, takes place upon iron, steel, and nickel.

If we place a disk of iron in one of the coils, we find that the balance is destroyed, and that the iron has weakened the induction by the absorption of work done in inducing

the circular currents. This can be perfectly balanced by placing a small coin or disk of silver or copper in opposite coils; but if an iron wire or rod is placed perpendicular to the coils, then increase of inductive force takes place in those coils by the conduction of induced magnetism from primary to secondary, and the iron can no longer be balanced by silver, copper, or any non-magnetic metal. The coils must be either removed farther apart, so as to reduce the increased force, or balanced by an equivalent amount of iron or magnetic conduction in opposite coils.

An interesting case of both reduction and increase of force in the same pair of coils occurs if we place a disk of iron, not in the centre of coils, but in the vacant space between the coils. We thus reduce the force by 150°. If, in addition to this, we place iron wires perpendicular and in the centre, there is increase of force, and if this increase is so proportioned as to be 150°, we immediately restore the balance, and we have here in the same coil two separate pieces of iron, each disturbing the balance and giving out loud tones, but producing no effect whatever, when both are introduced at the same time, complete silence being the result.

7. These coils prove what has already been long known, viz., that hard steel has a far less conducting power for magnetism than soft iron, although the hard steel has a far higher retaining power. This instrument demonstrates a point, which I have not yet seen remarked, that magnetism does not in itself change the conducting powers, but that it produces a molecular change of structure in iron, analogous to that of tempering; for if we balance two soft iron rods against each other, the balance being made perfect by the addition of fine iron wires on the weakest side, we find that on strongly magnetising this bar, by drawing it across a strong compound magnet, and on replacing it in its coil, it has lost 30 per cent. of its conducting power; or if, instead of magnetising we make this iron red hot and plunge it in cold water, the loss of conducting power will be very similar—25° to 30°. If these experiments are repeated upon various degrees of iron approaching steel in character, we find that as it already possesses hardness or temper, it is less and less affected by magnetism, until we arrive at hard cast steel, where magnetism no longer produces any change in its conducting powers. From this I draw the conclusion that the effect of magnetism is very similar to that of temper, and shall show under the effects of strain and torsion that magnetism produces this temper or strain perpendicular to the lines of magnetic force.

8. The instrument shows that a remarkable change takes place in the magnetic conducting power of iron and steel on subjecting the wire under examination to a longitudinal strain; for if we pass an iron wire through the centre of both coils, half a millimetre diameter and 20 centimetres or more in length, so arranged by a winding key that we can apply a strain to this wire, we find a magnetic conducting value, unstrained, of 100, but on applying a slight strain its value rapidly increases, being more than double at its breaking point. If during this strain we strike the wire, we hear its musical tone, and no matter how much we may wind or unwind it, provided we do not pass its limits of elasticity and similar wire is used, that the same musical tone will invariably give the same magnetic value. Thus the note A, or 435 complete vibrations per second, gave always the magnetic value of 160, or 60 per cent. increase of power over the unstrained wire. If whilst this wire is strained, giving the value 160, we magnetise it by drawing over it a strong compound magnet, the note remains the same, showing no difference of tension, but its magnetic value has fallen 80°, being now 80 instead of 160; and this wire can never again be brought by strain up to its previous high conducting powers. Now as we have seen that magnetism produces no change in hard tempered steel, but that it does so in soft iron very analogous to that of temper, and as the effect of strain would be also to harden the fibres by bringing them all parallel to the line of mechanical strain; and as this improves its conducting power, while magnetism instantly destroys all the benefits of the longitudinal mechanical strain, we can only draw the conclusion that magnetism produces a strain analogous to temper, but contrary to that of the longitudinal mechanical strain; in other words, that the magnetic strain is produced perpendicularly to its lines of force.

This view is sustained by the effects of torsion; for if, in place of straining the wire, it is twisted, instead of increasing, it rapidly decreases in magnetic conductive value, each turn or twist decreasing its power of conduction in a remarkable constant line of decrease. At eighty turns of this wire there was a decrease of 65 per cent.; at eighty-five turns the wire broke, and on testing it to see if magnetism had any decreasing effect on it, I found that it produced no change whatever; but this twisted soft iron wire had now remarkable permanent retaining powers of magnetism, being superior to tempered cast steel.

Again, if we take three similar pieces of soft iron wire, leave the first for comparison in its natural condition, strain the second by a longitudinal strain until it is broken, and twist the third by a torsion-key until it also is broken; we find on magnetising equally these three wires, and allowing ten minutes' repose, that the first or untouched wire has a retaining power of magnetism of 100, the second only of 80, and the third, or twisted wire, of 300. I hope by the light thus given soon to be able to produce a magnet whose force shall be greatly in excess of what we have hitherto possessed, our difficulty at present being that in order to temper steel we must heat it to redness, and this allows the molecules to rearrange themselves contrary to the object we have in view.

9. There is a marked difference of the rapidity of action between all metals, silver having an intense rapidity of action. The induced currents from hard steel or from iron strongly magnetised are much more rapid than those from pure soft iron; the tones are at once recognised, the iron giving out a dull, heavy, smothered tone, whilst hard steel has tones exceedingly sharp. If we desire to balance iron we can only balance it by a solid mass equal to the iron to be balanced. No amount of fine wires of iron can balance this mass, as the time of discharge of these wires is much quicker than that of a larger mass of iron. Hard steel, however, can be easily balanced, not only by steel but by fine iron wires, and the degree of the fineness of these wires required to produce a balance gives a very fair estimate of the proportionate time of discharge. The rapidity of discharge has no direct relation with its electrical conductivity, for copper is much slower than zinc, and they are both superior to iron.

10. The instrument shows a marked difference in all metals, if subjected to different temperatures. The value is reduced in non-magnetic metals, and this we should expect from the known influence of temperature on the electrical conductivity; but in the case of iron, steel, and nickel (as it has already been remarked by many), the contrary takes place, namely, a far higher degree of magnetic conductivity. A bar of soft iron, whose value at the temperature of the room, 20° C., was 160, became on heating it to 200° C., 300, that is to say, its value was nearly doubled. A bar of pure nickel, whose value at 20° was 150, became on heating it to 200°, 320; thus, in the case of nickel, its value for magnetic conductivity was more than doubled, and at this heat it surpassed the chemically pure iron at the same heat, giving a magnetic value of 320 against 300 for the iron, but at the normal temperature of 20° the iron had more magnetic power of conduction than nickel. Heating nickel by simply plunging it into boiling water increased its force from 150

to 250, plunging this same bar into ordinary cold water reduced its value to 130; thus the mere difference of the normal temperature of the air in the room and water which had been in this room some hours produced 20° of difference. In fact, I found that the radiant heat from the hand would raise the magnetic value several degrees, and thus nickel may be regarded as a magnetic thermometer far more sensitive than the ordinary mercurial centigrade.

The instrument also measures the electrical resistance of wires or fluids. In order to make it do this we have only to place the resistance to be measured across the two wires of one induction-coil and on the other known resistance units. In this way we can produce a perfect balance, for it then becomes an induction bridge, the results and modes of testing of which are somewhat similar to Wheatstone's bridge.

It measures also the electrostatic capacity of Leyden jars or condensers, and is sufficiently sensitive to appreciate and measure a surface of tinfoil not larger than four inches square, the condenser being simply placed between the wires of one pair of coils, and the disturbance produced being measured on the sonometer.

I could cite many more interesting experiments in other branches of physical research for which this instrument offers a wide field of observation; but my object this evening is neither to broach new theories nor to correlate at present the results obtained with views already advanced by Ampère and others.

My only desire has been and is to show the wide field of research the instrument opens to physical inquirers. I trust that in more able hands it may serve to elucidate many physical phenomena.

ON THE EVOLUTION OF THE VERTEBRATA[1]

III.

CROCODILIA.—The crocodiles form another group of reptiles which has become isolated from all the contemporary groups or orders. The most perfect antithesis of the bird, the crocodile, is, nevertheless, in essentials, in strict conformity with the bird pattern; or, rather, both it and the bird conform to the pattern of some ideal or vanished reptile.

This likeness can be shown in the body, but it is most evident in the head; although unlike the bird's skull in general specialisation, that of the crocodile is, in all essential respects and in numberless details, like that of a young bird. Compare the strong, solid, and dense skull of the crocodile, with its thick, pitted, and rugose bones, and accurate and dentated sutures, with that of a parrot, a toucan, or a hornbill—scarcely a suture left, the bone looking like polished ivory and the substance so completely spongy within that its weight is but little more than that of a few quills of the same bird. Yet these lightest and most delicate of all skulls had once all the sutures seen in that of the crocodile, and the two types of skull developed each "centre" in the same manner and on a similar model; in the middle of the incubating period they were so much alike that one diagram might have served to illustrate both.

In their covering, as well as in their general form, the crocodiles contrast strongly with the birds; instead of a soft plumage, often gorgeous in colour, they are invested with a coarse armour of segmental rows of rough plates of bone (dermostoses), coated over with horn. Representatives of the turtle's plastron are seen in the so-called abdominal ribs—which must not be confounded with like structures of the same name seen in the chamæleon and *Hatteria*—and in the inter-clavicle, which is fixed to the under-surface of the breast-bone.

The frame-work of the body is well ossified in the adult, and the vertebræ and ribs are very similar to those of a bird, the greatest difference being in the neck, which is much shorter and stouter, and has much larger rudimentary ribs, which remain permanently distinct. In the young of the *Ratitæ* (Emeu, &c.), however, all the cervical vertebræ except the atlas and axis, have a pair of ribs, which remain distinct for a considerable time in the upper part and permanently in the lower part. The crocodile's sacrum also, instead of being composed of a large number of joints, has merely two, that carry the pelvis, whilst the tail, instead of being arrested, as in living birds, is developed, as in the ancient *Archæopteryx*. The vertebræ of the crocodile are for the most part *procœlous* (concave in front and convex behind), and thus resemble those of the dorsal region of plovers, penguins, and some other water-birds. The setting in of the ribs and their overlapping (*uncinate*) processes are also similar to what is seen in birds.

The rhomboidal sternum is cartilaginous, and sends out behind a pair of *xiphoid* processes, being defended in front by the bony interclavicle, which is the counterpart of the leg of the Y-shaped merrythought of the fowl. The shoulder-girdle is composed of a pair of cartilages with a gentle curve and of a moderate width; each is ossified by two bones, an upper, the *scapula*, and a lower, the *coracoid*.

In the head, all distinction between dermal scutes and sub-cutaneous bones is lost; a thick web is ossified throughout, and has only left a thin layer of the skin soft, as a "quick" to the horny coat. From the snout to the exit of the optic nerves, the internal cranium is unossified, while the posterior part is well ossified, as are also the basal region up to the pituitary body, the capsules of the ear, and the alisphenoids. The labyrinth of the nose is very simple. A hard palate is formed by the maxillaires, palatines, and pterygoids, thus causing the nasal passages to open far back in the throat, this specialisation being of advantage to the crocodile while drowning his prey.

The structure of the organ of hearing agrees with that of the tortoises and the higher lizards, the drum cavity being formed inside the quadrate, into which an air-tube (*siphonium*) opens into the mandible, as in birds. The two drum cavities communicate in a passage running over the skull behind. A rudiment of this passage exists in birds, and in the higher kinds opens into the spongy tissue which lies between the two tables of the skull.

Birds.—The lower tentative forms of birds have for the most part evidently come and gone during the time the crocodiles have been in existence. The palæontologists, however, are beginning to show us how thoroughly intermediate between the true reptiles and birds the extinct birds of the chalk and the oolite were. The most ancient or generalised types of living birds, the ostrich tribe, are all incapable of flight, but the oldest bird known in the fossil state—*Archæopteryx*—was well fitted for flight.

Interesting connecting links between the ostrich tribe and the higher forms are seen in the southern world (*Notogæa*), where many of the birds have a much lower and more reptilian structure than their northern relatives, their power of flight being less, their brain smaller, and in many cases they are deficient in the inferior larynx or *syrinx*. Thus the South American *Tinamous*, which are intermediate between the ostrich tribe and the grouse, have a very small brain, and consequently such low intelligence that they have not the sense to use their own wings; moreover, their flesh resembles that of a reptile, they possess lacertilian super-orbital bones, and a considerable number of the sutures in the head remain permanently open. These birds do not so much resemble the South American Rhea as the Australian *Apteryx*, representative species being often found in these two regions which correspond with each other, but are far more ancient than, and do not correspond with, the types found north of "Wallace's Line."

[1] Abstract of Prof. Parker's Hunterian Lectures, delivered at the College of Surgeons, commencing on February 10. Continued from p. 64.

The influence of desert or prairie life has doubtless had much to do with the modifications found in the ostrich tribe; the principal of these modifications are, the abortion of the tail, the lessening of the wing, the huge increase in the size of the hind-limbs, and the suppression of unnecessary toes.

It is quite within the bounds of reasonable conjecture to suppose that from time to time great waves of morphological force, so to speak, and fresh revivals of life, passed over the old reptilian fauna, and that many kinds of the more ductile reptiles yielded to the influence of these waves. When, however, one member improved, the other members improved with it; the loss of digits and their claws, the sport that appeared in the exchange of feathers for scales, the increased solidity of the sacral region, and the tighter setting on of the hind limbs—these were only a few of the things that were correlated in this radical reform of the old reptilian types. The teeth were only slowly lost, as the invaluable papers of Prof. Marsh show. Epidermal imitations of teeth, however, occur in existing ducks and geese, and in the South American Passerine, *Phytotoma rara*, in which latter they are ossified from the jaw.

The hot condition of the bird's blood has much to do with the intensity and rapidity of its early metamorphosis. The time in which arboreal birds (*Altrices*) are ripened for hatching is marvellously short, and after this, in a single month, many of them have learnt their lesson in flying, and begin to be ready to migrate.

The segmented form of the simpler fish, or amphibian, is still to be traced in the bird. The embryo of the swan develops six dozen segments behind the head, twenty-five of which belong to the neck. Most of these segments can be traced in the adult, except those of the tail, the posterior ten of which, though separate at the time of hatching, grow together to form the plough-share bone, on which the tail-quills are set.

The endo-skeleton is greatly developed, and its ossification is carried to the utmost degree of perfection, only traces of cartilage persisting in the joints and often in the nose.

The outer skeleton may be divided into three categories. The first of these consists of the exuberant and unique growths of the epidermis—the feathers and quills, to which must be added the horny sheaths of the beak and the scaly coverings of the legs. The second consists of the overlapping series of cartilages that become ossified to form the limb-girdles from which the limbs grow out, and also a pair of sub-cutaneous cartilages in front of the head, which belong to the labial category, and sometimes there is one on each ramus of the mandible. The third takes in the sub-cutaneous bones that invest the proper endo-skeleton, whether bony or cartilaginous, and the ossified tendons and fasciæ (*aponeuroses*). There are three proper investing bones, as a rule, attached to the shoulder-girdle, which coalesce to form the greater part of the merrythought (*furcula*); these, as before mentioned, are the counterparts of the ventral splint-bones of Plesiosaurus and Hatteria, and their non-coalesced representatives are also seen in lizards and in the Monotremes. In the head there is a large number of investing bones, which, however, enjoy for the most part a very temporary independent existence.

The increased size of the brain-mass has given rise to a very different proportion of cranial to facial elements as compared with what exists in the reptile, and the process of ossification is carried to its utmost perfection. Except at the articular extremities of the bones, all the original cartilage rapidly disappears; this matrix is succeeded by marrow, which is in many cases completely absorbed, giving rise to air-cavities, which open into the nearest air-sac.

The endo-skeletal palatine bones are ossified to a great extent whilst the tissue is still formed of young and soft cells, before the solid hyaline cartilage has had time to grow, and in many passerine birds the exo-skeletal vomers are grafted upon a pair of cartilages, which, however, also belong to the outer skeleton. No true cartilage has yet been found in the outer ear. Rudiments of the hyoid and first branchial arch exist behind the lower jaw.

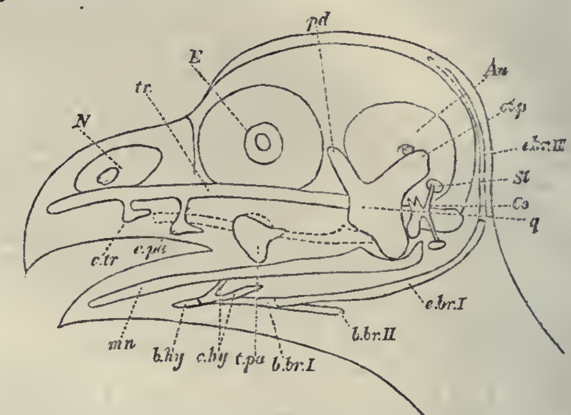

Diagram of the Chondrocranium of a Passerine Bird. *au*, auditory capsule; *b.br*, basi-branchial; *b.hy*, basi-hyal; *c.hy*, cerato-hyal; *c.br*, cerato-branchial; *co*, columella; *c tr*, cornua trabeculæ; E, eye; *e.br*, epi-branchial; *e.pa*, ethmo-palatine; *mn*, mandible; N, nasal capsule; *ot.p*, otic process; *q*, quadrate; *st*, stapes; *t.pa*, trans-palatine; *tr*, trabeculæ

The protrusible and retractile face of the bony fishes is constructed in a manner very similar to that seen in the hinged fore-face of a fowl or parrot; in these birds, as in the fishes, the pre-maxillaries push the maxillaries aside, cover them over, and keep them from the dentary edge, thus converting the bones usually so massive, into feeble "moustache bones" (*ossa mystacea*, Cuvier).

Mammals.—Such a hypothesis as that Nature bred either all her birds or all her mammals from one stock is at once upset by the facts presented by the structure of the lowest mammals—the duck-billed platypus and the echidna. Between the mammals and the types which foreshadow them, viz., the Selachians and the Batrachians, there is unfortunately a large chasm; and moreover, the platypus and echidna refuse to lie fairly in the direction indicated at the top of this chasm, as they confusingly partake of the characters of the reptile and bird; as well as those which are peculiarly mammalian.

The skeletal parts of the mammal are modified in a great number of ways answering to the great variety of their modes of life, and especially in regard to prehension and progression. In the higher kinds there are few or no subcutaneous bones (*parostoses*) in the body, but the head depends upon these for its construction as much as in the birds: where there are no clavicles there are no parastoses behind the head.

In the lowest forms (platypus and echidna) there are three clavicular bones; in the pangolin (one of the *Edentata*) the body is covered with large imbricated scales; the armadillos have strong body armour, which is both bony and horny, as in the tortoises and crocodiles, and in certain rodents, such as the South American *Cœlogenys* and *Lophiomys imhausii*, the bones of the head resemble very much the bony scutes of the lower types, for they become granular and almost ganoid on their outer surface. The endoskeleton and the overlying limb-girdles and limbs are developed to a perfection peculiar to the mammal, the culmination of which is seen in our own species.

Above the lowest forms, neither in the low marsupials nor in the almost equally low Edentata, do we find the middle collar-bone (inter-clavicle). Moreover, in the large Herbivora with a keeled chest, the paired clavicles also disappear; in man, monkeys, bats, moles, and shrews,

they have their largest development, but do not correspond merely to the paired bones of the lizard and platypus, being formed both of cartilage and bone as in the bird. The girdle of the hind-limb is of a more archaic and less metamorphosed pattern than that of the fore-limb; in man the pelvis corresponds very closely with the shoulder-girdle of the frog. The limbs agree nearly with the tailed amphibian pattern. The main modification of the spine is seen in the presence of inter-central pads or buffers of cartilage, and a pair of bony *epiphyses* to each centrum.

The skull is wrought into one strong, compact building, and the short, solid, lower jaw is articulated directly to the head; the *primary* lower jaw stops growing at a very early period of embryonic life, and then loses, by absorption, the Meckelian rod, which is, indeed, all the arch except its upper part; the working mandible is formed from superficial bone and cartilage, the prototypes of which must be sought amongst the lowest fishes. The upper part of the primary mandibular arch, which in the lower types gives rise to the quadrate, is now specialised to form the *malleus*, or the outermost bone of the chain of the middle ear. One principal external bone and sometimes an imperfect rudiment of one or two others appears on the inside of the primary lower jaw in the embryo, but these enjoy a very short separate existence. In the hyoid arch the upper element, or epi-hyal, is divided off to form the *incus*, the middle bone of the middle ear. The *orbiculare* is a further subdivision of the upper element, and the stapes is a part of the auditory capsule segmented off. The cochlea, which, in the Sauropsida, forms only part of a coil, is now perfected into a spiral chamber with several turns. The membrane of the drum lies at the bottom of a long tube, and is there stretched upon a bone which at first is a mere imperfect ring, but which afterwards grows out as the bony *meatus externus*. The *concha auris* is an opercular cartilage of the first cleft, the essential part of which is the *tragus*.

Outside the primary lower jaw, the two halves of which are confluent in front and below, there is a cartilage having the same relations as the *labial* of a shark; in the outside of this cartilage the *dentary* splint bone appears, and gradually converts it into bone, from before backwards. Throughout life part of this cartilage still remains, capping the convex hinge of the lower jaw; it is probable that the cartilaginous plate within the joint (*meniscus*) and the cartilage lining the temporal bone above, to finish the joint, are derived from the same source.

As already mentioned, the forecast of the mammalian type, which is very plain in the cartilaginous fishes, becomes much more plain, definite, and indubitable in the frog and toad. In fact, the building materials are passed from hand to hand, as it were, in this way: the batrachian forefathers brought down all things meet for the work, borrowing and taking cartilages from the Selachians, and bones from the Ganoids, and noiselessly forming them, after due selection, into a new, more compounded, and nobler structure.

The rude ancestors of the tribes that give suck began to build on this higher level, with these more varied or better-shaped blocks and plates; and by the infinite cunning, the effectual working of the morphological force, in due time the consummation was effected of vertebrate form. But the consummation of all, the election and selection, that has been going on since the beginning of the ages, is seen in man, who alone gives meaning to, and reads the meaning of, the whole mystery of organic life.

OUR ASTRONOMICAL COLUMN

THE OBSERVATORY OF MANNHEIM.—We have received from Prof. Valentiner, the successor of Prof. Schönfeld in the direction of the observatory at Mannheim, the third part of the "Astronomical Observations" issued from this establishment. The two former parts, published in 1862 and 1875, contained observations of nebulæ and clusters, but without micrometrical measures of the positions of the components of the latter objects; in the present part the two clusters Nos. 1166 and 4410 of Sir John Herschel's General Catalogue are specially treated upon, and the position of thirty-six stars in the former cluster and seventy-one stars in the latter have been determined by micrometrical reference to a number of stars the places of which have been fixed by meridian observations. In this work a filar-micrometer upon the Steinheil refractor has been employed, and both observations and reductions have been made with every care to secure a high degree of precision. Diagrams of the stars observed in each cluster are appended. It is intended to measure the clusters 1454 and 1119 of the General Catalogue in the same manner. Only by patient and accurate measures of this nature can we hope eventually to learn the internal structure of these systems. Prof. Valentiner has given full details of his observations and reductions, which may be advantageously consulted by any one proposing to enter upon similar work. The Mannheim Observatory not possessing a meridian-circle, he has had recourse to the assistance of other observatories—Berlin, Leyden, and Leipsic—for the accurate determination of the positions of his reference-stars.

TEMPEL'S COMET.—M. Raoul Gautier has circulated an ephemeris of this comet, founded upon a correction of his predicted elements from three observations by Dr. Tempel at Arcetri. The positions for May do not materially differ from those which have appeared in NATURE. The corrected orbit is as follows:—

Perihelion passage 1879 May 7·02 M.T. at Berlin.

	°	′	″	
Longitude of perihelion ...	238	11	30·1	From mean equinox 1879·0
,, ascending node	78	45	37·4	
Inclination	9	46	31·6	
Angle of excentricity	27	35	0·6	
Mean daily motion			593″·18	
Log. semi-axis major			0·517880	

THE MINOR PLANETS.—From the *Berliner Astronomisches Jahrbuch* for 1881, which is just published, it appears that of the 194 small planets discovered up to the end of March last, eighteen have been observed at only one opposition, one of the number being *Medusa*, which, if the elements so far determined can be relied upon, has a shorter period of revolution than any other member of the group, *Flora* coming next. Upwards of 150 pages are devoted to the elements and ephemerides of these bodies for 1879, forming the speciality of this publication, upwards of forty calculators in various parts of Europe and America taking part in this laborious work; seventy-one of the ephemerides are by Dr. Maywald, of Berlin, who has been long similarly occupied. As already stated this portion of the *Berliner Jahrbuch* has been sent out to observers in anticipation of the appearance of the volume. The circulars independently issued by Prof. Tietjen have kept astronomers informed as to elements and positions of the newly-discovered bodies.

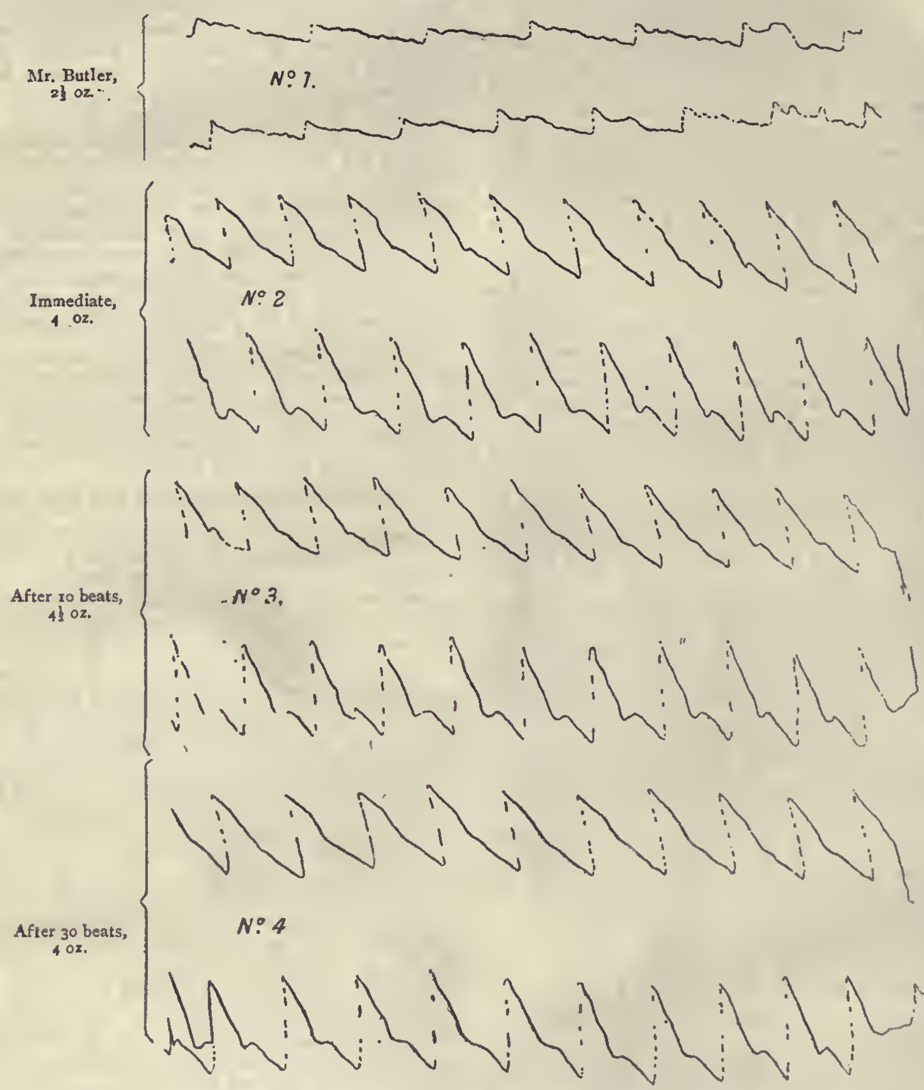
Prof. Peters, of Clinton, New York, announces his detection of a planet which, if new, will be No. 196.

THE OCCULTATION OF VENUS ON AUGUST 20.—On this date Venus, then at her greatest brilliancy, and so of crescent-form, will be occulted by the moon, which is also a narrow crescent at the time. The phenomenon would be one of much interest were it not that it is visible in a dark sky, only in the South Atlantic. If we calculate for the Royal Observatory, Cape of Good Hope, we find that the immersion takes place at 8h. 44m. mean time, but the planet will have set about five minutes previously, and in other parts of the South African Colonies, the occultation is similarly invisible. At St. Helena there will be no occultation.

A SPHYGMOGRAPHIC EXPERIMENT

AN experiment which I have recently been enabled to make by means of the sphygmograph may perhaps be of sufficient interest to deserve a brief record in your columns.

It occurred to me while preparing for the Croonian lectures, which I had the honour of delivering before the College of Physicians a few weeks back, that some light might be thrown on the movement of the blood in the vascular system, if an ordinary tracing of the healthy pulse were compared with one taken under different circumstances, wherein a large portion of the arterio-capillary network was thrown out of the circuit. By the kind assistance of my colleagues, Dr. Sharkey, Mr. Pitts, and Mr. Sandwith, I was able to put this hypothesis to the test, the result being the four pairs of tracings accompanying this communication. The patient in the first case (No. 1) was Mr. Butler, a pupil of the St. Thomas's Hospital, and in the last three instances one of the porters in this institution. The *modus operandi* was very simple. The sphygmograph having been firmly applied to the left



In all the tracings the lower is the normal pulse, the upper one with vessels compressed. Nos. 2, 3, 4, from the same patient, George Watts, æt 37.

radial pulse, a series of tracings was made to ascertain the pressure which produced the most characteristic curve-line. This proved in Mr. Butler's case to be two and a half, in that of the porter, four or four and a half ounces. This adjustment having been obtained, a normal tracing was taken on a broad slip of smoked plate glass at its lower portion. The three gentlemen above-named were instructed to compress simultaneously the two femoral arteries and the right axillary. A second tracing was then taken on the upper half of the same slip, so that it could be accurately compared with that already taken. Mr. Butler's pulse, even after it had been excited by the administration of a full dose of whisky (about three ounces), was too quiet and undemonstrative to give very striking results, though it will be seen that the excursion is diminished, the rate is rendered perceptibly slower in the ratio of six to seven, and the distinctive aortic notch is obscured by a number of smaller undulations. In the case of the porter we had to deal with an older man, of very muscular build, with a strong bounding, though not morbid pulse, who has been for some years in a Guards regiment. The first pair of tracings (No. 2) here showed a very important modification in the contour of the undulation. To eliminate any error due to a

merely transitory change, ten full pulsations were in the second case (No. 3) allowed to elapse after the complete closure of the three large vessels above-named, before the second tracing was taken, and in the third trial (No. 4) thirty beats were steadily counted with the vessels occluded, before the second tracing was obtained. Beyond this I did not feel justified in going, for fear of phlebitic or thrombotic accidents. It will be seen, however, that the change of character in the wave becomes decidedly more marked in each succeeding instance than in that preceding it. It consists roughly in the total obliteration of the dicrotic wave termed the "aortic notch." Accompanying this is an increase of rapidity and suddenness in the line of ascent, which, from being nearly vertical in the uncompressed, bends distinctly backwards in the compressed tracings, thus reproducing the circular arc in which the index of the sphygmograph travels. The latter fact might have been anticipated, but the former is curious, and I believe novel. The compressed tracings might be mistaken by an observer not acquainted with their mode of production, for those of a patient in whom the competency of the aortic valves was gravely impaired, and where the reflux of blood into the ventricle, which, in a healthy condition is prevented by their sudden closure, was freely taking place. On the plausible supposition that the dicrotic wave is a return undulation, a sort of echo sent back from the distal extremity of the arterial tree, it may be suggested that the great shortening thus artificially produced in the wave-length of the fluid undulation causes the primary and dicrotic waves to merge into one another.

I may say that neither of my patients felt any inconvenience from the experiment, either during compression or afterwards. An attempt was made to cut the internal iliacs also out of circuit by compressing the abdominal aorta before its bifurcation; but though to a good anatomist like Mr. Pitts the occlusion of this large vessel was not difficult, it caused so much hiccup and respiratory spasm as to render the continuity of the tracing uncertain.

W. H. STONE

THE ELECTRIC LIGHT

WE have already referred to the Albert Hall Exhibition, and its important bearing on the progress of electric lighting by bringing together the various methods by which it has been proposed to utilise electricity for this purpose. Since then the newspapers have brought us intimations of further progress which it is stated Mr. Edison has made, and as our readers doubtless know, he has taken out one or more patents for various alleged improvements. We have borne, and will continue to bear, willing testimony to the marvellous ingenuity of Mr. Edison in his application of various scientific principles, resulting in inventions that a year or two ago were scarcely dreamt of. We cannot but have the sincerest wish for Mr. Edison's success in whatever he puts his hand to; and his position as an inventor is so high that he needs not to take any trouble to make it more exalted by allowing exaggerated and misleading statements to go forth as to what he is about to do.

We have recently heard a great deal of Mr. Edison's experiments and promises with reference to the electric light. He startled the world in August last by announcing a great discovery which was to revolutionise the modes of artificial illumination at present in use, but we fear his discovery turned out to be something very like a *ridiculus mus*. Two of his patents have been published; one contains what we must deem a grave scientific error, the other the best authorities consider a mere reproduction of things that have been patented before by Staite, Harrison and others. Up to the present, so far as we can make out, he has done nothing new nor has he produced anything practical. The reports of newspaper interviewers are scarcely worthy of attention. Mr. Edison himself complains bitterly of their importunity and irrepressibility; but why, then, does he seem to stamp them with his approval by distributing their reports from his own laboratory? We cannot but think it a misfortune that he has kept at arms' length the electricians of New York, not one of whom, according to his own statement, has been allowed to enter his laboratory. We are therefore entirely dependent upon the New York press for our knowledge of his progress.

He has laid aside for the present his incandescent light and is experimenting with the Wallace form—his reason being that "everybody knows what the carbon lamp is, and besides it is not my lamp." He is engaged upon a new dynamo-machine—let us hope not his tuning-fork arrangement—but for what reasons he has put aside such perfect machines as the Siemens and the Gramme we are not enlightened. Dr. Hopkinson has recently shown that the Siemens' machine utilises 90 per cent. of the energy thrown into it. The Gramme is not far behind this. Mr. Edison can scarcely hope to improve on either. Again, the Brush and Wallace-Farmer machines are very efficient. Indeed, we scarcely want to improve the machine for producing currents. It is the lamp that needs the thought and work of the inventor, for no lamp yet exists worthy of the name.

The propagation by the daily press of scientific "discoveries" hot from the brain before they are allowed to be cooled down by the test of experiment is an invention upon which we cannot compliment our American friends. It does not conduce to the progress of science nor does it redound to the credit of the discoverer. We are accustomed on this side of the water to learn of new discoveries through the medium of well prepared and carefully digested papers submitted to one of our societies. There are such societies in America, but the records of such societies have to be searched in vain for any experiments or discoveries of Mr. Edison. We think it is matter for sincere regret that he prefers to promulgate what he conceives to be new through "our special correspondent," and the science dished up by these gentlemen is something wonderful to read. Thus says one paper:—

"Being questioned as to the subdivision of the electric light, the inventor said: 'The question is very simple. If you take a lamp in which the voltaic arc is produced from two carbon pencils, the more current you put on the faster the pencils are consumed and the resistance offered is lessened. There necessarily results a great waste of power. If the lamp is limited to 250-candle-light, it costs too much. By my plan the resistance is almost entirely at the lamp. The resistance of the conductor is to the resistance of the lamp as 1 to 100. The resistance of my lamp is as 192 against 1 to the resistance of the carbon lamp. You may consider the question most intelligently by taking a gas-burner as an example. If you have a half-inch gas-pipe and light the escaping gas without putting on a burner, how much gas-light can you get from an adjoining burner? Very little. But if you put in the half-inch pipe a burner, with a pin-hole in it, you get a light without interfering with other burners. The same condition obtains in electric lighting. The carbon lamp represents the half-inch gas-pipe; the pin-hole burner represents my lamp.' 'But is not the electric current exhausted, not with regard to the resisting agent, but according to the square of the distance travelled?' 'No. If you are supplying a mile of wire and then add another mile, the current will be weakened equally throughout the whole line, but not to that extent. If you keep on extending your line, you will have to make your conductor thick and add more power.' 'How do you propose to carry this theory into effect?' 'I shall have, proceeding from the central station, where a steam-engine and a series of dynamo-machines are placed, a

cable, say about an inch in diameter, composed of copper wires, each about one-sixteenth of an inch in diameter. The cable will be laid in a trench immediately under the flagging of the side walk, and near the curb; every twenty-five feet a wire will be dropped to carry the current into a house, and when the terminus of the cable is reached there will be one wire left. Of course it will be necessary to construct the cable according to the number of houses in each district. As a district increases in population the flagging can be taken up, and a section of cable can be placed alongside the original cable, and joined to it at each end. Thus the new houses can be supplied.' 'Will there not be a loss of electricity by induction or the influence of the earth?' 'None whatever. And now I will tell you another thing. It is perfectly easy for me to get a light equal to sixty-six candles from each of my lamps: but I limit them to six.' 'Will not the construction of your station and your cables be very costly?' 'No; and if it were, the profits would warrant the outlay.'"

Copper wires one-sixteenth of an inch in diameter—the same size as those often used for telegraphic purposes—are to convey currents of electricity to light up lamps whose resistances are as 192 to 1 as compared with carbon, or as 100 to 1 as compared with the conductor. The resistance of the copper wire is about 13 ohms per mile. What current will be required to produce a light of 66 candles a mile off under such conditions? An electromotive force of a 1,000 volts would not do it, and the very best machines do not much exceed 100 volts in this respect. Where is the power to come from? Mr. Edison now proposes to have 30 of his new dynamo machines worked by his 80-horse-power steam-engine, lighting up 400 lights. In other words, each machine is to produce about 13 lights, and to absorb $2\frac{2}{3}$ horse-power. This shows that his experience is gradually bringing him down to the limits of our experience in France and England, where for some time past one machine lights up twenty lights, but with an expenditure of 23-horse power. It also shows that he was premature in announcing the solution of the indefinite subdivision of the light, and tha he would have done well to have worked upon the expet rience of others rather than have learnt that experience himself by an immense expenditure of time and money. The electric light, theoretically and practically, is unquestionably more advanced in Europe than it is in America. But even here the progress in lamps is very slight.

Col. Bolton, in a remarkable paper read at the last meeting of the Society of Telegraph Engineers, has shown that electric light manias are not only periodic, but that the very same inventions are to a certain extent, also periodic. Thus he showed that everything that Mr. Edison has patented has been patented before in England.

NOTE AS TO DISTINGUISHING CHARACTERISTICS FOR ILLUMINATED BUOYS

THE plan of illuminating by means of Pintsch's system of forcing gas into floating buoys having now been tried by the Trinity House and by the Harbour Authorities of the Tay, I have lately been engaged in considering the best means of distinguishing one buoy from another.

The plan which occurred to me was *to make the flow of the gas produce automatic intermittent action*, and for this purpose some form of gas meter seemed to promise best. I applied to Messrs. Milne, gas engineers, Edinburgh, to give me their assistance in the matter, and they have succeeded in making a modification of a dry meter which has been tried and found to work very satisfactorily. By this arrangement a small supply of gas keeps a small jet constantly illuminated a little above the principal burner, and when, by the valve, the full supply of gas is turned on to the large burner, it is ignited by the small jet. The periods of light and darkness can be regulated in any desired proportion. The same object may, however, be effected by means of a single burner, the jet being kept burning in the socket.

By means, then, of two separate lanterns, one of which has red panes, and the other either white or green, the following characteristics may be produced :—

Red and white.
Red and green.
Green and white.

If, again, only one lantern be used, we shall have—

Intermittent white.
" red.
" green.

And if to these we add the present single fixed white, red, and green, this would give in all nine characteristics, which would probably be sufficient for any navigation.

It is proper to add that, in order to prevent oscillations of the apparatus, which would take the light out of the sailor's vision, the apparatus and burner should be made to work in gimbals, as in my steamer's lights. If these gimbals were made hollow, the gas could be easily made to pass up to the burner, but a simpler mode would be to use a flexible tube between the regulator and the burner.

THOMAS STEVENSON

GEOGRAPHICAL NOTES

LETTERS from Nordenskjöld have been received by the Governor-General of Siberia. They confirm the news already brought to Europe. The *Vega* steamship has been blocked by ice in a harbour named Kamen, at a short distance from Behring Straits on the east coast of Siberia. This station is easily reached by whalers every year. No doubt the escape of the explorer and his companions will take place without difficulty as soon as the ice breaks up, probably in a few weeks. The news has been brought by native messengers, and everything was going on well on board the *Vega*.

M. WOEIKOF has sent to the French Geographical Society a long and exhaustive memoir on the Oxus question. After having studied the question on the spot, the Russian geographer feels certain that the suppression of the Caspian mouth was produced not by a gradual elevation of the country, but by the accumulation of deposits in the bed of the river, and the immense drainage produced by the development of irrigation in the Khivan Oasis. He feels certain that the restoration of the former state of things would be a very easy work. It would result in the establishment of a new oasis between Khiva and the Caspian Sea. The Oxus being navigable to Balkh, and the Volga being in direct communication with the Baltic, through a system of canals, a water-way would thus be established from St. Petersburg to Balkh, and the stream would connect the Russian capital with the vicinity of their scientific frontier of India. M. Woeikof supposes justly that the restoration of the Oxus to the Caspian would accelerate the retreat of the Aral waters. He believes that shortly after that large operation the area of Aral would be reduced to one-third of its present extent. But he argues that this alteration would not be altogether detrimental to the prosperity of the surrounding countries.

THOUGH there are no journeys of discovery into the interior to record, some useful geographical and topographical work was done in Western Australia by the Surveyor-General's department during the last six months of 1878, as we learn by a report just received from Perth. The position of Mount Welcome at Roebourne, on the north-west coast of the colony, was determined to be

about S. lat. 20° 46′ 6″, E. long. 117° 7′ 55″. The courses of the following rivers were correctly traversed and mapped:—De Grey River, 100 miles; Turner, 25 miles; Yule, 50 miles; Sherlock, 50 miles; Fortescue and tributaries, 300 miles; Robe, 50 miles; Cane, 70 miles; Ashburton and tributaries, 150 miles; making a total of 795 miles. The heights of mountains have not yet been calculated, but a triangulation was made of the country between the De Grey and Ashburton Rivers, covering an area of 30,000 square miles. Maps of the districts above-mentioned are in preparation, but are not yet completed. The report of the work performed during the current half year will, no doubt, contain some interesting information, as a party, under the command of Mr. Alex. Forrest, started in January last to undertake the exploration of the previously unexamined tract of country in the north-west lying between the De Grey and Victoria Rivers.

BARON VON MÜLLER, in a letter to Petermann's *Mittheilungen*, states that Mr. Tietkens, who accompanied Giles on his two last journeys, has left Adelaide for Beltana at the head of a camel expedition fitted out by Mr. Elder for exploration along the region lying inwards from the great Australian Bight. Mr. Tietkens informed us when he was in this country that he was confident that long stretches of fine pasture-land would be found at various parts of this region, and one of his objects is apparently to find these. Baron von Müller speaks highly of Mr. Tietkens's qualifications as an explorer and surveyor, and expects that in the course of the next few years he will do much to add to our knowledge of the geography of the Australian interior.

M. SOLEILLET, the French explorer of North Africa, has arrived at Marseilles from St. Louis, in Senegal. He has been received by the Geographical Society of that city, and will deliver a lecture on the necessity of opening the way between Senegal and Algeria, *viâ* Timbucktoo. It is said that he will, at the suggestion of *Akhbor*, be called to Algiers by the Governor-General before going to Lyons and Paris, where he will deliver lectures on the same subject. In this connection we may state that an interesting ceremony will take place in a few days. The inhabitants of a small country place in the Eure department will remove to another site the grave of René Caillet, the celebrated Timbucktoo explorer, who died in 1838, and was the first laureate of the French Geographical Society. The Society will bear the expenses of exhumation, and send delegates to witness it. One of them will be M. Soleillet.

IN No. 20 of *Globus* of this year is a short article of some interest showing the physical and moral changes in the population of Siberia by the mixture of Russian colonists with the native races.

WE take the following from the *Gardeners' Chronicle*:—Mr. Goldie, the naturalist, who has passed the last eighteen months in New Guinea in search of plants for Mr. B. S. Williams, of Holloway, has, the *Brisbane Courier* states, collected an immense number of animals, birds, and insects, besides valuable botanical specimens, and believes that a large number of these are entirely unknown. He claims to have found an entirely new species of kangaroo. He has brought with him a native from the coast tribes, a good-looking lad of indistinct Malay origin, whose long frizzly hair, tied round with a string, is worn standing straight up. The natives of the inland tribes Mr. Goldie states to be entirely different from those on the coast in both appearance and customs, but all, he says, are friendly and good-natured, and not given to the deeds of ferocity lately detailed by us on the authority of the residents at a *bêche-de-mer* station. Mr. Goldie was of the party that made its way to the coast, crossing about twenty flooded rivers, and losing horses and baggage, and states that although they crossed some high ranges they never reached the dividing range, on the other side of which, the general belief amongst the party was, that payable gold would be found. The natives in the interior are, it appears, so awed at the sight of a white man as to obviate any risk of molestation. The custom of a tribe with whom Mr. Goldie's party came in contact, suggested to them the probable origin of the rumours that have been always current of a race of tailed men in some remote corner of the globe. These natives wear artificial tails of such cunning construction as to entirely mislead a casual observer. They are entirely naked, except for the caudal ornament, which is a plait of grass fastened round their loins by a fine string, and depending behind to about half-way down their legs. Possibly the missing link that has so baffled Darwin has only lately become extinct in New Guinea, and these descendants, ashamed of their degeneracy, keep up the tradition of a noble ancestry by simulating their distinguishing characteristic.

THE Austrian *Monatschrift für den Orient* of May contains an article of much practical and some ethnological value on the Nations of the Turkish Empire as factors in the National Economy; he reviews the condition of the various industries, and the character of the various ethnical elements of the Turkish dominions. Herr A. von Wassberg contributes a paper on the Migrations of the Inhabitants of the Ionian Islands, while Herr Schick continues his elaborate papers on Agriculture in Palestine.

THE May number of Petermann's *Mittheilungen* gives the chief place to a long and careful article by M. Lindeman on the North Coast of Siberia between the Mouths of the Lena and Behring Straits. Herr Lindeman traces the history of exploration in the region from 1630 to the present time, and follows this with a description of the coasts and islands. The article is accompanied by an excellent map in two sheets. Dr. Emin Bey, Governor of the Egyptian Equatorial Provinces, contributes an interesting Journal of a Journey from Mruli to the chief town of Unyoro, abounding with valuable notices on the country and people.

THE March number of the *Bulletin* of the Paris Geographical Society contains, as its first article, the first part of a learned paper by M. de Saulcy on the cities of Upper Louten, the Syria of the Ancient Egyptians. Other papers are on the frontiers of Russia in Central Asia, by M. de Ujfalvy; explorations of the Cunene, by M. Nogueira; and the dried-up rivers of the Dobruja, by Herr F. Kanitz.

NOTES

THE University of Cambridge proposes to confer the honorary degree of LL.D. upon the following, among others:—Mr. Justice Grove, Mr. W. Spottiswoode, President of the Royal Society, Mr. Henry J. S. Smith, Savilian Professor of Geometry, Oxford, Prof. Huxley, Mr. H. C. Sorby, F.R.S. The Rede lecture will be delivered in the Cambridge Senate-house at 2.30 on Wednesday, June 11. The lecturer, the Rev. W. H. Dallinger, has chosen the following subject:—"The Origin of Life as illustrated by the Life Histories of the Least and Lowest Organisms in Nature."

THE Forty-Ninth Annual Meeting of the British Association will commence at Sheffield on Wednesday, August 20, 1879. The President Elect is Prof. G. J. Allman, LL.D., F.R.S., Prof. L.S. Vice-presidents Elect—His Grace the Duke of Devonshire, K.G., F.R.S., the Right Hon. the Earl Fitzwilliam, K.G., the Right Hon. the Earl of Wharncliffe, W. H. Brittain (Master Cutler), Prof. T. H. Huxley, Sec. R.S., Prof. W. Odling, F.R.S. General Secretaries—Capt. Douglas Galton, C.B., F.R.S., Philip Lutley Sclater, Ph.D., F.R.S. Assistant

Secretary—J. E. H. Gordon, B.A. General Treasurer—Prof. A. W. Williamson, Ph.D., F.R.S. Local Secretaries—H. Clifton Sorby, F.R.S., J. F. Moss. Local Treasurer—Henry Stephenson. The following are the sections and their presidents:—A.—Mathematical and Physical Science.—President: George Johnstone Stoney, F.R.S. B.—Chemical Science.—President: Prof. James Dewar, F.R.S. C.—Geology.—President: Prof. P. Martin Duncan, F.R.S. D.—Biology.—President: Prof. St. George Mivart, F.R.S. E.—Geography.—President: Clements R. Markham, C.B., F.R.S. F.—Economic Science and Statistics.—President: G. Shaw Lefevre, M.P., Pres. S.S. G.—Mechanical Science.—President: J. Robinson, Pres. Inst. Mech. Eng. This list of sectional officers will be completed and will be submitted to the General Committee on Wednesday, August 20. The Reception Room will be opened on Monday, August 18, at 1 P.M., and on the following days at 8 A.M., for the issue of tickets to Members, Associates, and ladies, and for supplying lists and prices of lodgings, and other information, to strangers on their arrival. No tickets will be issued after 6 P.M. Tickets for the meeting may also be obtained from August 1 until August 6, on application to the General Treasurer, Prof. A. W. Williamson, British Association, University College, London, W.C. The first General Meeting will be held on Wednesday, August 20, at 8 P.M., when Dr. William Spottiswoode, Pres. R.S., will resign the chair, and Prof. G. J. Allman, F.R.S., President Elect, will assume the Presidency, and deliver an address. On Thursday evening, August 21, at 8 P.M., a *soirée;* on Friday evening, August 22, at 8.30 P.M., a discourse by William Crookes, F.R.S., on Radiant Matter; on Monday evening, August 25, at 8.30 P.M., a discourse by the Rev. W. H. Dallinger, on the Life Histories of the Minutest Organic Forms, and their Bearing on the Doctrine of the Origin of Species; on Tuesday evening, August 26, at 8 P.M., a *soirée;* on Wednesday, August 27, the concluding General Meeting will be held at 2.30 P.M. On Saturday evening, August 23, W. E. Ayrton, Esq., will deliver a lecture to the Operative Classes, on Electricity as a Motive Power. Tickets can be purchased of the local Secretaries. No report, paper, or abstract can be inserted in the Report of the Association unless it is in the Assistant Secretary's hands before the conclusion of the Meeting. A room will be provided for the reception of apparatus and specimens illustrative of papers communicated to the Sections. Excursions to places of interest in the neighbourhood of Sheffield will be made on Thursday, August 28.

WE regret to hear of the decease of M. Edouard Pictet, of Geneva, at the early age of forty-four. He was the son of Prof. F. J. Pictet, of the same city, formerly a writer on neuropterous, insects, latterly a palæontologist, who died about seven years ago. M. E. Pictet inherited his father's scientific tastes, and in 1865 published a "Synopsis des Névroptères d'Espagne," based upon a journey made in that country a few years previously. Latterly he had been much occupied in investigating the physical conditions of the Lake of Geneva, in company with Forel and others of his compatriots; and his official duties, municipal and otherwise, took up much of his time. He visited London at the time when the Loan Exhibition of Scientific Instruments was on view at South Kensington. The family Pictet has included amongst its members several illustrious scientific men, and is one of which Switzerland is justly proud. M. Raoul Pictet, the celebrated investigator of the liquefaction of gases, is a cousin of the subject of this note, and M. H. de Saussure also belongs to a collateral branch of the same family.

THE death is announced of Mr. Thomas Wills, F.C.S., who has acted as secretary to the Chemical Section of the Society of Arts since it was first founded in 1874. Mr. Wills was born in 1850, in Devonshire; he was educated at University College School and at King's College. In the early part of 1868 he became an assistant to Dr. Odling at St. Bartholomew's Hospital, and in the latter part of that year, on Dr. Odling being elected to the Fullerian Professorship at the Royal Institution, Mr. Wills was appointed his official assistant. In 1873 he resigned this post to accept the position of Demonstrator in Chemistry at the Royal Naval College. The subject to which Mr. Wills specially devoted himself was the application of chemistry to the manufacture of gas, and on questions connected with this subject he was rapidly becoming an authority. He was a constant contributor to the *Transactions* of the Chemical and other societies. For several years he acted as secretary to Section B (Chemistry) of the British Association, and he was a member of the Association Committee for ascertaining the best methods of improving the illuminating power of coal-gas. His most recent piece of work was in connection with the subject of electric lighting. Dr. Tyndall, in giving evidence upon the electric light before a Committee of the House of Commons, referred to Mr. Wills as having discovered that oxides of nitrogen were given off by the voltaic arc, thus rendering the light to that extent injurious.

IN the Paris Academy, Dr. Oppolzer has been elected a Corresponding Member in the Astronomical Section in place of the late Prof. Argelander, and M. Alphonse Favre in place of the late Prof. Leymerie in the Section of Mineralogy.

THE professors of the Museum of Paris have presented two candidates for filling the place vacated by the death of Claude Bernard, who was professor of general physiology in the establishment. The first candidate is M. Boubez, of the Institute, and the second M. Moreau.

A GENERAL MEETING of the Mineralogical Society of Great Britain and Ireland will be held at the Meteorological Office, 116, Victoria Street, on Tuesday, June 3, at 8 P.M., when the following papers will be read:—On abriachanite, a new Scottish mineral, by Prof. M. F. Heddle and D. W. H. Aitken; on haughtonite, a new mica, by Prof. M. F. Heddle; on christophite from St. Agnes, Cornwall, by J. H. Collins, F.G.S.; minerals from Japan, by John Milne, LL.D., and T. Davies, F.G.S.; additional note on penwithite, by J. H. Collins, F.G.S. The chair will be taken by Prof. T. G. Bonney, M.A. Other communications intended to be read at this meeting should be sent to J. H. Collins, secretary, at the Scientific Club, 4, Savile Row, London, W., not later than Saturday, May 31.

THE first public act passed by the U.S. Congress during the present session, was one making an appropriation of 200,000 dollars for the construction, under the direction of the Secretary of the Treasury, for the National Board of Health of a vessel provided with suitable refrigerating apparatus, for the purpose of determining the possibility of destroying the yellow fever infection by intense cold. The act as first introduced had special reference to the apparatus of Prof. Gamgee, but as passed it is within the power of the Secretary to select any device that will, in the opinion of the National Board of Health, best answer its purpose.

PROF. DUGES, of Mexico, in a recent letter to the Smithsonian Institution, speaking of the enormous numbers of the common cow-bird, or *Molothrus pecoris*, in his neighbourhood, refers to a certain flight supposed to have been about 12,000 yards in length, six yards wide, and probably over a yard deep. He estimates the number contained in it to be from 9,000,000 to 10,000,000. A flock of 1,000 or 2,000 of these birds is very common, generally mixed with the *Xanthormus icterocephalus*, and to some extent with the red-winged blackbird.

WE learn that Dr. Edouard Bornet, of Paris, eminent for his researches on the structure and reproduction of algæ, and author

of other works on that order, and Prof. Heinrich Gustav Reichenbach, fils, Director of the Botanic Gardens, Hamburg, alike distinguished for his special knowledge of, and publications on, the Orchidaceæ, have been elected Foreign Members of the Linnean Society.

OF eleven female candidates who presented themselves for the first examination for the degrees of London University, six were placed in the division of honours, four were declared to be entitled to exhibitions, and one was second in the whole list of candidates. There were only two failures.

DR. SWAN M. BURNETT, of Washington, has recently made some examinations for the purpose of ascertaining whether the negro in the United States is affected with colour-blindness to the same degree as the white race. He has examined 3,050 coloured children, from six to eighteen years of age, in the public schools of the district of Columbia, of whom 1,359 were males, and 1,691 females. Of these, twenty-two boys were colour-blind (or 1·6 per cent.), and two girls (or 0·11 per cent.) The percentage of colour-blindness among the whites in an aggregate of about 40,000 examinations is 3 per cent. for males, and 0·26 for females. The negro appears, therefore, to be less liable to this defect than the white race. The examinations were made in strict accordance with the plan proposed by Prof. Holmgren, of Upsala, Sweden, and used so extensively in making similar examinations in Europe.

A NUMBER of Jablochkoff candles have been employed by the French government, for illuminating, by night, an exhibition held at the École des Beaux Arts, for the benefit of schools. The success is so great, that it has been proposed by M. Turquet, Director of Fine Arts, to open by night the exhibition of Pictures, held now at the Palais de l'Industrie. It is stated that not less than 250 candles will be lighted on this occasion, which will require an engine of more than 300 horse-power. But the expense, although considerable, will be nothing in comparison with the receipts expected. The arrangements will be made during the temporary closing at the end of May, and the electric light be put in operation during the month of June. It is likely that the arrangements will be utilised by the Exhibition of Arts applied to Science, which will be held from July to November.

THE select committee to investigate into the explosion on board Her Majesty's armour-plated turret-ship *Thunderer* propose to make their experiments in the most public manner, in order fully to establish the stability of the guns constructed on the Woolwich system under all the conditions of the service, and the liability of any gun to be destroyed by unfair means. The burst gun has been taken into the inspection department for examination, and the sister 38-ton gun will be taken to the proof butts in the marshes to be fired.

THE June *Scribner* will contain the first of a series of articles on "Edison and his Inventions," by Mr. Edwin M. Fox. The opening paper will be devoted to the electro-motograph and its applications. The six-years' growth of this remarkable invention will be described by Mr. Fox with much incidental light on the inventor's methods of work.

THE *Colonies and India* furnishes some interesting particulars respecting the so-called "vegetable ivory," which is now so much used as a substitute for ivory. The vegetable ivory nut is the produce of a species of palm found wild in South America and Africa. Inside the hard shell is the white kernel, which being softer than ivory and easily carved, as well as readily dyed, and being less brittle than bone, is largely used in making buttons, &c. The unripe fruit consists of a green shell, containing a watery fluid, which, as the nut ripens, gradually thickens until it becomes a pulpy mass, and eventually hardens into solid matter. The water, though bitter to the taste, is wholesome, and often renders invaluable service to travellers, who cannot otherwise obtain water to drink. The tree (*Phytelephas macrocarpa*) on which the fruit grows is unlike an ordinary palm, having little or no stem and drooping downwards, especially when the weak branches are overweighted by the six or seven bunches of nuts, each containing six or seven seeds, inclosed in thick heavy shells and outer sheath, and weighing altogether from 20 to 24 lbs.

A RECENT valuable memoir by Prof. Stefan to the Vienna Academy treats of the relation between radiation of heat and temperature. In the first part he discusses Dulong and Petit's experiments, from which the conclusion was drawn that the amount of heat radiated from a body increases in a geometrical progression, when its temperature increases in an arithmetical. Prof. Stefan points out that the observations of these physicists may be calculated with great approximation by another very simple formula, according to which the amount of heat radiated from a body is proportional to the fourth power of its absolute temperature. It is shown that while the law of geometrical progression corresponds to Dulong and Petit's numbers better than that of the fourth powers, these numbers (because of defects in experiment) are not suited for rigorous proof of the law as to heat radiation. Further, it is shown that the formula of the fourth powers agrees with the observations of Provostaye and Desains much better than that of Dulong and Petit. In the second part of the memoir, cooling experiments are utilised for determination of heat-radiation in absolute measure. In the third it is shown that the formula of the fourth powers agrees fairly well with Draper's experiments on heat radiation of a glowing platinum wire, and Ericson's on that of a glowing block of iron. The fourth part contains some remarks on the sun's temperature. From the intensity of solar radiation as determined by Pouillet, the emissive power of the sun being considered = 1, we obtain, according to the formula of the fourth powers, the sun's temperature = 5580°. Nearly the same number comes by this formula from Soret's comparative determinations of the radiation of the sun and that of a glowing disk of zirconium.

A NEW grass, *Reana luxurians*, has been imported into Ceylon from Java, and is stated to be doing well, having attained a height of 8 feet in three months. It is said to contain a large amount of saccharine matter, and cattle and horses eat it freely.

EXTRAORDINARY finds of gold have lately occurred in the gold-fields of Dutch and French Guiana and are causing great excitement.

A RICH deposit of lead and silver has just been discovered near the Thames River, New Zealand. The ore is reported to contain 50 per cent. of lead, with about two pounds worth of silver, and 9 dwt. 13 grs. of gold per ton.

ACCORDING to the Japan papers, a singular innovation has lately taken place in an ancient branch of the trade of the country. Mixadzu, a town in the province of Tanbano-kuni, has always been famous for the manufacture of crape, the principal industry in the province. Hitherto, however, the crape has been manufactured from Japanese silk, but it has recently been discovered that the kind of silk required can be imported from Corea of better quality and much cheaper than it can be procured at home. A number of Japanese merchants have, therefore, formed themselves into a company with the object of manufacturing crape from Corean silk, and have already despatched one of their number to Corea to make the necessary arrangements.

ON Tuesday last week an enormous avalanche descending from the Jungfrau swept through the valley of Stufenstein, carried away a whole forest, and created the utmost consternation in the neighbourhood. So far as is known no lives were lost.

THERE has been a slight eruption of Vesuvius for some days.

A VERY distinct Fata Morgana was observed above the village of Zhor, near Kozlau in Bohemia, on the 2nd inst.

M. JULES FERRY, the French Minister for Public Instruction publishes a report on the re-establishment of the Museum of Pedagogy, which was created by M. Jules Simon at the Ministry of Public Instruction, and described in NATURE at the time. This report shows that the original idea of such a collection must be attributed to M. Jullien of Paris, one of the best pupils of the celebrated Pestalozzi, who established it in 1817. The direction of the new museum will be given to a general inspector of primary instruction specially appointed for the purpose. This museum will be also a central library for primary education in France.

WE have received two numbers (February and March) of the *College Journal*, issued in connection with the Georgetown (R.C.) College, U.S. The latter number contains an article resuming some of the more recent conclusions with regard to sun-spots.

WE have on our table the following books:—"Description of Vertebrate Remains," Prof. Joseph Leidy (Collins, Philadelphia); "Characeæ Americanæ," part 1 (Timothy F. Allen, New York; "Sport in British Burmah, Assam, and the Cassyah and Jyntiah Hills," Lieut.-Col. Pollok (Chapman and Hall); "Obituary Notices of Astronomers," Edwin Dunkin (Williams and Norgate); "On the Nature of Life," Ralph Richardson (H. K. Lewis); "The Gault," F. G. Hilton Price (Taylor and Francis); "Ausgestrahlte Licht," Edw. L. Nichols (E. V. Huth, Göttingen); "The Students' Text-Book of Electricity," Henry M. Noad (Crosby Lockwood); "Atlas of Histology," part 3, E. Klein and E. N. Smith (Smith, Elder); "Organic Chemistry," Hugh Clements (Blackie and Sons); "Evolutions Old and New," S. Butler (Hardwicke and Bogue); "Treatise on Natural Philosophy," vol. i. part 1, Thomson and Tait (Cambridge University Press); "Mechanics," R. S. Ball (Longmans); "Health and Occupation," B. W. Richardson (S.P.C.K.); "Electric Lighting," J. N. Shoolbred (Hardwicke and Bogue); "Hydro-Incubation," Thos. Christy (Christy and Co.); "Principles of the Algebra of Logic," Alex. Macfarlane (Douglas); "Geological Map of Northumberland," G. A. Lebour (Andrew Reid); "The Ibis" (General Index 1859–76), Ed. O. Salvin (Van Voorst); "Middleton's Impeachment of Modern Astronomy" (Judd and Co.); "Hints on the Pronunciation of the French Language," L. J. V. Gerhard (Hachette and Co.); "Analytical Chemistry," Dr. John Muter (Wm. Baxter); "Pharmaceutical Chemistry," Dr. John Muter (Wm. Baxter); "Manchester Science Lectures for the People, 1877, 1878, 1879" (John Heywood); "Australasia," A. R. Wallace (E. Stanford).

THE additions to the Zoological Society's Gardens during the past week include a Rhesus Monkey (*Macacus erythræus*) from India, presented by Mr. H. Winsor; a Vulpine Phalanger (*Phalangista vulpina*) from Australia, presented by Mr. A. Elder; a Ring-necked Parrakeet (*Palæornis torquatus*) from India, presented by Mr. F. S. Prince; a Herring Gull (*Larus argentatus*), European, presented by Mr. C. H. de Loecker; a Rough Terrapin (*Clemmys punctularia*) from Trinidad, presented by Surgeon-Major C. J. Weir; a Puma (*Felis concolor*) from America, purchased; two Squirrel Monkeys (*Saimaris sciurea*) from Guiana, two Plantain Squirrels (*Sciurus plantani*) from Java, a blue Jay (*Cyanocitta cristata*) from North America, an Ariel Toucan (*Ramphastos ariel*) from Brazil, a Sclater's Curassow (*Crax sclateri*) from South America, deposited; a Zebu (*Bos indicus*), two Geoffroy's Doves (*Peristera geoffroyi*), a Yellow-legged Herring Gull (*Larus leucophæus*), bred in the Gardens.

ON THE INFLUENCE OF PRESSURE UPON THE SPECTRA OF GASES AND VAPOURS

HERR G. CIAMICIAN has recently communicated to the Vienna Academy the results of a series of interesting experiments made with a view of investigating the influence of pressure upon the spectra of gases and vapours. From the somewhat lengthy report we gather the following data, which may prove acceptable to those of our readers who are actively engaged in spectroscopic research. The spectra of the three halogens, chlorine, bromine, and iodine, show on the whole the same peculiarities when the pressure is increased. The bright lines become diffused, sometimes a little broader, without, however, changing into bands. Besides this, a continuous illuminated background appears, which increases in brightness with the pressure, and which often overpowers the lines. This is particularly the case with iodine, where, eventually, nothing but a continuous spectrum is seen; while with chlorine and bromine certain lines yet remain brighter than the continuous light. The behaviour of certain lines in the red part of the spectra of chlorine and bromine is remarkable, as they retain their original sharpness and fineness under any pressure.

The spectrum of sulphur does not change at all under increased pressure, the lines retain their full sharpness, and a continuous bright background appears only at the red end of the spectrum. In the case of phosphorus and arsenic there is no reaction at all, as here even the continuous background does not appear. Herr Ciamician thinks that it has been overlooked hitherto that arsenic under a moderate pressure, and without a Leyden jar being inserted into the electric current, gives a spectrum of the first order, viz., a nearly continuous one, which, when the density becomes greater and the Leyden jar is inserted, disappears, and is replaced by a line spectrum.

Metals behave very differently to the non-metals just mentioned; here a real band-like extension of the spectral lines takes place, while the continuous light remains subdued. In the mercury spectrum the enlargement of the green and violet lines are specially noteworthy. In the sodium spectrum Herr Ciamician could observe the enlargement, which is very considerable, only with the *reversed, i.e.*, dark D line, as he could not observe the spectrum emitted in any other way than through a layer of sodium vapour. Under high pressure sodium gives a continuous background in the immediate neighbourhood of the D line, and upon this the reversed D line appears. At first it is seen as a double line, but soon afterwards the two lines flow into one in consequence of the enlargement; the dark band thus formed becomes wider and wider, until it finally covers the whole background which appeared in continuous light.

SCIENTIFIC SERIALS

THE *Revue Internationale des Sciences* (April, 1879) contains the following papers:—On symbiosis, by Prof. de Bary.—On the physical and intellectual evolution of woman among the different races, by M. Zaborowski.—On the chromatic function of the octopus, by Dr. L. Frédéricq.—On the source of muscular power, by A. Flint.—On the constitution of the blood plasma, by Dr. L. Frédéricq.—On the nature of lichens, by Dr. J. Müller.—On the entozoa of insects, by Osman Galeb.

THE *Verhandlungen der naturforschenden Gesellschaft zu Freiburg in Baden* (vol. vii. part 3) contains the following papers:—On a generalisation of Jacobi's reversion problem of Abel's integral, by F. Lindemann.—On the determination of the coefficient of elasticity through the bending of short rods, by K. R. Koch.—Microscopical observations on the growth and melting away of alum crystals in solutions of isomorphous substances, by F. Klocke.—On an automatic water and air-pump, by L. von Babo.—New discoveries in the Freiburg flora, by J. Schill.—On some minor actions of wind, by F. C. Henrici.

THE *Archives des Sciences physiques et naturelles* (April, 1879) contains the following papers:—Remarks on the geological review of Switzerland for 1878, by Ernst Favre.—On the *seiche* occasioned by the cyclone of February 20 last, by Prof. Ph. Plantamour.—On the hurricane of February 20, by F. A. Forel.—On the presence of tannine in vegetable cells, by J. B. Schnetzler.—On the meteorology of the Presidency of Bombay, by Ch. Chambers.—Researches on electricity, by Gaston Planté.—On the compounds derived from oxypropylbenzoic acid, by R.

Meyer and J. Rosicki.—On a new glucosid obtained from *Lupinus luteus*, by E. Schulze and J. Barbieri.—On the action of bromine upon some paraffins of high molecular weights, by V. Merz and F. Weith.—On cantharic acid, by J. Piccard.—On some reactions of silver ultramarine, by K. Heumann.—On the reactions of nitrosyl silver, by W. Zorn.—On the transformation of undecylenic acid into undecylic acid ($C_{11}H_{22}O_2$), by F. Krafft.—On the stipulæ and their *rôle* in inflorescence and the flowers of plants, by M. Clos.

SOCIETIES AND ACADEMIES

London

Royal Society, May 8.—"On the Relation between the Diurnal Range of Magnetic Declination and Horizontal Force, as observed at the Royal Observatory, Greenwich, during the years 1841 to 1877, and the Period of Solar Spot Frequency." By William Ellis, F.R.A.S., Superintendent of the Magnetical and Meteorological Department, Royal Observatory, Greenwich. Communicated by Sir George Airy, K.C.B., F.R.S., Astronomer-Royal.

In this paper the author draws attention to the long series of magnetical observations which have been made at the Royal Observatory under the direction of Sir George B. Airy, K.C.B., Astronomer-Royal, and remarks that examination of the Greenwich records shows that, in addition to the ordinary diurnal and annual changes, there appears to exist, in the magnetic diurnal ranges, an inequality, resembling in its features the well-established eleven-year sun-spot period.

This is not by any means the first time that such relation has been discussed, it being, by some investigators, considered to be already sufficiently well proved. But it appeared that the long series of Greenwich observations might be well applied as an independent test of the accuracy of the supposed relation.

The results for declination and horizontal force only are used, the strict continuity of the record by the vertical force instrument being somewhat broken.

The monthly mean diurnal range of declination, or of horizontal force, is taken to represent the magnetic energy of the month relatively to other months, and smoothed curves of the magnetic numbers and Dr. Wolf's sun-spot numbers are drawn, which show a remarkable similarity.

The epochs of minimum and maximum being tabulated, it is found that, on the average, the mean magnetic epoch follows the sun-spot epoch by 0·27 of a year. By another method of tabulation the difference becomes reduced to 0·10 of a year.

It seemed further desirable to ascertain whether the more fitful changes of the phenomena in any way also correspond. To make this comparison, the magnetic numbers, instead of being smoothed, as before described, were now cleared only of the *average* annual inequality, and compared with the *actual* monthly sun-spot numbers. Curves are given, founded on these numbers, and they show some very remarkable correspondences between the more rapid sun-spot and magnetic variations, especially between the years 1869 and 1873.

Further inquiry seems to point to a variation in the annual inequalities of magnetic diurnal range.

The following are the general conclusions supposed to be derived from the whole inquiry:—

1. That the diurnal ranges of the magnetic elements of declination and horizontal force are subject to a periodical variation, the duration of which is equal to that of the known eleven-year sun-spot period.

2. That the epochs of minimum and maximum of magnetic and sun-spot effect are nearly coincident; the magnetic epochs, on the whole, occurring somewhat later than the corresponding sun-spot epochs. The variations of duration in different periods periods appear to be similar for both phenomena.

3. That the occasional more sudden outbursts of magnetic and sun-spot energy, extending sometimes over periods of several months, appear to occur nearly simultaneously, and progress collaterally.

4. That it seems probable that the annual inequalities of magnetic diurnal range are subject also to periodical variation, being increased at the time of a sun-spot maximum, when the mean diurnal range is increased, and diminished at the time of a sun-spot minimum, when the mean diurnal range is diminished.

Conclusions Nos. 1, 2, and 3 appear to be sufficiently certain, but the evidence in favour of No. 4 is not so decisive.

Chemical Society, May 15.—Mr. Warren de la Rue, president, in the chair.—The following papers were read:—On nitrification, part ii., by R. Warington. The author finds that light hinders the conversion of ammonia salts into nitrites and nitrates, by the nitrifying ferment; the presence of carbonate of calcium is indispensable; nitrification is stopped by a temperature of 40° C.; there is a period of incubation after the addition of the ferment, during which no effect is produced; this period is increased by using stronger solutions of ammonia salts, but diminished by raising the temperature; in some cases nitrites, in others nitrates are formed.—On the alkaloids of the Veratrum family, part iii., by C. R. A. Wright and A. P. Luff. The authors have obtained two new crystalline alkaloids, pseudojervine, melting at 299°, and rubijervine, melting at 237°, and a new amorphous base veratralbine, from Veratrum album.—On the alkaloids of the Veratrums, part iv., by C. R. A. Wright. From Veratrum viride the author has obtained jervine, pseudojervine, rubijervine, veratrine, and cevadine.—On the alkaloids of the aconites, part iv., by C. R. A. Wright and A. P. Luff. The authors have examined Japanese aconite roots, and obtained a base Japaconitine melting 185°, resembling aconitine. By saponification a new base Japaconin was formed. The yield of alkaloids from Japanese aconite is about three times that from *A. napellus*.—On the action of hydrochloric acid on manganese dioxide, by S. U. Pickering. The author criticises, and in the main disagrees with the conclusions of W. W. Fisher as to the existence of manganese tetrachloride.—On some reactions of the ammoniochloride of magnesium, known as magnesia mixture, by H. D'Arcy Power. The author has observed that potassium salts, and especially potassium iodide, precipitate magnesium hydrate from this solution to an extent equal to 46 per cent. of the magnesia present.—The composition of cow's milk in health and disease, by A. Wynter Blyth. The author has separated from whey two alkaloidal bodies, by precipitation with nitrate ot mercury, galactine, and lactochrome; also a supposed glucoside, precipitated by tannin. He gives details as to the composition of milk from healthy and diseased cows, and concludes that a cow suffering from very acute disease may give milk differing in no essential feature from normal milk.—On the effect of alcohol on saliva, and on the chemistry of digestion, by W. H. Watson. Alcohol hinders markedly the conversion of starch into sugar by saliva; a trace of hydrochloric acid, on the other hand, increases the rapidity of the conversion.

Anthropological Institute, April 29.—Mr. E. Burnet Tylor, D.C.L., F.R.S., president, in the chair.—The following new Members were announced:—W. S. Duncan and Edmund Knowles Binns.—A paper was read by Col. H. Yule, C.B., entitled "Notes on Analogies between the Indo-Chinese Races and the Races of the Indian Archipelago." The author first stated that the paper was written abroad some nine or ten years ago, and had been unaltered since. A large number of analogous manners and practices were adduced, common alike to the peoples of the two regions, which Col. Yule, in conclusion, considered would singly be of no value as arguments for some original close bond of kindred between the races of the Indo-Chinese countries and those of the Archipelago. But when thus accumulated they must surely be admitted to have great weight, and to be too numerous and striking, considering the comparative contiguity of the regions occupied by those races, and the physical resemblances which often occur among those of them, the most remote from one another to be due merely to the parallel development of isolated bodies of men in like stages of growth.—A paper was also read by the Rev. James Sibree, jun., of the London Missionary Society, upon relationships and the names used for them among the peoples of Madagascar, chiefly the Hovas, together with observations upon marriage customs and morals among the Malagasy. It was remarked that in the Malagasy language there are in many classes of words strange deficiencies, as compared with English, while, at the same time, in other groups there is great fulness and minuteness of distinction. Notice was taken of the low standard of morals generally prevailing through the island, and of the evidence of this given by the dictionary, in the absence of such words as chastity, purity, and allied terms. The paper concluded by a description of the class distinctions among the Hovas, there being three main divisions: the Andrians or nobles, the Hovas or commoners, and the Andevo or slaves, the subdivisions of which were also pointed out, together with the restrictions upon marriage between the different ranks of native society.

Entomological Society, May 7.—J. W. Dunning, M.A., F.L.S., vice-president, in the chair.—M. N. Joly, of Toulouse, was elected a Foreign Member.—Mr. H. J. Elwes exhibited a collection of lepidoptera made in Asia Minor by Dr. Staudinger.—Dr. Wallace exhibited a collection of lepidoptera made by his son in the United States of Columbia.—Mr. W. L. Distant exhibited a West African specimen of the large water-bug, *Hydrocyrius Columbiæ*, Spin., common also to Madagascar and the Neotropical region; and read extracts from a letter received from Calabar district as to its power of attaching itself to stones by its tarsal claws, and even lifting large ones by the same means.—The Secretary exhibited an alcoholic specimen of a trichopterous insect belonging to the *Leptoceridæ*, forwarded from Brazil by Dr. Fritz Müller, and remarkable on account of its showing very distinctly the branchiæ lately discovered in the imago stage of this order by Dr. Palmèn.—Dr. Wallace stated that, as the result of large numbers of experiments upon the rearing of silk-moths of various species, he had come to the conclusion that the ordinary *Bombyx mori* is the only species that could be profitably reared in this country.—Sir John Lubbock forwarded for exhibition two species of *Bombycidæ* from Adelaide, South Australia, together with their cocoons, eggs, and larvæ, and a letter from Mr. G. Francis giving details of the life-history of the specimens exhibited.—Mr. McLachlan read a note received from Mr. W. J. Wilson, residing in North-west India, referring to the appearance of locust-swarms in that district.—Dr. Fritz Müller communicated a paper entitled "Notes on the Cases of some South Brazilian Trichoptera."—Mr. Wood-Mason read a paper entitled "Morphological Notes bearing on the Origin of Insects," and exhibited microscopical preparations in illustration.

Victoria (Philosophical) Institute, May 19.—After the election of several new members, a paper on the ethnology of the Pacific was read by the Rev. S. J. Whitmee, illustrated by diagrams and an ethnological map of the Pacific, which Mr. Whitmee had prepared during his long residence in many of the various groups of islands in that ocean; many present afterwards joined in the consideration of the paper, in which the author gave many reasons for believing that in earlier times a considerable intercommunication took place between the Continent and the islands, and that there was no reason for believing that, from the evidence already obtained, any arguments could be drawn against the unity of the human family.

PARIS

Academy of Sciences, May 12.—M. Daubrée in the chair.—The following papers were read:—On vision of colours, and particularly the influence exerted on vision by coloured objects moving circularly, when observed comparatively with similar objects at rest, by M. Chevreul. A third extract from his work on the subject.—On the bases derived from aldol-ammonia, by M. Wurtz.—Note relative to a communication of M. Meunier; and on similar water-spouts observed recently, by M. Faye. The accounts are cited as giving strong confirmation of his theory.—Maps of the coast of Tunis and Tripoli, by M. Mouchez. These eleven maps, covering about 250 leagues of coast, are the outcome of M. Mouchez's recent voyage in the *Castor*. The Gulf of the Greater Syrtis seems destined to be always desert, and a dread to navigators; the fanatical and hostile Nomads seem to visit its borders only to pillage wrecked vessels. The coasts of the lesser Syrtis are more hospitable under the government of Tunis. In view of the expensiveness of M. Roudaire's scheme, M. Mouchez wishes it were undertaken by others than the French. The tides are very sensible and pretty regular in the Gulf of Khabs. Unfortunately the natives destroyed the scales erected, so that the author can only give approximate figures.—On the history of the theory of the thrust outwards in slanting arches, by M. de la Gournerie.—On the transformations of the second order of hyperelliptic functions, which, applied twice successively, produce duplication, by M. Borchardt.—M. Oppolzer was elected Correspondent in Astronomy in room of the late M. Argelander, and M. Favre Correspondent in Mineralogy in room of the late M. Leymerie.—On the effects of inhalation of spirit of turpentine, by M. Poincaré. His observations were both on workmen and animals. The disorders produced in the former are headache, giddiness, irritability, pricking and tearfulness in the eyes, and weakness of sight, irritations of pharynx and larynx, vomiting, &c. Through habit, men get to bear the vapours longer. The troubles are more intense and constant with spirits of turpentine from Hungary and America than with those of French origin. Animals which died from the acute poisoning in confined space generally showed congestion and free drops of the condensed spirit in the blood.—On the means used by M. Gyldén for regulating trigonometric developments representing perturbations, by M. Callandreau.—On a new form of co-ordinates in the problem of two bodies, by M. Gyldén.—On two applications of the method of MM. Fizeau and Foucault. These rest (1) on substitution of a known system (in which the distance of the lines is determined by the condition that the wave-length of D is 0·0005888), and (2) on the use of formulæ of dispersion. The first application is the measurement of the thickness of a parallel crystalline plate; the second, study of the dispersion of double refraction of a plate.—Thermal researches on silicic ether, by M. Ogier. Its heat of formation may be determined either by analysis or by synthesis. The one method gave − 11·56 cal., the other − 11·44 cal.; mean − 11·5 cal. The heat of vaporisation of silicic ether is, for 1 equivalent, 7·0 cal.—Action of ammoniacal salts on some metallic sulphides, and application of the facts observed to mineral analysis, by M. De Clermont.—On a new mode of formation of glycocol by means of nitracetic ether, by M. De Forcrand.—On the production of conidia by a bacillus, by M. Engel. This was observed in June, 1876, when some of the numerous bacilli in the blood of a woman who had died in childbed were placed in Pasteur's nutritive liquor. M. Engel designated the bacillus as *puerperalis*.—Influence of heat on the functions of the nervous centres of the crayfish, by M. Richet. Either by asphyxia, or (better) by temperatures varying from 23° to 36°, one may paralyse separately the different functions of the ganglionic nerve centres; the voluntary, intellectual innervation disappears first at 23° to 26°; the reflex innervation, properly so-called, disappears at 27° to 29°; and lastly, the innervation of respiration disappears at 28° to 30°.—Regeneration of nerves of the anterior epithelium of the cornea, and theory of continuous development of the nervous system, by M. Ranvier. The regeneration of cells of the anterior corneal epithelium precedes that of the nerves, showing that the reproduction and nutrition of the epithelial covering of the cornea are independent of the nervous system. The last nervous ramifications tend by their nature to grow continually at the periphery.—On the respiratory apparatus of Ampullaria, by M. Jourdain.—On a new genus of Anouran Batrachian of Europe, by M. Lataste. This has been observed in Spain by M. Bosca. M. Lataste gives it the name *Ammoryctis*; it takes rank in the family of *Alytidæ*, of the sub-order of *Mediogyrinides*.—On the peculiar amyloid matter in the asci of some Pyrenomycetes, by M. Crié.—On the discovery of a jaw of Cainotherium in the gypsums of Aix (Bouches du-Rhone), by M. Cairol. On borings made in view of formation of an interior sea in Algiers, by M. Roudaire. The new results are of the same order as the former.—Water-spouts at Vitry-sur-Seine, by M. Meunier.—M. Hervé Mangon presented the first volume of a "Statistical Atlas of Water-Courses, Manufactories, and Irrigations of France;" also a work by M. Demontzey, on the works of replanting and returfing mountains.

HOW TO LEARN A LANGUAGE

How to Learn Danish (Dano-Norwegian). By E. C. Otté. (London: Trübner and Co., 1879.)

THE tourists who now crowd into Norway summer after summer are apt to find that a better acquaintance with the language of the country is required from them than is the case in the more frequented parts of Europe. They ought, therefore, to be grateful to Miss Otté for having provided them with an excellent manual for acquiring the necessary knowledge, since Danish is the language not only of Denmark but of the towns of Norway also, though more or less varying dialects are spoken by the peasants in the isolated dales. The manual is composed according to the Ollendorffian method; but a systematic grammar and rules for pronunciation are appended at the end, and the whole book is prefaced by an interesting and instructive introduction.

The Appendix corrects the chief defect of the method of teaching foreign languages initiated by Ollendorff. This is its neglect to pay proper attention to so very important a matter as pronunciation and phonetics. Ollendorff seems always to presuppose the presence of a teacher who is either a native or else thoroughly acquainted with the phonetic peculiarities of the language he teaches. No doubt in learning a foreign tongue it is advisable to have such a teacher close at hand; but sometimes this is not possible, and the possibility is admitted by Ollendorff himself when he claims that his method will enable the pupil to dispense with a teacher altogether. It is clear, however, that Miss Otté, though she comes to the rescue of the student in regard to the pronunciation of Danish, has never paid very close attention to phonetics. The learner who tried to speak Danish in accordance with the rules of pronunciation she has laid down for him, would speak it with a very Anglicised accent indeed. Not a word is said even of that marked characteristic of Danish, the "stödtone" or glottal catch. For Danish pronunciation, it is desirable to consult Mr. Sweet's article in the *Transactions* of the Philological Society, 1873-4.

The very fact that so integral a part of language as phonology should be thus passed over in works intended to promote a conversational knowledge of foreign idioms shows the unsatisfactory character of our present mode of teaching languages, even at its best. It is based rather on empirical haphazard than on scientific principles. The method and results of comparative philology have as yet had but little influence on practical education. It is the old story of the divorce between the man of science and the man of practice, and, as usual, education suffers. If we would know how languages ought to be learned and studied we must give heed to the lessons of science which are also the lessons of nature.

Language consists of sounds, not of letters, and until this fact is thoroughly impressed upon the mind, it is useless to expect that languages will ever be studied aright. Language, moreover, is formed and moulded by the unconscious action of the community as a whole, and like the life of the community is in a constant state of change and development. Consequently we cannot compress the grammar of a language into a series of rigid rules, which, once laid down by the grammarian, are as unalterable as the laws of the Medes and Persians. On the contrary, grammar is what the community makes it; what was in vogue yesterday is forgotten to-day, what is right to-day will be wrong to-morrow. But above all, language, except for the purposes of the lexicographer, consists not of words but of sentences. We shall never be able to speak a foreign tongue by simply committing to memory long lists of isolated words. Even if we further know all the rules of the grammarians, we shall find ourselves unable in actual practice to get very far in stringing our words together or in understanding what is said to us in return. This was not the way in which we learnt our own mother-tongue, and if we would learn another language easily and correctly we must set about learning it as we learnt our own.

Ollendorff had the merit of seizing hold of this important fact, and to this his system owes the success it has obtained. Let the pupil first saturate his mind, as it were, with sentences or phrases; there will be plenty of time afterwards to analyse these into words and grammatical forms. We must begin with the whole, not with its parts; analysis is the task of science, not of practical education. But in both alike we must start with the known, or the best known; the unknown or less known to which we work back will differ according as our object is a scientific or a practical one.

If our object is the practical one of acquiring languages the less known will be those idioms which present special difficulties either through the strangeness and unfamiliarity of their structure and modes of expressing thought, or still more through their being now extinct. To learn a dead language in anything like a proper way is a very hard matter. We must first be able to think in other languages than our own and know what language really is; in other words, we must have a sound acquaintance with living tongues. Until we can realise that Greek and Latin are in no essential respect different from English, or French, or German, that they do not consist in a certain number of forms and rules learned by rote out of a school-grammar, or even in the polished phrases of a few literary men, but in sounds once uttered and inspired with meaning by men who spoke and thought as we do, the long years spent over Latin and Greek are as good as wasted. It were far better to fill our minds and store our memories with something which will be practically useful to us in after life and at the same time afford that mental training of which we hear so much. To begin our education with the dead tongues and afterwards fill up the odd intervals of time with a modern language or two is to reverse the order of science and nature. The necessary result is to produce a total misapprehension of the real character of speech, a permanent inability to gain a conversational knowledge of foreign idioms, and a false and generally meagre acquaintance with the classical languages themselves. It is not wonderful that the small modicum of Latin and Greek acquired during years of painful work at school should so frequently disappear altogether as soon as school is left, and considering the erroneous views this small modicum of learning implies it is perhaps hardly to be regretted that it should.

When a conversational knowledge of a foreign idiom

has once been obtained and the pupil is able to think in another language than his own, the analysis and study of the idiom should be carried on in the light of comparative philology. He should be taught to see that the apparently arbitrary phenomena of language are all subject to strict law, and that the forms and words he uses all have a history and a reason for being what they are. In this way his intelligence as well as his memory will be excited and quickened, his curiosity, that "fountain-head of science," will be legitimately aroused and satisfied, and above all the conception of law will be made familiar to him from the first beginning of his education. When the action of philological laws has been traced and illustrated in modern languages, it will be easy to pass on to the dead ones and show how they are but the earlier forms of living speech, past links in the great chain of unbroken development.

Before parting from Miss Otté, allusion must be made to the reformed spelling of Dano-Norwegian and Swedish, which she has adopted in her Manual, and of which she has given an interesting account in her Introduction. This reformed spelling is in the first instance due to Rask, the great Danish philologist, but it owes its present acceptance to the Stockholm Conference, called together in 1869 by the exertions of Prof. Daa, and to the Dano-Norwegian dictionary which was the result of it. The vicious spelling of the past has now been superseded by a consistent and fairly phonetic one, based upon a scientific alphabet. In this respect the Danes have set us an example which it would be well to follow. The "practical men" of Scandinavia have at last condescended to listen to the recommendations of those who study language scientifically, and the people consequently now possess an orthography which forms no hindrance to learning to read and write and throws no veil over the true nature of speech. Let the Englishman who uses Miss Otté's Manual try to put himself in the place of a Dane who wishes to learn English, and then consider whether he does all in his power to facilitate the acquisition of at all events one language by the foreigner.

A. H. SAYCE

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts. No notice is taken of anonymous communications.*

[*The Editor urgently requests correspondents to keep their letters as short as possible. The pressure on his space is so great that it is impossible otherwise to ensure the appearance even of communications containing interesting and novel facts.*]

The Spectrum of Brorsen's Comet

I AM much obliged to Mr. Christie for his answer to my question. There can remain no doubt that Brorsen's comet does not *now* give the same spectrum as, according to Huggins's observations, it did in 1868. The difference in position between the brightest lines in the two spectra of carbon is, it is true, very small, but if it were possible it would be a step gained to decide which of the two lines the brightest comet band coincides with, 5198·4 or 5165·5, since as far as experimental evidence goes at present one of these lines is due to carbon-vapour and the other to an oxide of carbon. I fear that Prof. Piazzi Symth's theory that the spectrum in question is caused by hydrocarbon must be rejected for experimental reasons which I will presently recapitulate. I have had no experience in comet-spectroscopy, not having access to any telescope of sufficient aperture, and I do not wish, therefore, to seem to make light of the achievement of Mr. Christie and Prof. Young; but if it were possible to adjust the occulting bar so as to *completely* hide (but only *just* hide) the least refrangible edge of the brightest comet-band, then I should imagine that, on flashing in the spectrum of the alcohol-tube, its band would be seen beyond the bar if the comet-spectrum be, as is most probable, that which I have called "Carbon No. I."

At present the observations at the Royal Observatory seem to point to a coincidence with the second spectrum, but it was the *first* which Prof. Young employed and which Prof. Huggins also employed. A reference to Prof. Huggins's account of his experiments shows that the comparison-spectrum was obtained by taking the electric spark in olefiant gas at the ordinary pressure; and he further observes (*Quart. Jour. Science*, April, 1869) that "the same spectrum is given by the spark in cyanogen."

The difference between the spark in olefiant gas and in olive oil, shown in Huggins's diagram, is simply one of detail—the separate lines being distinctly seen in the spectrum of the oil and not in that of the gas.

Prof. Piazzi Smyth's alcohol-tube seems to differ from Mr. Christie's in containing besides the lines of spectrum No. II. (if he will allow me to call it so) the green band seen in the blue base of a candle flame—that is the band beginning with 5165·5.

This, I believe, is always the case if the vapour be at a somewhat high pressure. A reference to the *Phil. Trans.* for 1865, or the *Phil. Mag.* for October, 1869, will show that the tubes with which Plücker worked contained lines of both spectra—and that he did not succeed in completely separating the two. But a tube containing pure carbonic oxide at a small pressure (one or two millimetres) shows no trace of this green band even "end-on."

I cannot accept Prof. Piazzi Smyth's theory that this green band and the remainder of the lines in spectrum No. I. are due to hydrocarbon, for the simple reason that they are obtained brilliantly from substances which do not contain hydrogen, viz., cyanogen, carbonic oxide, and sulphide of carbon.

There is no more magnificent spectrum than the "carbon spectrum No. I.," obtained by burning cyanogen and oxygen together at the nozzle of an oxyhydrogen blow-pipe.

I should like to refer Prof. Smyth for other arguments than my own and for experimental evidence to a paper to be found in the *Ann. Ch. Phys.* for 1865, t. 4, p. 305.

Giggleswick, May 27 WILLIAM MARSHALL WATTS

A Universal Catalogue

THE last April number of NATURE contains an article on a Universal Catalogue, which seems to be still under discussion.

So great a work, when undertaken, should to a certain extent be complete, so as not to necessitate the same thing having to be done fifty times. With a really universal catalogue of books and memoirs existing, it would be quite easy for each library to form its own catalogue in a much abbreviated form. For instance:—

Brewster, Optics. 1831. P. 2350, or

Hauy, Crist. et Propr. phys. Enclase. 1819. Min. 6430,

would be quite sufficient to stand for—

Brewster, Treatise on Optics. London, 1831. Catalogue of Physical Science Papers, 2350. and

Hauy, Mémoire sur la Cristallisation et sur les Propriétés physiques de l'Enclase, Paris, Mus. Hist. Nat. Mém. v. 1819, pp. 278-293. Catalogue of Mineralogical Papers, 6430.

So in the library catalogues no cross references and main titles would be necessary, and no double and treble lines for titles of books or memoirs, five or six words and two numbers being sufficient to characterise each publication, while now, there being no general catalogue, each library desiring to give its catalogue—an undertaking which is highly desirable—is obliged to spend disproportionate cost, time, and space for such a purpose.

But scientific workmen would also be much better served in this way, as may be shown by the following facts:—

Putting the whole number of titles in the British Museum catalogue at 3,750,000 (1,250,000 real ones, 2,500,000 cross references, &c.), they may be classed into old and modern works, the former 750,000, the latter 3,000,000. Now, putting the number of special branches which deserve and imperatively demand special catalogues of subjects—as mathematics, botany, statistics, &c., &c.—at 50, and supposing that old books extend even 15 to 20 branches each, every special branch is represented by $\frac{760000}{60} \cdot 20 = 300{,}000$ titles of old publications and $\frac{3000000}{60} =$ 60,000 of new ones.

So, one seeking for books of a single branch does not find

more than 360,000 titles among 3,750,000, filling, when printed alone, 4·32, or in round numbers, 5 volumes of the 45, while he must undergo the trouble of using all the 45, or of this work, $\frac{40}{45}$, *i.e.*, 89 per cent. is useless and annoying for him, and $\frac{5}{45}$, or 11 per cent. only is useful; the space needed for the catalogue is about 4 metres, 44 centimetres of which are useful, and 3m. 56cm. disturbing; and, last but not least, he pays 36*l.* instead of 4*l.*

But with all this superfluous work, still no complete catalogue is acquired, but a very deficient one; for of periodical journal articles there are about 3,000,000, separate works about 6,000,000 in a rough estimation, or together, 9,000,000, *i.e.* (no main titles or cross-references being herein comprised), about six times the number possessed by the British Museum library.

Supposing, in the same proportion as above, these 9 millions of publications to be accompanied by 12 millions of main titles, &c.; supposing, then, these 21 millions of entries to be composed of 4·2 millions of old and 16·8 millions of new ones, the publication of these could be effected as follows:—

The titles of old books, being used much seldomer than new ones, and belonging mostly to fifteen to twenty different branches, could form a special catalogue of fifty volumes, whose price would be 40*l.*; each great city might content itself with a single copy accessible to all men of science.

The remaining 16·8 millions of modern publication titles, divided into fifty branches, would give 360,000 entries for each of them, or *five volumes for 4l.*, so that even private libraries would be enabled to possess a complete catalogue of all modern publications of a single branch.

As to the construction of such catalogues, the following would perhaps be a practical method:—

At first a committee for the defining of branches and the limit between old and modern publications should be appointed, to which all greater libraries should send copies of their catalogue classifications; by means of these copies exact rules for the extent of branches and the method of working could be drawn up in six months.

This work done, a numerous catalogue committee should be formed, to which all greater library catalogues should be sent in copies; where such copies are wanting the library should be examined by members of the committee, using the thitherto ready part of the catalogues.

The periodical publications before 1800 and after 1873, should be registered in the same manner as those in the "Royal Society Catalogue," and then subdivided into single branches by the committee. In this way complete catalogues for great groups could be formed, care being taken not to restrict the limits of these too much in order to hasten the publication of the work. This publication would be the first and hardest step to a manageable index of literature.

During the next ten years after its publication the completion could be carried out by putting beside each title a short classification of its contents, not an extract—contained in a single word or phrase, like "electrostat." or "relat. age mortal.," for "electrostatics" or "relation between age and mortality," or a few single words when different matters are treated; these classifications, made simultaneously by different persons and compared, together with all corrections, could be printed about twelve years after the first catalogue, and form the final work, which at short intervals of five or ten years should be completed by appendices.

ARISTIDES BREZINA

Custos of the Imperial Mineralogical Museum, Vienna

Distribution of Mus rattus

I AM able to-day to complete my note in NATURE, vol. xx. p. 29, as to the exact habitat of the black rat in Thuringia. Prof. Liebe, of Gera, kindly wrote to me that it occurs in East Thuringia and the Voigtland in single elevated side-valleys of the rivers Weisse Elster and Roda, as well as in single lurking-places of the Frankenwald. Here it occurs in isolated forest-houses, in the valleys, in whole partly large villages, for instance, St. Gangloff. In this place for a long time past *Mus rattus* and *M. decumanus* have occurred together among each other, not one above the other, on different floors, as might be supposed, though *rattus* now and then rather prefers the upper floors, and the latter does not appear to be decreasing in number. In those villages about three specimens of *rattus* are always killed for one specimen of *decumanus*, the latter, apparently, being less numerous.

A. B. MEYER

Dresden, Royal Zoological Museum, May 20

Insect Galls Buds

I WAS much interested in Mr. A. Stephen Wilson's letter upon this subject (NATURE, vol. xx. p. 55). I must, however, demur to his statement that "all insect-galls are in reality leaf-buds or fruit-buds," as too sweeping to be accurate. I can hardly include in the above category the numerous galls which make their appearance on the growing leaves of trees, such, for example, as the oak-spangles (of *Neuroterus malpighii*) or the galls of the *Spathegaster baccarum*, *Andricus curvator*, &c., several of which may be placed on the veins of a single leaf. These examples cannot assuredly be classed as pathologically developed leaf or fruit *buds* only so far as woody growth usually takes place through buds. In a short paper I once read at the Linnean Society, an abstract of which appeared in NATURE during the early part of the year 1875, I drew attention to the fact that the growth of galls took place coincidently with the growth of the tissues in which they were placed; thus the development of the bud-galls of *Cynips kolleri*, *Teras terminalis*, and *Aphilothrix gemmæ*, is to be seen in the spring, summer, and early autumn, but not in winter time when the tree growth is arrested. My observations at that time led me to suppose that the currant galls of the oak and others of the same class only grow during the growth of the leaf to which they were attached.

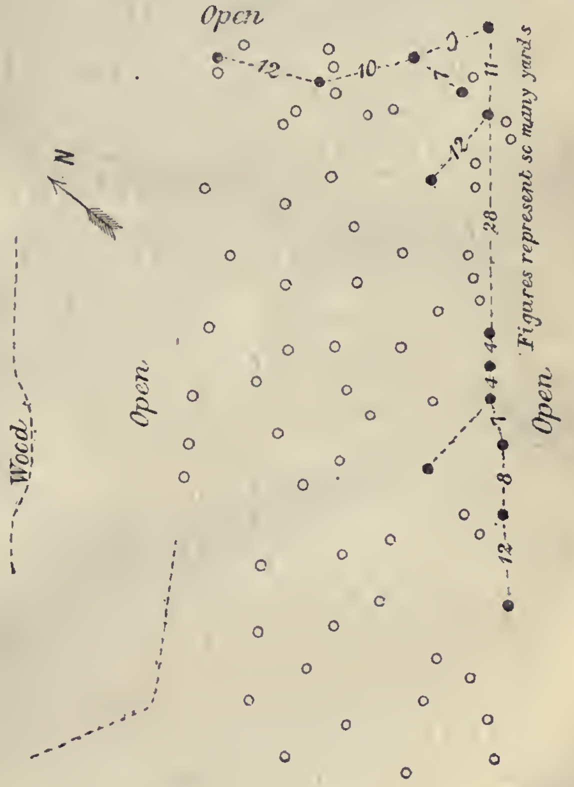
I trust Mr. Wilson will give your readers the benefit of his further researches on this subject.

W. AINSLIE HOLLIS

Brighton, May 16

Effects of Lightning

A REMARKABLE electric discharge occurred on Sir Robert Gordon's estate of Letterfourie in a small wood about four miles to the south-east of this place on November 16 last about 12.45 A.M. The accompanying sketch (scale $\frac{1}{24}''$ = one yard), where



the trees (common fir and larch) *struck* are represented by black dots, will give you an idea. The soil and trees were slightly covered with snow, which had been falling at intervals since sunset on the 15th. On that night I observed two or three flashes of lightning accompanied by thunder, and a few days afterwards

I was told by a local medical gentleman, who had visited the spot, that some eleven or twelve trees had been struck among the hills under peculiar circumstances. The snow was lying so deep at the time that the place was well nigh inaccessible, and owing to want of leisure and the continued severe weather, I had no opportunity of visiting the wood in question until a few days ago. I then ascertained from a farmer living 150 yards south-east of the spot, that the trees must have been struck simultaneously.

Between 9 and 10 P.M. on the 15th a flash of lightning, followed by loud thunder, was seen by him in the north and clear of the wood altogether; besides, the interval between flash and peal showed it to be at a comparatively great distance. The man, being an invalid, never slept, when about 12.45 A.M. on the 16th a blinding light immediately followed by a tremendous thunder-clap made him think his own house was struck. The next and last flash and peal occurred a quarter of an hour afterwards at a considerable distance away to the west.

The effect of the lightning on the trees was observed from the window on the following morning, and as the spot was daily visited by the inmates of the house for the purpose of drying clothes, there could be no doubt but the damage had been done during the previous night. All the fourteen trees, varying from six to nine inches in diameter, and not visibly higher than the immediately adjoining ones have lost the bark over a width of one half to one inch, and the wood is slightly split.

Buckie, Banff, N.B., May 12 G. W. CAMPHUIS

Intellect in Brutes

IN connection with recent correspondence in your columns, it has occurred to me that the following remarkable instance of reasoning in an animal might be of interest to your readers.

In 1877 I was absent from Madras for two months, and left in my quarters three cats, one of which, an English *tabby*, was a very gentle and affectionate creature. During my absence the quarters were occupied by two young gentlemen, who delighted in teasing and frightening the cats. About a week before my return, the English cat had kittens, which she carefully concealed behind book-shelves in the library. On the morning of my return I saw the cat, and petted her as usual, and then left the house for about an hour. On returning to dress I found that the kittens were located in a corner of my dressing-room, where previous broods had been deposited and nursed. On questioning the servant as to how they came there, he at once replied, "Sir, the old cat taking one, one in mouth brought them here." In other words, the mother had carried them one by one in her mouth from the library to the dressing-room, where they lay quite exposed. I do not think that I have heard of a more remarkable instance of reasoning and affectionate confidence in an animal, and I need hardly say that the latter manifestation gave me very great pleasure. The train of reasoning seems to have been as follows: "Now that my master has returned there is no risk of the kittens being injured by the two young savages in the house, so I will take them out for my protector to see and admire, and keep them in the corner in which all my former pets have been nursed in safety." G. BIDIE

Government Central Museum, Madras, May 3

GEOGRAPHICAL NOTES

THE anniversary meeting of the Royal Geographical Society was held on Monday last, Sir Rutherford Alcock, vice-president, in the chair. From the Council report it appears that there is no diminution in the number of Fellows, notwithstanding the losses from various causes. From a financial point of view, the Society continues to prosper, its assets being set down at over 37,000*l*., exclusive of its valuable map collection and library, both of which have received large accessions during the past year. It will be interesting to practical geographers to learn that considerable progress has been made with the revision of the classified register of maps and the preparation of an alphabetical catalogue of all the maps in the Society's collection and publications, and especially that the new catalogue is being prepared with a view to its being subsequently printed. We are also informed that a case containing a set of traveller's instruments, such as the Society recommend, has been placed in the map-room. At the conclusion of the report the royal medals were presented to Count Schouvaloff, the Russian ambassador (for Col. Prejevalsky), and General Sir Lintorn Simmons, R.E., G.C.B. (for Capt. W. J. Gill, R.E.), after which came the presentation of the Public Schools' Prize Medals, the award of which we have already recorded, and some interesting remarks on the teaching of geography, by the Rev. G. Butler, head-master of Liverpool College. The Hon. G. C. Brodrick announced the subject for next year's examination would be "Western Africa, from the Sahara to the Congo, and as far eastwards as Nyangwé." The Earl of Northbrook was elected president, and among the new members of council are General R. Strachey and General Sir H. L. Thuillier, late head of the great Trigonometrical Survey of India, both of whom are well known as scientific geographers. The Society being without a president, the annual address on the progress of geography was delivered by Mr. Clements R. Markham, the senior secretary. The chief items of news are that Lieut. R. C. Temple, of the 1st Gurkhas, has constructed a map of a large tract of previously unknown country between Candahar and Dehra Ghazi Khan, and has promised to furnish an account of the region, and that Mr. Whitely is about to attempt an examination of the mysterious Mount Roraima and its neighbourhood, in the interior of Guiana. In conclusion, Mr. Markham called attention to the short-comings of the Admiralty in the surveying department, expressing a hope that they might be induced to send out a properly equipped surveying-vessel to the southern part of the east and west coasts of Africa, "which have not been sounded since the days of Capt. Owen, half a century ago."

M. SOLEILLET, who recently tried to reach Timbuctoo, has arrived in Paris, and gave, on Monday, an address before the Société d'Études Maritimes et Coloniales, in the large hall of the Société d'Encouragement. M. Soleillet is in very good health, and no trace of his illness is now visible. He speaks highly of the negro population and the Sultan of Segou, where he spent more than three months as peaceably as in any French town, without any other escort than a single servant, a sergeant of the Senegal Rifles. The Niger at Segou-Sokkhora, more than 2,000 miles from its mouth, is about 300 yards wide. The access is very easy for traders. M. Soleillet will devote his future exploration to the determination of the best track for the trans-Saharan railway. He contrasted the good will of the negro population for the French with the hostility exhibited towards Europeans in the Sahara.

FROM *Globus* we learn that the long sojourn of the Russian troops in Bulgaria and Rumelia has been fruitful of results to geographical knowledge. The Russian staff have been active in carrying out a series of astronomical and geodetic observations, so that a fairly complete network of triangulation has been accomplished, which will enable cartographers to lay down with fair accuracy a very considerable number of places in our maps. Something like 1,000 points have been thus taken, most of them geodetically, but a considerable number astronomically. The chief results are expected to be published by 1880.

THE steamer *Nordenskjöld*, Capt. H. Sengstacke, formerly chief officer of the *Germania* on the second German Arctic expedition, sailed from Malmö, under the Russian flag, on May 12, for Behring Strait, *viâ* the Suez Canal. On board are Prof. Grigorieff of St. Petersburg, and Baron von Danckelman of Leipsic, to whom are intrusted the duties of zoologist and physicist respectively. The object in view, as our readers know, is to visit the mouth of the Lena, and, if necessary, render assistance to Prof. Nordenskjöld. The expedition is not

over-manned, as it consists but of sixteen persons, including officers, *savants*, two engineers, and three stokers. It is possible that by this time Nordenskjöld may have broken out of the ice and be on his way home by the Suez Canal. The letters received from him, referred to last week, are, Mr. Oscar Dickson informs us, dated February 8.

LETTERS from Prejevalsky, dated from Zaisan, March 20, inform us that the deep snows which cover the steppes had detained him there much longer than he had calculated. He was, however, to leave on March 21, and expected to reach Khami at the end of May, by way of the River Urunga and the southern spurs of the Altaï; unless prevented by excessive heat and want of water, he was to pursue his journey to the town of Shachjeou. Then he would attempt to ascend the two plateaux of Tibet; after ascending the second plateau he would have 1,000 versts of desert to make before reaching Lassa, from which he hopes to visit South-east Tibet.

A COMPLETE history of all North Polar Expeditions from the remotest ages down to the present day is about to be published by Cotta of Stuttgart. The title will be "Im ewigen Eis," the author is the popular writer, Herr Friedrich von Hellwald. Numerous illustrations, maps, and plans will enhance the value of the work, which will appear in thirty parts. The well-known explorer, Julius Payer, one of the commanders of the Austrian Polar Expedition in 1874, has accepted the dedication of the work.

FROM the *Colonies and India* we learn that a private telegram from Aden conveys intelligence of the arrival there on the 15th inst. of the British India Steam Navigation Company's steamer *Chinsura*, from Bombay, *en route* for Zanzibar, having on board four Indian elephants, the property of the King of the Belgians. These elephants will be employed for the purpose of ascertaining whether such animals can be made a means of transport in Africa.

THE Inter-Oceanic Canal Congress has been diligently carrying on its work in Paris for the last fortnight. It was divided into several sections, each to consider a special department of the subject. On Monday the Technical Section of the Congress met to hear reports from its two sub-committees, the second of which admitted the possibility of constructing a canal with locks by way of Nicaragua, while for a level canal it considered the course proposed by Lieutenants Wyse and Reclus to be the best, subject, however, to certain modifications. The first sub-committee presented estimates of the probable cost of the various routes.

OUR ASTRONOMICAL COLUMN

THE TOTAL SOLAR ECLIPSE OF MAY 22, 1724.—In the *Illustrated London News* of Saturday last are some quaint extracts from the newspapers of the time, relating to this eclipse, the last that was total in England. It may not be without interest to examine the general circumstances of this phenomenon, which we are now enabled to do with much precision, by taking advantage of the data furnished in Prof. Newcomb's recently published "Researches on the Motion of the Moon." The elements are as follow:—

G.M.T. of Conjunction in R.A., 1724, May 22, at 5h. 26m. 33s.

	°	′	″
Right Ascension	59	32	12·8
Moon's hourly motion in R.A.		38	21·1
Sun's " "		2	30·4
Moon's declination	21	5	7·4 N.
Sun's "	20	31	28·9 N.
Moon's hourly motion in declination ...		10	53·3 N.
Sun's " " " ...		0	29·0 N.
Moon's horizontal parallax		60	44·5
Sun's " "			8·7
Moon's true semi-diameter		16	33·1
Sun's " "		15	47·4

The sidereal time at Greenwich mean noon on May 22 was 4h. 1m. 3·6s., and the equation of time at conjunction in R.A. was 3m. 49·1s. additive to mean time.

Hence it appears that the central eclipse began at 3h. 41·6m. in long. 151° 39′ W., lat. 13° 55′ N.; it occurred with the sun on the meridian in long. 82° 36′ W., lat. 54° 30′ N., and ended in long. 11° 57′ E., lat. 45° 28′ N., or the sun set centrally eclipsed near Padua.

It was therefore late in the afternoon with the sun at small altitude that the eclipse was witnessed in these islands, and the following figures must very nearly define the course actually pursued by the moon's shadow:—

LONGITUDE.	N. Limit.	LATITUDE. Central Line.	S. Limit.
	° ′	° ′	° ′
4° W.	52 37	51 29·9	50 24
2° W.	51 57	50 49·5	49 43
0°	51 15	50 7·6	49 1
2° E.	50 32	49 24·4	48 18

The popular interest excited in this eclipse we may infer was mainly due to the publication of a chart of its track by Halley, then Astronomer-Royal. A copy of this chart is preserved at the apartments of the Royal Astronomical Society; it is entitled "A Description of the Passage of the Shadow of the Moon over Europe, as it may be expected May 11, 1724, in the Evening, by Edm. Halley, Ast. Reg." It was "Engraved and Sold by John Senex at the Globe against St. Dunstan's Church in Fleetstreet, Price 1*s*." Halley concludes some foot-notes as follows:—"At London we compute y^e^ Beginning at 5h. 40m. P.M., y^e^ Middle, when it will be nearly Total at 6.37, and y^e^ End 7.29. We wish our Astronomical Friends a clear Sky."

It will be borne in mind that the old style was still in use in this country in 1724, and the eclipse was thus dated May 11. Halley's predicted track is in very close accordance with that we have obtained above. His chart shows the central eclipse passing just south of Wexford, north of Bridgwater, over the Isle of Wight and south of Dieppe to near Venice; his northern limit of total phase passes just south of Dublin, over Leominster and Oxford, and Brentford near London, by Cambray and just north of Strasburg; the southern limit passes a little south of Kinsale, Padstow, Chartres, &c.

Dr. Stukeley observed the eclipse from Haradon Hill, near Amesbury, Wilts, and the account of it which he published in his *Itinerarium Curiosum* has been frequently transferred to our popular works. Assuming his position to have been in about 1° 47′ west of Greenwich, with a latitude of 51° 11′, we find by the above elements that totality would commence at 6h. 26m. 0s. local mean time, and continue 2m. 34s., the sun being at an altitude of 12°. The eclipse was central at or close to Ventnor, and was total there for 2m. 47s.; the newspaper of the time says, more than 1½ minute. Observations were made by Delisle and others at the Observatory of Paris, and by Maraldi and Cassini, at the Trianon, Versailles, "en presence du Roy." The calculated duration of totality at Paris is 2m. 23s., the middle at 6h. 49m. 41s. apparent time; Gaudin observed the duration 2m. 22s., and the middle at 6h. 50m. 2s.; other observers made the duration twenty seconds longer, which is certainly an error; at the Trianon it was observed to be 2m. 16s., a little less than the calculation makes it. The original observations of the French astronomers are given at p. 129 of Prof. Newcomb's work.

The next total eclipse of the sun visible in England will take place early on the morning of June 29, 1927, but totality will only continue some ten seconds.

THE MIGRATION OF BIRDS

IN a reply of Dr. Weismann's to some remarks by Prof. A. Newton in his paper on the migration of birds (NATURE, vol. xix. p. 579), a statement of mine is

quoted to the effect that "in July young starlings pass over Heligoland by hundreds of thousands *without a single old bird* accompanying them," the learned Doctor adding that he "cannot regard this as a *fact*, but as a more or less probable *conjecture*." This is a rather bold and unceremonious assertion. As, however, Dr. Weismann, with reference to the above, and to the autumnal passage of young birds prior to their parents in general, puts the question "*but are these really facts?*" admitting that if they were they would "seem to be against the sufficiency of the five senses"—and as in any probable future efforts of the learned gentleman's on the above topic, incontestable *facts* might prove infinitely more useful than ever so voluminous an amount of nicest *conjecture*, I beg to be allowed to contribute some statements bearing on the question, which are based on daily observations of mine now extending over a period of more than forty years, and made on Heligoland—than which an observatory more favoured for such purposes the rest of Europe may not afford.

Personal experience the learned Doctor does not seem to command respecting the migratory movements of birds, otherwise it might be supposed that he would have brought forward the results of his observations either in refutation of mine, or in confirmation of the same, and I cannot help adding that in my humble opinion, the treatment in whatever form of so grand and mysterious a phenomenon as the migration of birds, should be preceded by a study of the same in nature, if only it were in its simplest outward appearances. Such a proceeding would prevent the continual repetition of certain traditional errors, and of the building thereon of fallacious inferences and hypothetical assumptions.

But to return to the starlings in question. The learned Doctor maintains that I "could not possibly have inspected a hundredth part of these 'hundreds of thousands' of starlings flying about." Now, to a Heligolander, such a view of the question would, if anything, be most amusing. I fully uphold what I stated: all these birds touching Heligoland *are* inspected, and I may add that such is done by the most competent judges, who, in fact, think very lightly of distinguishing a young starling passing overhead from an old one.

When, in my correspondence with Prof. Newton, I drew his attention to the fact of the autumnal movement of young birds taking place from one to two months prior to that of their parents, I purposely referred to a species affording the most easy means for observations corroborative of my views, viz., the common starling. This bird is one of the very few species which perform their migratory flights at so moderate an altitude as to permit of the most satisfactory scrutiny of each individual of a whole flock. Besides such a scrutiny is greatly facilitated by the different colour of the old and young birds at the season in question; the former, on the wing or on the ground, appearing at any distance perfectly black, whilst the latter are of a very light brownish-grey colour, verging underneath on a soiled white; the entire appearance of both differing to such an extent that if a flight of these birds were passing overhead at a height from fifty to three hundred feet, consisting of even a thousand individuals, it would require but the most cursory glance forthwith to detect a single old bird among the whole number. That such appears so very incredible to Dr. Weismann only proves how very little practice he can have had in these matters.

Moreover, a very great proportion of these young starlings alight for some hours on the upper plateau of the rock, and furnishing, in contradistinction to the old tough birds, a rather dainty dish, they are pursued by the Heligolanders very eagerly, and shot in great numbers; the island taxidermist, Aeukeus, for instance, succeeding last summer in bagging *eighty-three* such young birds at the discharge of his two barrels. This latter incident alone may prove what quantities of these birds are captured here during the month of July of each succeeding year, and I repeat, they never contain the slightest admixture of old black specimens.

The above I suppose will be admitted as sufficiently *demonstrative facts*, and will I trust exculpate me from "building far-reaching theoretical inferences," a proceeding against which the learned doctor gravely says we must guard. May I be permitted to ask: to *whom* is this warning given? for hitherto I was rather given to believe that conjectures, theoretical inferences, and the like generally grow much more luxuriantly beneath the limited light of the study-lamp than in the face of free matter-of-fact nature.

Here may follow a few data respecting the periods of passage of the old and young starlings as noted down from daily observations, and I leave it to Dr. Weismann to admit the same as the documentary evidence of an "excellent ornithologist," as he so courteously terms me, or perhaps to dismiss them as of undemonstrated validity.

Sturnus vulgaris.—First week in June, 1878, some solitary old birds of extremely abraded plumage—supposed to be individuals that had lost their mates or were otherwise disturbed whilst breeding.

June 20 and 21, great flights of young birds; 22nd, 23rd, and 24th, enormous numbers of young birds; up to the end of the month thousands of young birds daily.

July 1 to 12, from a thousand to ten thousand young birds daily; 16th, many flights of hundreds; 25th, great many young birds.

Then follows a pause of two months during which no starlings whatever were seen, the migratory move being taken up again on September 22, when I find noted down:—

Starlings, old birds in fresh plumage, flights of many hundreds.

October 2 and 7, great many old birds; 8th, flights of thousands; 13th, Royston crows and old starlings by tens of thousands; 14th, crows many thousands, starlings hundreds of thousands; 15th, many; 16th, a few only; 20th, tens of thousands; 28th, great many.

November 18 and 19, flights from twenty to fifty.

December 9 to 18, flights from forty to sixty daily.

Thus I have witnessed the autumnal migration of the old and young starlings during the long series of years above stated. Invariably nothing but young grey birds pass over here (and in a broad front extending to both sides of the island) from the latter part of June to the end of July; then a pause ensues lasting from six weeks to two months, when during the latter part of September the movement is taken up again by the old birds in fresh black plumage, and continued to the close of November—by straggling parties oftentimes kept up till Christmas.

These are incontestable facts, however incredible they may appear to Dr. Weismann; but he may rest assured that not only all the young and old starlings passing over here *are* "*inspected*," but the many hundreds of thousands of miscellaneous birds visiting this island have to pass a very critical review in addition.

I cannot conclude these remarks respecting the question of young birds preceding during their first migratory trip their parents by one or two months, without stating that, so far as my long experience on Heligoland extends, there exists, among the 360 odd species collected here by myself, only one solitary exception to the general rule, viz., the cuckoo, *Cuculus canorus*, of which species the *old birds precede* their young by at least four weeks. Of all the rest, the young birds of the summer open the grand autumnal flight, *unaccompanied by any old*, the very finest old males at the close of the season bringing up the rear. In spring, however, *quite the reverse invariably takes place*, then the most perfect old males appear first, followed soon by old females, and later by younger birds of less perfect

appearance, in this instance the rear being brought up by the halt and lame: crippled birds that have lost a greater or less number of their wing or tail feathers, some toes, or even a whole foot.

All this is very strikingly exemplified here by the blackbird, for instance, with its varying dress according to age and sex, and this might with some attention be observed at other places also, though in the middle and south of England and Germany such observations become greatly more complicated, on account of the immigrants from the north mixing with such of the same species as have been breeding in these more southern latitudes, and where the grand opening migratory rush, as witnessed here in full original purity, has more or less relaxed in a *con amore* travelling by easy stages. H. GÄTKE

Heligoland, May 7

THE U.S. NATIONAL ACADEMY

ONE of the chief scientific events of the year in the United States is the annual meeting of the National Academy of Sciences, the most select scientific body in America, election to which is regarded as stamping a man as an acknowledged leader in science. This year the meeting took place at Washington from April 15 to 18, the acting president being Prof. O. C. Marsh, who opened the proceedings with a review of the Academy's official work during the previous year. He had to record the great loss sustained by the Academy in the death of its president, Prof. Joseph Henry, on May 13 last year. Henry had been president of the Academy for ten years. One of the principal functions of the Academy during the past year was the consideration of a plan for the reorganisation of the U.S. Surveys, to which we have already referred at length.

At the meeting of the Academy in April last year a resolution was adopted authorising the appointment of a committee to consider a plan proposed by Prof. Newcomb for determining the distance of the sun by measuring the velocity of light. In accordance with this vote, Prof. Marsh appointed as members of the committee, President F. A. P. Barnard, Professors Wolcott Gibbs, Henry Morton, George F. Barker, and E. C. Pickering. Their report was so favourable to the plan proposed that Prof. Marsh sent it to the Secretary of the Navy for transmission to Congress. An appropriation of 5,000 dols. for the required purpose was thus secured, and the work of constructing the necessary apparatus will be commenced as soon as the appropriation is available. The expenditure of the funds is entrusted to the Secretary of the Navy. It is hoped by those who proposed this plan that the experiments will lead to a more accurate determination of the distance of the sun than can be obtained by any other method known to astronomy.

Prof. William B. Rogers was elected President of the Academy, to fill the vacancy caused by the death of Prof. Henry. The election is a deserved tribute to Prof. Rogers, who has for half a century held a prominent place among American men of science. He was for many years a leader among American geologists in adopting the modern theories of evolution, and defended his views with rare eloquence as well as strong argument. During his connection with the Massachusetts Institute of Technology (1862–68), the health of Prof. Rogers became so much impaired that he was obliged to withdraw from all studious pursuits for a long period. His recovery of health was the occasion of hearty congratulation in 1875, when he was for a second time elected President of the American Association for the Advancement of Science. The new president is loved by everybody, is venerable with silver locks, and still retains the silver-tongued eloquence for which he used to be famous. But he is by no means rugged, and has to take care not to over-exert himself.

Many valuable papers were read during the meeting of the Academy, but our space will only permit of our referring to a few. We append a complete list, and those who desire a complete report of the Academy's proceedings will find it in *Science News* of May 1 and following numbers.

Two papers were presented by Mr. Peirce, entitled respectively, "On Ghosts in Diffraction Spectra" and "Comparison of Wave-Lengths with the Metre." It is well known to users of diffraction spectroscopes that ghosts of the lines appear in the images. Mr. Peirce has investigated this subject from a mathematical point of view, and he presented to the Academy a series of calculations based on the conditions which call forth these ghosts, and concluding with formulæ for determining their positions. In conjunction with Mr. Rutherfurd, Mr. Peirce has been investigating the relation of the wave-lengths of light to the metre. The object is to obtain a basis for measuring the standard metre. The metres that have been issued as standards change in length after a lapse of time. The German metre is said to differ from the French metre by one 25,000th. Mr. Peirce proceeded on the assumption that the wave-lengths of light are of a constant value. Certain questions have arisen in the course of this research. It was necessary to ascertain whether the spectral lines were fine enough to serve the purpose. There was a doubt as to whether the lines were displaced by "ghosts," and this led to the mathematical inquiry, previously alluded to, which has defined the position of ghosts relatively to the lines. Again, it was found needful that the spectrum to be observed should be at its maximum of brilliance. It had been noticed that two spectra composing a pair (that is, of the same order) are usually of different brightness, the right side spectrum differing from the left side one. This was specially true of spectra obtained from ruled glass; those from speculum metal were not so notably diverse in brightness. Examination showed that this characteristic was due to a difference in the sides of the groove ruled in glass. The diamond, in ploughing through the surface, raises a burr on the side of the furrow, and hence makes the two sides of the cut of unequal height. At first it was attempted to remove this imperfection by rubbing off the burr; but it was found that the material of the burr went to fill up the groove, and thus rendered the glass plate unserviceable. But, by first filling the groove with black-lead, then polishing off the burr, and finally removing the black-lead, plates were obtained that gave spectra of the utmost brilliancy, and the right and left spectra of each pair did not differ in brightness from each other. Mr. Peirce also gave the particulars of other improvements recently made in spectroscopic apparatus. One of these involved the construction of glass circles, and the work was so delicate that a well-known instrument maker had failed in four attempts. A method was described by which the accurate focussing of the heliostat—a matter of great importance—had been satisfactorily attained. The experimenters have succeeded in measuring a number of decimetre scales by centimetres. The probability of a single error is within the fiftieth part of a micron. (A micron is as much smaller than a millimetre as the latter is less than a metre.) Means have been devised which keep the apartment, where the experiments are made, at a fixed temperature, within one-tenth of a degree of Fahrenheit. With a sufficient number of observations, and the use of apparatus having their latest improvements, these experimenters hope to attain the object of their research, and limit the error to one-millionth part of a wave-length.

Prof. E. C. Pickering's paper on eclipses of Jupiter's satellites was one of considerable importance. He showed the value of the photometric method of observing these eclipses, and the valuable data that might be obtained by improvements in this method, both as to the sun's distance and as to Jupiter himself and his satellites.

In a paper on the winds on Mount Washington compared with the winds near the level of the sea, Prof. Elias Loomis came to the following conclusions:—1. In a majority of the cases where an area of low barometer passes over New England, attended by the usual circulating winds at the surface stations, this system of circulating winds does not extend to a height of 6,000 feet. 2. This system of circulating winds extends to the greatest height when the depression of the barometer is unusually great. 3. When, during the progress of an area of low pressure, a system of circulating winds reaches to the summit of Mount Washington, the change of wind to the east quarter usually begins at the surface stations eleven hours sooner than on the summit of the mountain; and the change back from east

to west usually begins five hours sooner at the base than at the summit.

Prof. Joseph Le Conte's paper on the extinct volcanoes about Lake Mono, and their relation to the glacial drift, was of much interest. The general form of the Sierra is that of a great wave, ready to break on its eastern side. It rises from the San Joaquin Plains by a gentle slope of fifty to sixty miles, reaches a crest 13,000 feet high, and then, in a space of five or six miles, plunges downward steeply to the plains of Mono, which are at an altitude of only 6,000 feet. In former periods, long, complicated glaciers, with many tributaries, occupied the western slope; on the east, comparatively short and simple glaciers came down in parallel streams, and stretched far out on the plain and into Lake Mono, which was then 700 feet above its present level, and of far greater extent than now, so that it washed the base of the Sierra. Icebergs from the glaciers floated on this inland sea and dropped *débris* on its bottom. Around the present lake is a nearly level desert plain, covered with volcanic sand, interspersed with fragments of pumice and obsidian, and overgrown with sage-brush (*Artemisia tridentata*). This plane is an old lake bottom; the volcanic ashes are a later deposit upon it. The desert is relieved by the Sierra walls, with deep cañons; by long parallel moraine ridges, stretching like arms from the mouth of each cañon, and bounding the pathways of ancient glaciers; by a cluster of recently extinct volcanic cones, fifteen or twenty in number; and, finally, by the bright waters and picturesque islands of the lake. The moraines average 300 to 406 feet in height, and five or six miles in length. Lake Mono is ten by fourteen miles in extent. Having no outlet, its waters are saline—essentially a strong solution of sodium carbonate, with smaller proportions of calcic carbonate, common salt, and borax. Four to six terraces are very distinct about Lake Mono. Some of these are traceable all the way around it; the highest is, according to Whitney, 680 feet. They are undoubtedly the remains of former lake-levels. The highest level would reach the moraines at the foot of the Sierra. Near the centre of the lake is a group of volcanic islands in a line with the group of volcanic cones on the plain to the southward. Steam and boiling water issue in many places in the rocky part of the island and in the shallow waters of that vicinity. The twenty or thirty volcanic cones on the plain vary in height from 200 to 2,700 feet above the plain. Some of them are probably recent, and retain a perfect form. Prof. Le Conte adduced evidence to show that the eruptions were—at least in part—more recent than the glaciers, and that many of the volcanoes themselves were also of later date than the Champlain epoch to which the glaciers are assigned. From his observations on Lake Mono, Prof. Le Conte concluded that its level is again rising, and that this had been going on for ten or fifteen years. He found near the margins of the lake, sheep-corral fences and old trails, submerged many feet. He also found dead sage-brush (*Artemesia tridentata*) and greasewood (*Sarcobatis vermiculatus*), that were under five feet of water. Neighbouring residents estimate the rise of the lake as ten to twelve feet in ten to fifteen years. The cause is evidently an increase of rainfall, and especially of snowfall. With regard to a moving snowfield, or rather an imperfect glacier, on Mount Lyell, Prof. Le Conte finds signs that the ice is advancing.

In a paper on vowel theories in the light of recent experiments with the phonograph, Prof. Graham Bell discussed the whole subject, and gives an account of his own recent experiences. Prof. Bell formulates his research as follows:—We may adopt the "fixed pitch theory," which supposes that the partial tones characteristic of vowel sounds have fixed, invariable pitches; and the element of pitch may be considered the distinguishing feature; or we may adopt the "harmonic theory," which assumes that the partial tones are harmonics of the fundamental, varying in pitch with it; the vowel characteristic lying in the predominance of certain harmonics. The fixed pitch theory finds much support from a consideration of the mechanism of speech. Various experiments, of which Prof. Bell exhibited a considerable number, tend to bias the mind in favour of this theory. But in a series of careful experiments with the phonautograph it was found that (1) Vowel sounds uniformly produced periodic curves, whatever pitch of voice was employed; (2) The form of vibration was not a stable phenomenon; (3) Different vowels, sung to different pitches, often produced sensibly similar curves; (4) Different vowels sung to the same pitch yielded curves of different shapes; but the differences were not so well marked as to identify the vowels; (5) The size of the aperture seemed to influence the complexity of the tracing. Prof. Bell tried a phonantograph made with the tympanic membrane of the human ear, but obtained no different results. The general indications of the phonautograph thus favour the harmonic hypothesis. The phonograph was finally tried to help in solving this problem. Other experimenters have tested the instrument on this point. After describing their experiments and results, Prof. Bell gave the details of his own. By changing the speed of the phonograph, such words as "mean, mane, men," were altered (approximately) to "moon, moan, morn," and the reproduced ee became a faint oo. Different opinions as to these sounds are entertained by others who have experiments of a similar character, but all of the numerous researches made on this subject confirm Prof. Bell in his view that the phonograph answers the question of vowel fixity in the negative. Some very recent experiments, made by Prof. Bell and Mr. Francis Blake, conjointly, not only demonstrate that the vowel quality changes under varying speed of the phonograph cylinder's rotation, but also show the direction and nature of the change. This was shown by starting the cylinder at a given velocity, and letting it slowly come to rest. During this reduction of speed the vowel-sound "ah" changed successively from "ah" to "awe," "oh," and "oo." (The same effect can be produced by gradually contracting and rounding the orifice of the lips, while, at the same time, the back of the tongue is slightly raised.) With decreasing rapidity of the cylinder, the prime tone and the partial tones fall simultaneously in pitch. If a gradually increasing velocity was employed, the vowel-sound "ah" gradually changed to that of "ir" in "sir," and then to that of "a" in the word "man." Meanwhile, the quality of the sound became metallic. These facts favour the fixed pitch theory. Prof. Bell approves the suggestion of Ellis, that "what we call our vowels are not individuals—scarcely species—but rather genera, existing roughly in a speaker's intention; but at present mainly constituted artificially by the habits of reading and writing. Of the two hypotheses it is certain that one (the harmonic) is wrong, and the other only partly right. Treating vowels as we find them—as genera of sounds instead of individuals—the most plausible theory seems to consist in what we may term the "Harmonic Fixed Pitch Theory," according to which a vowel is a musical compound composed of partial tones whose frequencies are multiples of the fundamental of the voice, the predominant partials being always those that are nearest in pitch to the resonance cavities formed in the mouth by the position of the vocal organs assumed during the utterance of the vowel. An interesting discussion followed the reading of this paper. Prof. A. M. Mayer remarked that it is exceedingly difficult to obtain uniformity of results in analysing vowel-sounds. One curious experiment made by Prof. Mayer consisted in covering the ears of a human subject with soft wax, so that they were hermetically sealed, and then applying to the top of the head an instrument which gave forth a certain note. The person thus treated heard the note one octave higher than it was actually sounded. On the whole, it must be admitted that we know very little of physiological acoustics.

The following is a list of the papers read at the meeting of the Academy:—

C. S. Peirce—On Ghosts in Diffraction Spectra; On Comparison of Wave-lengths with the Metre; On a Method of Swinging Pendulums, proposed by M. Faye; On the Errors of Pendulum Experiments; On Projections of the Sphere which still Preserve the Angles. S. H. Scudder—The Palæozoic Cockroaches. Henry Draper—Conformation, by Spectrum Photographs, of the Discovery of Oxygen in the Sun. S. Weir Mitchell—The Relation of Neuralgic Pains to Storms and the Earth's Magnetism. Joseph Le Conte—On the Extinct Volcanoes about Lake Mono, and their Relations to the Glacial Drift. E. D. Cope—On the Extinct Species of the Rhinoceros, and Allied Forms of North America. E. W. Hilgard—The Loess of the Mississippi and the Æolian Hypothesis. J. E. Hilgard—An Account of Geodetic Arcs determined by the Coast Survey in Relation to the Figure of the Earth; an Account of Recent Comparison of the British Imperial Standard with its Copies sent to the United States. J. E. Hilgard—Report of Progress of the International Bureau of Weights and Measures at Paris. G. K. Gilbert—On the Stability and Instability of Drainage Lines. E. C. Pickering—Eclipses of Jupiter's Satellites; two New Forms of Micrometer. C. V. Riley—The Hibernations and Migrations of *Aletia argillacea* (the parent of the cotton-worm). Alfred M. Mayer—Description and Exhibition of a

New Form of Heliostat. C. F. Chandler—A New Polariscopic Method for the Detection and Estimation of Dextro-glucose in the Presence of Cane Sugar and Inverted Sugar. A. Graham Bell—Vowel Theories considered in the Light of Recent Experiments with the Phonograph and the Phonautograph. Elias Loomis—The Winds on Mount Washington Compared with the Winds near the Level of the Sea. Henry L. Abbot—The Ignition of High Tension Fuses. Alexander Agassiz—Report on Dredgings in the Caribbean Sea by the Coast Survey Steamer *Blake*, Commander, John R. Bartlett, U.S.N. C. F. Chandler—On Two New Diazo Colours from Coal Tar. G. J. Brush—On a Mineral Locality in Fairfield County, Connecticut. H. A. Newton—On the Influence of Jupiter on Bodies passing near the Planet. J. S. Newberry—On the Great Silver Deposit recently Discovered in Colorado, Utah, and Nevada. Simon Newcomb—On the Recurrence of Solar Eclipses. F. A. P. Barnard—Report of the Committee on Weights, Measures, and Coinage.

NATIONAL WATER SUPPLY

THE Society of Arts has again done useful work in bringing together a jury of experts on the question of water supply; for though the subject has engaged public attention for nearly half a century, has been investigated by Royal Commissions, and inquired into by committees appointed by scientific societies, we still find ourselves face to face with so costly and cumbersome a system of legislature, that although the country receives a rainfall which has been amply demonstrated to be far in excess of all the requirements of human consumption, manufacturing interests and purposes of canalisation, we see large districts suffering all the ills due to a polluted water-supply, whilst in other areas excessive rainfall is passing to the sea in devastating floods.

It is obvious, from a consideration of this fact, that there exists but *one* remedy for this state of things—the creation of a central authority, with power over the whole water-rights of the country for all purposes whatsoever; and upon this point there is a most striking unanimity of opinion in all the speakers attending the Society of Arts conference this year and last. Whether this authority should be placed over the whole of the 215 river basins of England and Wales, or whether they should be subdivided into groups, each presided over by separate bodies, is a question of detail, and it is necessarily one which allows of a very large amount of difference of opinion, varying with the special knowledge and tendencies of the individual propounding the scheme.

Sir Henry Cole last year suggested a division into seven districts, each under a local commission, assisted by a well-known engineer, together forming a united board, for the discussion of general questions.

Mr. Shelford pointed out that 158 river basins are contained in one county, and might be presided over by county boards, while only eleven rivers are situated in four or more counties, for which he considers special legislation would be necessary. Mr. De Rance would divide the country into six groups of river basins, Mr. Conder into ten, and he suggested the formation of a board similar to the Hydraulic Works Department in Italy, who at once take charge of the area and population of each province, the altitude of the ground, the volume of the rivers, and the amount of rainfall.

To elicit information as to the best means of dividing the country into separate watershed areas, having regard to the wants of the population and the geological and hydrological conditions, the Society of Arts offered for competition, at the Congress just held, a gold and three silver medals. No paper, it appears, has been judged of sufficient value to entitle the author to the gold medal, but two, of the seven papers selected for printing, have been thought worthy of silver medals, contributed by Mr. F. Toplis and Mr. J. Lucas. The former proposes that the country should be mapped out into watershed districts of one or more river basins, governed individually by a body of commissioners, assisted by competent legal and engineering advisers, with charge over all rivers, and power to acquire all existing water-works and canals, acting under the direction of a Minister of Health.

Mr. Lucas divides the country into northern, midland, and southern districts, with the idea of giving the commissioner presiding over each area a similar disposition of mountains and plains and constituent geological strata.

Other authorities propose still other subdivisions, and we cannot but think that the legislative creation of a numerous body of commissioners, in various districts, each with varying requirements and conflicting vested interests, would for the present only tend to increase the existing confusion; for, as we stated last year, quoting Dr. Child, "the bane of all local government in England is the chaos of different and often conflicting authorities, existing each for a special purpose." It is difficult to see how this state of things would be improved by the large powers proposed to be given to a number of new local governing bodies. For ourselves we are more inclined to agree with Capt. Douglas Galton, that all existing information should be brought to one focus, and though this information lies scattered over many departments, the Local Government Board is the legitimate focus for it; and that whether or no it is considered necessary that a Minister of Health be appointed, the preliminary step which can at once be taken is to place the heads of departments who hold information in official relation with the Local Government Board. The departments he specially referred to, being the Geological Survey, the Ordnance Survey, the Register-General's Department, and the Rainfall Committee.

The maps of the Ordnance Survey that would be most useful for hydrological purposes are those on the scale of six inches to the mile, published for the six northern counties, part of Flintshire, and for the neighbourhood of London; but unfortunately for those who have recognised the practical value of the maps on this scale, for economic purposes, the Directors of the Ordnance Survey have given priority of appearance to the larger 25-inch maps, which in addition to the objection found to their use, from the small area they include, do not contain the contour lines of equal level, which give to every 6-inch map the usefulness of a model. The Ordnance Survey are, however, bringing out a new issue, brought up to date, of their 1-inch map of England and Wales, reduced from their 25-inch map; this new 1-inch map has no hill-shading, which so often obscured the topography of the older editions, but in its place contains the principal contour lines. This map will form an admirable basis for tracing the watersheds and other hydrological purposes for which the published Ordnance Survey Catchment Basin Map is far too small.

The information collected by the Geological Survey, consists of geological maps of a large region on the scale of one inch to the mile, and of maps on the six-inch scale in the northern counties, coloured for the geological formation, and "stippled" for the superficial clays and sands with which they may be overlaid; sections across country on the six-inch scale, showing the thickness of the various permeable and impermeable formations; memoirs descriptive of districts, and including the more minute details of the strata, and particulars of the well-sections. On the latter head we would specially allude to the exhaustive detail of wells, given in the memoir of the London basin, by Mr. Whittaker, which has furnished so practical a basis for the useful investigations of Mr. Lucas, who has added to them, from personal examination, the level of the underground water in the metropolitan area.

From information supplied by Mr. De Rance to the conference, it appears that the *pervious* water-bearing formations occupy about 22,000 square miles, absorbing on an

average about ten inches of rainfall a year, which, if all yielded up to wells, would give a daily average supply of 400,000 gallons per square mile, and he further shows that the larger area of these permeable formations lies east of the great water-shed, dividing England diagonally, and separating the Severn and Trent basins on the one side, from those of the Thames, east coast streams, Witham and Ouse on the other, the only important previous formation west of this boundary being the permian and new red sandstones. The latter occupies an area of 3,190 square miles.

This different disposition of the permeable and impermeable strata in England, at once explains how it is that the dry-weather flow of rivers like the Thames, draining a basin largely consisting of permeable strata, differs so remarkably in volume from rivers like the Severn, mainly occupied by impermeable silurian rocks and triassic marls, and the necessity is at once apparent of there being a *central authority*, taking cognisance of all matters bearing on water questions, and assisting parliament in giving or withholding to any corporation or district the water rights of any area to which they may lay claim. Thus, in the case of Liverpool, it is proposed to take from the sources of the Severn, a quantity of not less than 52,000,000 gallons a day, while Mr. Hawksley, in evidence before the Royal Rivers Commission, gives the driest weather flow, so low down the Severn as Tewkesbury, as only 90,000,000 gallons per day. With a margin so small, it is obvious that the maintaining of a sufficient volume of water for navigation, fisheries, and other purposes, is of national importance, and should be the subject of imperial care.

The basis of all calculations of the body of water available for gravitation purposes must of necessity be an accurate record over numerous localities of the amount of *rainfall*, and it is a matter of regret that the work carried out by Mr. G. T. Symons is not incorporated with the Meteorological Department of the Government. In 1865 the British Association appointed a Committee to assist Mr. Symons in developing the system of registration; the total number of stations now at work exceed 2,000, and the correspondence with these observers, the verification of their instruments and codification of their observations necessarily incur a large amount of expenditure. The British Association, after many years' support of the work, feeling it their duty rather to initiate than permanently subsidise investigations, have at length discontinued their grant, and the only sources with which this work of national importance to the country can be carried out by Mr. Symons are voluntary subscriptions and the profits on the annual sale of the volume of "British Rainfall." We trust that one result of the Congress may be to place this work on a more permanent and satisfactory basis, and also that the Ordnance or Geological Survey be charged with the gauging of the chief streams of the country, so that data may be furnished for really estimating what amount of rainfall at *once* runs off in impermeable districts, and how much is absorbed in permeable districts, without which all calculations as to probable yield are to a great extent hypothetical.

It is the fashion in some quarters to abuse the Local Government Board, but when it is realised that they have no authority given them by legislation to survey the country, seek out abuses, suggest and compel improvements,—until they are called to inspect often by the authorities who have allowed abuses to devastate a particular district,—we think that those who read their annual report of work will give them the greatest credit for the industry and ability with which, often at much personal discomfort, they track not only the fever-germs to their source, but confront the ignoranc and obstinacy of the small local authorities. We hoepe that the action of the Society of Arts, in bringing these matters prominently before the country may lead to the scope of the Local Government Board being so enlarged, their staff increased, and their sources of information widened, that they may become a Department of Health, ever ready not merely to find out the cause of disease, but to prevent the possibility of its occurrence. Towards this end, in rousing public opinion to the exigencies of the question, these congresses cannot be, perhaps, too highly valued. Already out of the congress held this year, a National Water Supply Exhibition has been inaugurated at the Royal Aquarium, which cannot but tend to popularise the subject, and if it should be possible to find the Exhibition a permanent home, at the South Kensington Museum, it would add an important factor to the already high educational value of that institution. Should a wider knowledge of these subjects become general, and the government legislate in the direction suggested by the Society, it will be felt that its President, the Prince of Wales, in first bringing the subject prominently before the Society, and in lately placing it before the Premier, will have been instrumental in bringing about the once almost Utopian hope of Charles Dickens, in his preface to the Pickwick Papers, that the time will come when "a few petty boards and bodies—less than drops in the great ocean of humanity which roars around them—are not for ever to loose fever and consumption on God's creatures, at their will, or always to keep their jobbing little fiddles going for a Dance of Death."

THE AUDIOMETER

ALREADY have experiments of the greatest practical value been made with the wonderful invention of Prof. Hughes described in our last number. Dr. B. W. Richardson has been applying it in two ways: as an Audiometer for the measurement of hearing, and a Sphygmophone for measuring the pulse. Both applications were described at the last meeting of the Royal Society.

The audiometer, as it had been used, was shown to the Society. It consists of two Leclanché's cells for the battery, a new and simple microphonic key connected with the cells and with two fixed primary coils, and a secondary or induction coil, the terminals of which are attached to a telephone. The induction coil moves on a bar between the two fixed coils, and the bar is graduated into 200 parts, by which the readings of sound are taken. The graduated scale is divided into 20 centims., and each of these parts is subdivided into 10, so that the hearing may be tested from the maximum of 200 units to 0°—zero. The fixed coil on the right hand contains 6 metres of wire; the fixed coil on the left hand contains 100 metres. By this means a long scale from the left hand coil is produced. The secondary coil contains 100 metres of wire.

In using the instrument, the induction coil is moved along the scale from or towards the larger primary, as may be required, and the degrees or units of sound are read from the figures on the scale, the sound being made by the movement of the microphonic key between the battery and the primary coils.

The instrument may be considered to afford the most satisfactory means for testing the hearing power of all persons who can define a sound. The range of sound is sufficient at the maximum—200°—for every one who is not absolutely deaf; 0°, or zero, is a point of positive silence from the instrument, or rather from the sound which it produces through the telephone.

One of the first facts learned with the audiometer is the suddenness with which the sound is lost to those who are listening. The sound is abruptly lost within a range of 2°; that is, within one-hundredth part of the entire scale. This is the case with those who are very deaf as well as with those who hear readily.

In testing the capacity of hearing, it is noticeable that the power to detect the diminishing sound is maintained best by continuing the reduction in trace or line while the attention is fixed. A sudden break may cause the sound to be lost to the listener long before his real incapacity to hear is reached. If, for instance, the sound be very faintly heard at 15°, and the induction coil be suddenly moved to 5°, the sound at 5° may be quite inaudible; but if the coil be slowly moved, unit by unit, from 15° to 5°, the sound at 5° may be distinctly heard.

The effect of filling the chest and holding the breath makes a difference in listeners. The capacity for hearing is for a few seconds increased by holding the breath. Holding the breath with the chest not full fails to produce the same result.

As a rule, the hearing of persons who are right-handed is most refined in the right ear, and as most persons are right-handed, it is found that the right ear is the best ear. This rule is, however, attended with many exceptions, since, for various reasons, some persons who use the right hand exclusively, practise for some particular purpose the use of the left ear, upon which that ear becomes more acute. Another point of interest attaching to this observation is, that the practice of using one ear for special refinement of the sense seems for the time slightly to impair the other ear, although there is no physical evidence of such impairment.

Connected with the last-named fact is another, namely, that by this instrument the deaf are found to fail in capacity of hearing not only by reason of physical defect, but also by failure of memory of sounds. Thus in a youth who had suffered serious defect of hearing for seven years, owing to partial destruction of the tympanum, and who in the right ear could only detect sound at 107°, there was an inability to catch all the sound lying between 130° and 107°, until he could remember what he had to listen for. By practising him then to detect the lowest sound that he was physically capable of receiving, Dr. Richardson got him to detect this one sound more readily than those which came higher up. By further practice all the intervening sounds became audible with equal facility.

By use of the audiometer the influence of atmospheric pressure on hearing is detectable. In Dr. Richardson's own case, when the barometer is at 30° he can hear on both sides close down to zero; but below 30° he fails by 2° on the left side to reach zero. In another person a similar failure extends to a loss of 4°.

Dr. Richardson has tried to determine in some of the lower animals whether there is the same sense of hearing as in man. In two dogs, one a terrier, the other a field spaniel, the range of hearing power seemed to be distinctly lower than it is in the human subject who has perfect hearing. In both these animals, which were healthy, and in the prime of life, the first indication of the detection of sound commenced at 10° on the scale.

Dr. Richardson's practical conclusions are—

1. The audiometer will, he thinks, be an essential in all physical examinations of men who are undergoing examination as to their fitness for special services requiring perfect hearing, such as soldiers, sentries, railway officials, and the like. 2. The instrument will be of great use to the physician in determining the value of hearing in those who are deaf, and in determining the relative values of the two organs of hearing. 3. In other forms of diagnosis he has found the instrument useful, as in anæmia and vertigo. 4. The instrument may be used to differentiate between deafness through the external ear and deafness from closure of the Eustachian tube—throat deafness. 5. The instrument promises to be very useful in detecting the effects in the body of those agents which quicken or excite the circulation, such as alcohol and other similar chemical substances. 6. The instrument promises to be of great service in determining the value of artificial tympanums in instances of deafness due to imperfection or destruction of the natural tympanum. Dr. Richardson finds in fine gold the substance for making the most useful and effective artificial drum.

The sphygmophone, for obtaining a secondary or telephonic sound from the movements of the pulse at the wrist, is devised by adding a microphone to a Pond's sphygmograph. Dr. Richardson mounts on a slip of talc, glass, or wood a thin plate of platinum or gas carbon. He places the slip in the sphygmograph as if about to take a tracing of the pulse. One terminal from a Leclanche's cell is connected to the platinum or carbon, and the second terminal from the cell to a terminal of the telephone, the other terminal of the telephone with the metal rod of the sphygmograph which supports the slip. The instrument is placed on the pulse, in the ordinary way, and is adjusted, with the writing needle thrown back, until a good pulsating movement of the needle is secured. The needle, in passing over the metallic plate, causes a distinct series of sounds from the telephone, which correspond with the movements of the pulse. The sounds are singular, as resembling the two words, "bother it." The sounds can be made very loud by increasing the battery power.

In this connection we may state that in the last number of *La Nature* a micro-telephonic explorer is described, also evidently of great use in pathology. This is a simple instrument, devised by MM. Charden and Prayer, consisting of a telephonic apparatus with microphonic intermediary to intensify any sounds sought for, and which, among other purposes, will be of great service in detecting any foreign body in a vital organ. The apparatus is quite portable and worked with comparative ease, though doubtless actual practice will suggest improvements both in this and in the applications devised by Dr. Richardson.

A MACHINE FOR DRAWING COMPOUND HARMONIC CURVES[1]

HARMONIC curves possess great importance, since they represent to the eye the circumstances of motion of bodies in a state of vibration, and hence apply not merely to the pendulum and to musical instruments when giving their tones, but also to the particles of air during the transmission of sound.

The study of these curves offers us two problems of almost equal importance and interest, viz.: First, Given the curve; required, to find its component simple elements. Second, Given the component simple curves; required, to construct the resulting compound curve. From the standpoint of acoustics these problems may be stated thus: First, Given a complex sound, required to find the simple musical tones of which it is composed. Second, Given the intensity, pitch, and phase of each of a number of pure musical tones; required, to find the effect of their simultaneous action on the air.

The laborious investigations of Donders, Helmholtz, and others into the constitution of the simplest elements of speech—the vowel sounds—show that the actual analysis of the simplest articulate sound is no easy matter. When the curve corresponding to the sound is once obtained, Fourier's theorem enables us to subject it to mathematical analysis, and thus determine by a somewhat laborious process, its simple harmonic elements. Three methods give us such curves. König[2] employed two tuning-forks, to actually draw the curve belonging to their combination; this method is limited to combination of two simple tones. Messrs. Jenkin and Ewing[3] magnified the impression made on the tin-foil of the *phonograph*, obtaining thus the curve belonging to the sound impressed on the vibrating disk.

[2] *Poggendorff's Annalen*, Bd. clvii. S. 177, 1876.

[3] NATURE, May 9, 1878: July 25, 1878.

A third method[1] is the photographing of the vibrations of a disk set in vibration by the sound to be analysed. The curves are drawn with great sharpness and seem to offer the best means for pursuing this investigation. It was the study of these photographs which led Prof. Blake to consult with Prof. H. A. Newton, of Yale College, on the possibility of producing similar curves by mechanical means. Prof. Donkin, F.R.S., had described a machine by which the combination of any *two* simple tones could be drawn,[2] but the apparatus was not available for more complex combinations. The machine now to be described was the result of this consultation.

Fig. 1 represents the machine. A, A^{i}, A^{ii}, A^{iii}, A^{iv}, A^{v}, are T-shaped pieces of sheet brass, sliding between screws, motion being given to each by a crank-pin entering a slot cut in the cross-bar of the T. Each crank is driven by a pulley which is set in revolution by a string passing completely around it. The wheel B serves to return the string to the tightening pulley, D, which gives or takes up the "slack" when the crank-pulleys are changed. Firmly attached to B, and revolving on the same axle, is a smaller wheel which drives the roller feeding the paper on which the curves are traced. To secure the necessary tightening of the second string, the axle of B is inserted in the end of a wooden bar which slides horizontally under the frame. The strain given by D having tightened the string sufficiently, this bar is clamped by the thumb-nut, F.

The driving roller, G, is covered with sand-paper, and the pressure of the companion roller, H, secures the feed of the paper between them. A small brass wheel, C, is pressed by the spring of its steel axle on the middle of the paper strip. It has a sharp edge, and prevents lateral motion of the paper liable to result from friction of the pencils.

E, E^{i}, E^{ii},, are strips of brass sliding between screws. Each has a steel spring attached to it, to the end of which a thick piece of brass is soldered. A hole through this brass is tapped with a screw thread, into which the pencils (or tubular pens) fit and are readily adjusted to the desired height. E, E^{i}, and E^{ii}, have each a steel pin projecting upward from their middle points. Similar pins project from points near the ends of A, A^{i}, A^{ii}, &c.

A cross-bar connects the pins A^{i}, E^{ii}, and A^{ii}, the joint at E^{ii} admitting simply of revolution, while at A^{i} and A^{ii} there are slots in the bar permitting both rotation and sliding. A^{iii}, A^{iv}, and E, are similarly connected. A third cross-bar connects E and E^{ii} with E^{i}, having slots at E and E^{ii}, and a simple rotary joint at E^{i}.

A is not represented as in action, in order not to complicate the drawing and description unnecessarily. It would be connected by a cross-bar with E^{i}, and a fourth slider (E^{iii}) placed midway between A and E^{i}.

The operation is as follows:—Imagine a strip of paper fed between the rollers and passing under the pencils. The pulleys revolve by the action of the string, and their cranks give the respective T's movements which are the rectilinear components of the circular movements of the crank-pins. A pencil attached *directly* to any one of the T-s, would therefore draw on the paper a simple harmonic curve,[3] whose "period" depends on the diameter of the pulley, and whose amplitude depends on the length of the crank-arm. The connection of the cross-bars with E and E^{ii}, compels these strips to perform movements which are respectively *one-half* those of $A^{iv} + A^{iii}$, and $A^{ii} + A^{i}$. Hence, from the pencil in E, we get a curve combining A^{iv} and A^{iii}, but having ordinates of one-half their sum; from the pencil in E^{ii}, a curve combining A^{ii} and A^{i}, in like manner. Finally, the cross-bar connecting E and E^{ii} determines a movement of E^{i} which is *one-fourth* the sum of the movements of the four T-s, and, therefore, E^{i} describes upon the paper the curve belonging to the chosen relations of "period," "amplitude," and "phase."

The relations of these three terms may be varied to any extent (within practical limits), and with great ease. The accuracy with which a definite period may be obtained without the use of gearing, is quite surprising.

Specimens of the curves obtained are given in Fig. 2.

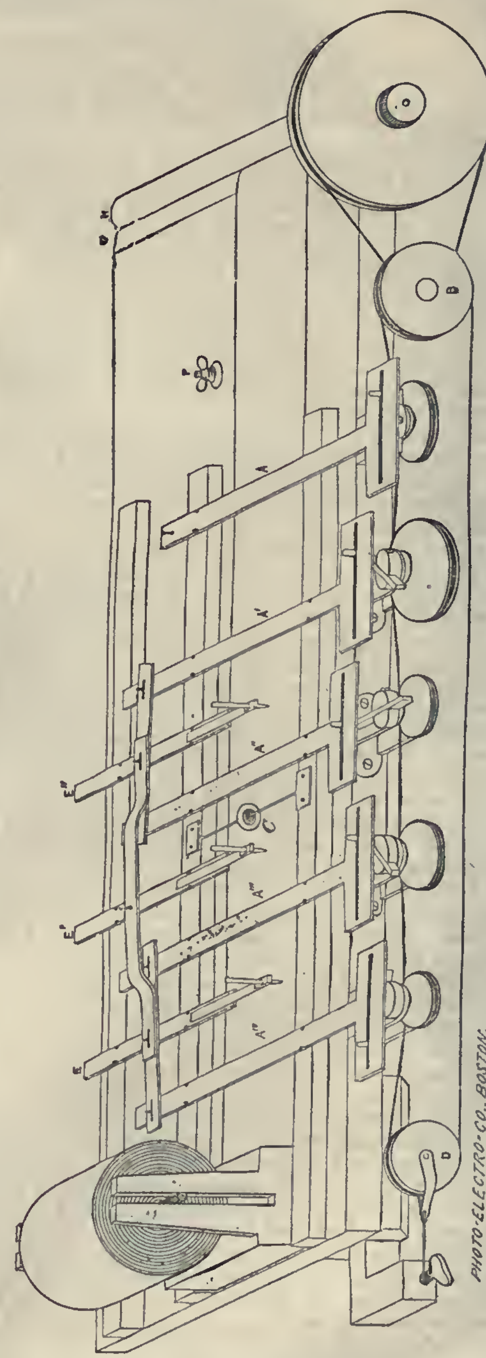

Fig. 1.

Nos. 1 to 8 (inclusive) are combinations of the first four terms of the Harmonic Series:—

Ratios of vibration	1 : 2 : 3 : 4.
Amplitudes of vibration	1 ½ ⅓ ¼.

Nos. 19 and 20 are combinations from the Diatonic Scale.
No. 19 shows the Common Chord, *Major*:—

Ratios of vibration ... ... 1 : $\frac{5}{4}$: $\frac{3}{2}$.

No. 20 shows the Common Chord, *Minor*:—

Ratio of vibration ... ... 1 : $\frac{6}{5}$: $\frac{3}{2}$.

In both the intensities of the component tones are equal, and their phases at starting identical.

BIOLOGICAL NOTES

Museum Pests in Entomological Collections.—Every record of successful contests with destroying agencies in museums will be of interest to collectors, and useful hints as well as valuable data in natural history may be derived from accounts of the animal species which appear in museums in widely separated localities. Very little information is as yet in print concerning museum pests in America, and Dr. H. A. Hagen has rendered a service to science by relating his experiences in the entomological collection of the Museum of Comparative Zoology, Cambridge, U.S. (*Proc.* Boston Soc. Nat. Hist., 1878, p. 56). He found *Dermestes lardarius* very abundant at first, but as it was easily recognisable it was soon extirpated. The excrements of the larva are large, granulous, and jet black. A much more dangerous foe is the larva of *Attagenus megatoma* (family Dermestidæ), having small globular ochreous excrements. Dr. Hagen was always able to find the crack in the box, through which the very thin and slender young larva entered. Anthrenus (same family) is represented by three species, of which the commonest in Europe (*A. museorum*) is very rare in Cambridge. *A. varius*, rare in Europe, is the most common pest in the collection, especially in new additions. *A. scrophulariæ*, the "carpet bug," has only been known to Dr. Hagen since 1872 in New England, and later still as a museum pest. It has since become very abundant and dangerous. The excrements consist of very fine light brown globules. *Ptinus fur*, so common in Europe, very seldom attacks the insects at Cambridge. *Tribolium ferrugineum* was imported from the East Indies. The flat body of the larva, as well as of the beetle, made it particularly fit to enter boxes through the smallest crack. It was got under by the aid of tobacco-smoke. The common clothes-moth was found very dangerous, and taught Dr. Hagen the lesson of placing every spreading-board at once in a tightly-closing box. Several years ago Dr. Hagen inclosed some clothes-moths with rotten insects in a glass-stoppered bottle, where they propagated year after year. In the fourth year the moths were noticed to be visibly smaller, and in the sixth most of them were scarcely half the ordinary size. But among them were always one or two of the normal stature. Nothing had been added to their food in these years. Two injurious species of Psocus, which are much attracted by paste and glue, do not infest Dr. Hagen's boxes, which are not lined with paper. Further, every spreading-board is carefully cleaned, and the cracks washed with alcohol before use. Acari have been easily kept out. Dr. Hagen strongly urges the entire separation of entomological rooms from those containing other preserved animals, especially mammals, birds, and skeletons. Having well-closing boxes, and never putting anything into the collection before it is safe, are the only satisfactory precautions. All other recommendations are but a poor substitute for bad boxes.

Effect of Light on Pelomyxa.—In a very low, amœba-like organism, *Pelomyxa palustris*, Herr Engelmann recently observed a remarkable action from sudden incidence of a moderate light (Pflüger's *Archiv für Physiologie*, Bd. xix. p. 1). Watched in the microscope this organism showed very slow movements, which, however, on shading the object, became much more lively. When the hand was removed, the granular mass in the interior became still, and the body contracted into a ball, as after an electric shock; this effect occurred within a few seconds. With continued moderate light, weak changes of form appeared again, with hardly perceptible locomotion. This experiment was several times repeated with equal success, and the results were especially notable in a dark room, into which diffuse daylight could be admitted. When, however, the room was illuminated, not suddenly, but gradually, the pelomyxa showed no effect.

The Ovule.—One of the most important of the recent contributions to the embryology of plants is, without question, Prof. Warming's memoir, "De l'Ovule" (*Annales des Scien. Nat.* sixe sér., Bot., tome v.). Commencing with a sketch of the views as to the origin of the ovule and nucleus, held in 1844 by Ad. Brongniart, which is in brief, "that there are two different origins for the ovule, the one to be found in the immense majority of flowering plants, in which the ovules make their appearance on the edges of the carpellary leaves, and represent the lobes or dentations of these leaves, the other confined to a very small number of plants (Primulaceæ, Myrsinaceæ, Theophrasteæ, and probably the Santalaceæ), in which the ovules correspond to so many distinct leaves carried on the prolongation of the floral axis. The nucleus is a production *de novo*, a cellular mamelon developed on the upper face of the lobe of the leaf and in the bottom of the cavity where it is formed." Cramer admits and confirms this view. Van Tieghem and Celâkovsky also agree to it, with this difference, that to them all the ovules appear as lobes of leaves, and that there are no independent ovular leaves. Warming, too, admits the theory. In every ovule there are, however, two parts essentially different, the funiculus and the teguments, which are, without doubt, of the nature of leaves, and the nucleus, which is a "new" creation—a veritable "sporangium," as Prantl says, a "sorus" composed of a single sporangium. Discarding for a moment the question whether ovular leaves exist or not (for example, in the yew), Warming doubts whether the funiculus should always be considered as foliar in certain cases. It is, perhaps, only a metablastome sprung from a leaf, but what is essential is that it is never a bud. In the memoir Warming looks at the question steadily from the point of view of histogenesis. The memoir consists of three chapters. On the early development of the leaf or ovular mamelon; on the genesis of the nucleus; and on the formation of the integuments of the mamelon. These chapters present a most masterly review of the whole question, one in which every due credit is given to the past and present workers in this field of research, and to none more than to the ingenious Slav botanist, Ladislao Celâkovsky. It is somewhat difficult to epitomise the author's conclusions, but he recognises that the morphological significance of an organ does not absolutely depend on its position. He demonstrates that the theory of Brongniart is the true and solely admissible one, and he reasons very conclusively against the views of Bronn, Eichler, and Strasburger, who would regard the ovule as a bud, while, in reality, as he says, "the ovule is the homologue of a sporangium."

Muscles of Crayfish.—While many observations of muscular contraction in vertebrate animals (especially the frog) are on record, the muscles of invertebrate animals have been little studied. M. Richet has recently directed his attention to these latter. From experiments with the myograph on the muscles of crayfish, he finds that the contraction of the muscle of a claw lasts nearly ten times as long as that of the caudal muscle (80 to 100 stimulations per second were needed to cause tetanus in the tail, while 2 to 4 sufficed for the claw). The contraction was not more retarded in one muscle than the other; with strong direct excitations, it is about a hundredth of a second; with weak it may be four or five hundredths. With the former stimulations applied to the ganglionic chain instead of directly, the total retardation is about 2·5 hundredths of a second. The muscle of the tail is very quickly exhausted, and this agrees with the fact that crayfish cannot swim any great distances. On the other hand, the muscle of a claw, stimulated by very closely following electric currents, is not exhausted. While the tetanus of the caudal muscle does not last more than twenty to thirty seconds, the muscle of the claw remains contracted nearly half an hour, and during the first five minutes the constriction of

the claw is stronger and stronger. This, too, accords with the habits of the crayfish, which will almost sooner die than let go its prey when seized. Thus between the two chief muscles of the crayfish there is a difference at least as considerable as between the striated and non-striated muscles of vertebrates.

SUSPENDED ANIMATION

THE statements in the *Times* of Monday, which, under the head of "A Wonderful Discovery," are copied from the *Brisbane Courier*, seem greatly to have astonished the reading public. To what extent the statements are true or untrue it is impossible to say. The whole may be a cleverly-written fiction, and certain of the words and names used seem, according to some readers, to suggest that view; but be this so or not, I wish to indicate that some part, at all events, of what is stated might be true, and is certainly within the range of possibility.

At once let me state that the discovery, so called, which is described in the communication under notice, is not in principle new. On the subject of suspension of animation I have myself been making experimental inquiries for twenty-five years at least, and have communicated to the scientific world many essays, lectures, and demonstrations relating to it. I have twice read papers bearing on this inquiry to the Royal Society, once to the British Association for the Advancement of Science, two or three times in my lectures on Experimental and Practical Medicine, and published one in NATURE. In respect to the particular point of the preservation of animal bodies for food, I dwelt on this topic in the lectures delivered before the Society of Arts in April and May of last year, 1878, explaining very definitely that the course of research in the direction of preservation must ultimately lead to a process by which we should keep the structures of animals in a form of suspended molecular life.

Let me next point out what, by experiment, is known as to the possibility of suspending animal life.

If an animal perfectly free from disease be subjected to the action of some chemical agents or physical agencies which have the property of reducing to the extremest limit the motor forces of the body, the muscular irritability, and the nervous stimulus to muscular action, and if the suspension of the muscular irritability and of the nervous excitation be made at once and equally, the body even of a warm-blooded animal may be brought down to a condition so closely resembling death, that the most careful examination may fail to detect any signs of life. I have shown in a Croonian lecture that there are three degrees of muscular irritability to which I have given the names of active efficient, passive efficient, and negative. The first of these states is represented in the ordinary living muscle in which the heart is working at full tension, and all parts of the body are thoroughly supplied with blood, with perfection of consciousness in waking hours, and, in a word, full life. The second of these states is represented in suspended animation, in which the heart is working regularly, but at low tension, supplying the muscles and other parts with sufficient blood to sustain the molecular life, but no more. The third of these states is represented when there is no motion whatever of blood through the body, as in an animal entirely frozen.

The second stage, the stage of passive efficiency, is that in which animation is usually suspended. The condition is a close semblance to the third stage, but differs from it in that under favouring circumstances the whole of the phenomena of the active efficient stage may be perfectly resumed, the heart suddenly enlarging in volume, from its filling with blood, and reanimating the whole organism by the force of its renewed stroke, in full tension.

So far as we have yet proceeded, the whole phenomena of restoration from death are accomplished during this stage. To those who are not accustomed to see them, they are no doubt very wonderful, looking like veritable restorations from death. They surprise even medical men the first time they are witnessed by them.

At the meeting of the British Medical Association at Leeds, a member of the Association was showing to a large audience the action of nitrous oxide gas, using a rabbit as the subject of his demonstration. The animal was removed from the narcotising chamber a little too late, for it had ceased to breathe, and it was placed on the table, to all appearances dead. At this stage I went to the table, and by use of a small pair of double-acting bellows restored respiration. In about four minutes there was revival of active irritability in the abdominal muscles, and two minutes later the animal leaped again into life, as if it had merely been asleep. There was nothing remarkable in the fact, but it excited, even in so cultivated an audience as was then present, the liveliest surprise.

The time during which an animal body may be capable of re-animation from the state of passive efficiency depends altogether on one circumstance, viz., whether the blood, the muscular fluid, and the nervous fluid remain, in a condition which I have defined in another essay as the aqueous condition, or whether these fluids have become pectous. If the fluids remain in the aqueous state, the period during which life may be restored is left undefined. It may be a very long period, including weeks, and possibly months, granting that decomposition of the tissues is not established, and even after a limited process of decomposition, there may be renewal of life in cold-blooded animals. But if pectous change begins in any one of the structures I have named, it extends like a crystallisation quickly through all the structures, and thereupon recovery is impossible, for the change in one of the parts is sufficient to prevent the restoration of all. Thus the heart may be beating, but the blood being pectous it beats in vain; or the heart may beat and the blood may flow, but the voluntary muscles being pectous, the beating is in vain; or the heart may beat, the blood may flow, and the muscles may remain in the aqueous condition, but the nerves being pectous the circulating action is in vain; or sometimes the heart may come to rest and the other parts may remain susceptible, but the motion of the heart and blood not being present to quicken them into activity, their life is in vain.

The problem physiologically before us is as follows:—Can the second or passive efficient stage of life be by any artificial methods secured, so that all the vital parts may be held in suspended animation, working at the lowest possible expenditure of vital power?

Experimental research and experience alike show the certain possibility of temporarily producing this state. Both show that there are agents and agencies by which life may be reduced to the low ebb necessary for suspension of active life, and at the same time the aqueous conditions of the colloidal fluids may be maintained. Cold is the first and most efficient of these agencies. The blood and the colloidal animal fluids derived from it are all held in the aqueous condition of colloidal matter by exposure to cold at freezing-point. At this same point all vital acts, excepting, perhaps, the motion of the heart, may be temporarily arrested in an animal, and then some animals may continue apparently dead for long intervals of time, and may yet return to life under conditions favourable to recovery.

In one of my lectures on death from cold, which I delivered in the winter session of 1867, some fish, which, during a hard frost, had been frozen in a tank at Newcastle-on-Tyne, were sent up to me by rail. They were produced in the completely frozen state at the lecture, and by careful thawing many of them were restored to perfect life. At my Croonian lecture on muscular irritability after systemic death, a similar fact was illustrated from frogs.

There seems in cold-blooded animals so circumstanced to be no recognisable limit of time after which they may not recover, but there is much skill required in promoting the recovery. If in thawing them the utmost care be not taken to thaw gradually, and at a temperature always below the natural living temperature of the animal, the fluids of the animal will pass from the frozen state through the aqueous into the pectous so rapidly that death from pectous change will be pronounced without perceiving any intermediate or life-stage at all. In warm-blooded animals it is extremely difficult to restore animation after suspension of life by cold, owing to the fact that in their more complex and differently-shielded organs, it is next to impossible to thaw equally and simultaneously all the colloidal fluids. In very young animals it can be done. Young kittens, a day or two old, that have been drowned in ice cold water, will recover after two hours' immersion almost to a certainty, if brought into a dry air at a temperature of 98° F. The gentlest motion of the body will be sufficient to re-start the respiration and therewith the life.

The nearest approach we see naturally to this state is in hybernating animals. In them the effects of cold in the season for hybernation and the recovery from the torpor are seen even in matured and old animals. In hybernation, however, there is not produced the complete stage of passive efficiency. There is in them a slow respiration and a low stage of active efficiency of circulation. The hybernating animal sleeps only; and while sleeping it consumes or wastes, and, if the cold be prolonged, it may die from wasting. From the sleep of hybernation also the animal can be roused by the common methods used for waking a sleeper, so that animation is not positively suspended.

Returning to the extreme effects of cold on animal bodies, it is hard to say whether an animal like a fish, frozen equally through all its structures, is actually dead, in the strict sense of the word, seeing that if it be uniformly and equally thawed it may recover from a perfect glacial state. In like manner it may be doubted whether a healthy warm-blooded animal, suddenly and equally frozen through all its parts, is dead, although it is not recoverable, because, in the very act of trying to restore it, some inequality in the direction is almost sure to determine a fatal issue owing to the transition of some vital centre into the pectous state of colloidal matter. I do not, consequently, see that cold can be of itself and alone utilized for maintaining suspended animation in the larger warm-blooded animals of full growth. At the same time cold will, for a long time, maintain, ready for motion, active organs locally subjected to it. Even after death this effect of it may be locally demonstrated, and has sometimes been so demonstrated to the wonder of the world. On January 17, in the year 1803, Aldini, the nephew of Galvani, created the greatest astonishment in London by a series of experiments which he conducted on a malefactor, twenty-six years old, named John Forster, who was executed at Newgate, and whose body, an hour after execution, was delivered over to Mr. Keate, Master of the College of Surgeons, for research. The body had been exposed for an hour to an atmosphere two degrees below freezing-point, and from that cause, though Aldini does not seem to have recognized the fact, the voluntary muscles retained their irritability to such a degree that when Aldini began to pass voltaic currents through the body some of the bystanders seem to have concluded that the unfortunate malefactor had come again to life. It is significant also that Aldini, in his report, says that his object was not to produce re-animation, but to obtain a practical knowledge how far galvanism might be employed as an auxiliary to revive persons who were accidently suffocated, as though he himself were in some doubt.

In repeating Aldini's experiments on lower animals that had passed into death under chloroform, with the view of determining what is the best treatment for those human beings who sink under chloroform and other anæsthetics, I failed altogether to obtain the same results when the temperature of the day was high. Noticing this, I experimented at or below freezing-point, and then found that both by the electrical discharge and by injection of water heated to 130° F. into the muscles through the arteries, active muscular movements could be produced in warm-blooded animals many hours after death. Thus, for lecture experiment I have removed one muscle from the body of an animal that had slept to death from chloroform, and, putting the muscle in a glass tube surrounded with ice and salt, I have kept it for several days in a condition for its making a final muscular contraction, and, by gently thawing it, have made it, in the act of final contraction, do some mechanical work, such as moving a long needle balanced on the face of a dial, or discharging a pistol.

In muscles so removed from the body and preserved ready for motion, there is, however, only one final act. For, as the blood and nervous supply are both cut off from it, there is nothing left in it but the reserve something that was fixed by the cold; but I do not see any reason why this should not be maintained in reservation for weeks or months, as easily as for days, in a fixed cold atmosphere.

Besides cold there are other agencies which hold the colloidal fluids in the aqueous state, and which, while they suspend the motor function, suspend without necessarily destroying life. Several agents of this class have been discovered.

Mandragora.—The first known of these suspending agents was mandragora. This was known as far back as Dioscorides. Dioscorides states that this vegetable substance may be administered in such a manner that the signs of active life may disappear, and sensibility be so far destroyed that the physician or surgeon may operate on the temporarily insensible without producing pain. The suspension of life from mandragora may extend over some hours, and the use of the agent probably was continued until the twelfth or thirteenth century. From the action of it doubtless comes the Shakespearian legend of Juliet. In modern times I have made the wine of mandragora, and found that it has the power originally attributed to it of suspending without destroying active life. The wine from it was the morion of the ancients, the fluid probably that was used by the Jewish women in the times of the Sanhedrim to destroy the sufferings of those who were under torture, and sometimes, perchance, to deceive the executioner and prevent the deadliness of his task.

The plant from which morion was originally made, the *Atropa belladonna* (deadly nightshade), has, in this country, similar properties to its ally the *Atropa mandragora.* In 1851 I attended at Mortlake two children who were poisoned for a time from eating the berries and chewing the leaves of the nightshade which they had gathered near to Richmond. The children were brought home insensible, and they lay in a condition of suspended life for seven hours, the greatest care being required to detect either the respiration or the movements of the heart. They nevertheless recovered.

Nitrite of Amyl.—In my original researches on the nitrite of amyl, one of the observations which most surprised me was the power of this agent to suspend animation. In the report I made to the British Association in 1864 on this subject, I showed that the life of the frog might be suspended for the period of nine days, and yet recovery to full and vigorous life might follow; that the same power of suspension, in a lesser degree, could be produced in warm-blooded animals, and that the heart of a warm-blooded animal would contract for the period of eighteen

hours after apparent death. The action of the nitrite of amyl in causing suspended animation seemed to be like cold. It prevented the pectous change of colloidal matter, and so prevented rigor mortis, coagulation of blood, and solidification of nervous centres and cords. So long as this change was suspended return of vital function was possible. When the pectous change occurred, all was over, and resolution into new forms of matter by putrefaction was the result.

From the analogy of some of these symptoms from nitrite of amyl with the symptoms of the disease called catalepsy, I have ventured to suggest that, under some abnormal conditions, the human body itself, in its own chemistry, may produce an agent which causes the suspended life observed during the cataleptic condition.

Woorali in a similar manner suspends vital function; but as the influence of this agent has been more frequently under observation from other physiologists, I leave it with this mention of it.

Chloral Hydrate has many of the properties of the other substances named above in its power of suspending life. At the meeting of the British Association at Exeter, at which I made the earliest report in this country of Liebreich's remarkable discoveries, some pigeons, which had been put to sleep by the needle-injection of a large dose of chloral, fell into such complete resemblance of death, that they passed among an audience containing many physiologists and other men of science for dead. For my own part I could detect no sign of life in them, and they were laid in one of the out-offices of the museum of the infirmary as dead. In this condition they were left late at night, but in the following morning they were found alive and as well as if nothing hurtful had happened to them.

Cyanogens. — Cyanogen gas and hydrocyanic acid, deadly poisons as they are, have the power in a singular degree of suspending animation. Combined with a sufficient degree of cold to prevent their evaporation from the body, their suspending power is of the most definite kind. In the laboratory of a large drug establishment a cat, by request of its owner, was killed, as it was assumed, instantaneously and painlessly by a large dose of Scheele's acid. The animal appeared to die without a pang, and presenting every appearance of death was laid in a sink to be removed on the next morning. At night the animal was lying still in form of death in the tank beneath a tap. In the morning it was found alive and well, but with the fur wet from the dropping of water from the tap. This fact was communicated to me by the eminent chemist under whose direct observation it occurred, in corroboration of an observation of mine similar in character.

Alcohol is another substance which holds the vital functions in suspense for long periods of time, the muscles retaining their excitability. In animals killed by alcohol in combination with cold, two influences which act powerfully together in the same direction, I found the muscular excitability could be retained at freezing-point for several hours even in birds. A remarkable similar experience, which I have elsewhere recorded, was obtained in the case of an intoxicated man who, while on the ice at the Welsh Harp lake, fell into the water through a breakage in the ice, and who for more than fifteen minutes was completely immersed. This man was extricated to all appearances dead, but under artificial respiration, carried out by my friend Dr. Belgrave, of Hendon, he was restored to consciousness and lived for several hours.

Oxygen.—It is not a little singular that pure oxygen gas possesses the power of suspending life, at all events in muscular fibre, when it is aided by condensation produced by cold; but I am on new ground here, with which I am not so conversant at present as I hope to be.

I have now shown as briefly as was possible that much is known in the world of science in respect to suspension of animal life by artificial means. It will be seen that cold as well as various chemical agents has this power; and it is worthy of note that cold, together with the agents named, is antiseptic, as though whatever suspended living action, suspended also by some necessity or correlative influence the process of putrefactive change. Hence the influence I drew in my lecture at the Society of Arts, that it was within the range of experiment to preserve the structures of dead animals in a form of suspended molecular life.

If the experiments reported from Brisbane be reliable it is clear, I think, that what has been done has been effected by the combination of one of the chemical agents above named, or of a similar agent, in combination with cold, the efficiency of which combination we have seen in many of the experimental facts referred to above. The only question that exists as of moment is, not whether a new principle has been developed, but whether, in matter of detail, a new product has been discovered which, better than any of the agents we already possess, destroys and suspends animation. In organic chemistry, there are, I doubt not, hundreds of substances which, like mandragora and nitrite of amyl, would suspend the vital process, and it may be that a new experimenter has met with such an agent. It is not incredible indeed that the Indian Fakirs possess a vegetable extract or essence which possesses the same power, and by means of which they perform their as yet unexplained feat of prolonged living burial: but I confess, on reading the Australian narrative, there is nothing suggested by it to my mind that might not be produced by agents already known. Making allowance for what is clearly a very enthusiastic description, there is nothing in an experiment related as made on a dog that might not have been produced by the subcutaneous injection of hydrate of chloral; neither is there anything in other experiments that might not follow from the injection of chloral or woorali in a cold atmosphere. At the same time it is not also unreasonable to infer that a new product has been found which surpasses any we possess, and suspends animation for a longer period. My faith is most shaken first by the statement that the agent referred to is a secret, for men of true science know no such word; secondly, that the experimenter has himself to go to America to procure more supplies of his agents; and thirdly, that he requires two agents, one of which is antidotal to the other. I can understand the production of a definite effect from a single; and others as well as myself have made out a great many facts respecting the antagonism of one agent by another. But in our researches on antagonistic physiological substances we require the agencies of absorption and circulation of the antidote, and how in a body bereft of motion and practically dead such absorption can take place I am unable to divine.

But even should the description given by the Australian journalist prove overdrawn or imaginative, I am not sorry it has appeared, since it has afforded a reason for relating in a plain and faithful manner to what actual extent human knowledge has been advanced by experiment on the subject under consideration. This duty, though it be but preliminary, is important as an introduction to those great events which in the future are sure to come from the positive results that have already been secured, and for which the world should be prepared, without anxiety or amazement.

BENJAMIN WARD RICHARDSON

NOTES

THE death is announced of William Froude, F.R.S., a name familiar to our readers in connection with experiments on wave-resistances and the form of ships. Mr. Froude, who had long

been in weak health, left England in November last year, in H.M.S. *Boadicea*, for a holiday cruise to the Cape, and he died from dysentery on the 4th inst., at Simon's Town. We defer further notice of Mr. Froude's life and work till next week.

ANOTHER advance of the greatest importance has been made by the U.S. Signal Service in the department of practical meteorology. In the *Daily Graphic* for May 9, published in the afternoon at New York, is a map of the principal portion of the United States, with the weather conditions of the same morning. The map gives in distinct outline the lines of equal atmospheric pressure and of the temperatures over the United States, with the prevailing directions of the wind and the general weather conditions. By the aid of this map, which it is proposed to make a regular feature of the *Graphic*, any one can form a fair idea of the weather changes in any specified locality for some days to come. The observations indicated in the map were made at all the signal stations of the U.S. Government at thirty-five minutes past seven on the morning of the 9th, and having been collated at the central office in Washington at nine o'clock, were transmitted specially by telegraph to the *Graphic* by ten o'clock. All the details of the map have been carefully considered and are easily intelligible to any reader after a little study. The importance of this step cannot be overrated, and we only wish we saw the *Pall Mall* and other evening papers following the excellent example of their New York contemporary.

PROF. ASAPH HALL has been elected a corresponding member by the Paris Academy of Science to fill the place in the astronomical section vacant by the death of M. Santini.

THERE is being erected at Meudon a large construction in connection with the Physical Observatory, where a large refracting telescope will be fitted up. During the time that the works are being carried on M. Janssen continues his solar photography on the site where his instruments have been established, in a part of the old Château. The diameter of the photographs obtained by direct operation is now 50 centimetres, and the time of exposure to solar radiation diminished to $\frac{1}{3000}$th of a second. The interval of time between two successive operations has been reduced to two minutes by the application of the revolver system. Although the two images may represent the surface of the sun at periods so near each other, M. Janssen has discovered that there is always a striking difference in the two images. It must be considered as proved by these observations that no spot on the sun can be regarded as being in a state of quiescence, even during so short a period, and that the changes are important enough to be perceived at the distance of the sun viewed from the earth, although the smallest spot observable must be regarded as having a surface larger than the whole of France, a second of arc on the sun being equal to the distance between Paris and Marseilles.

ADMIRAL MOUCHEZ has almost completed his museum of astronomy in one of the rooms of the Paris Observatory. Exclusive of the portraits of Bouvard, Arago, Leverrier, Cassini, and other directors, a series of the principal celestial objects has been painted on the walls by talented artists. In the middle is a glass case in which a number of instruments used by astronomers of former ages are exhibited. M. Mouchez intends to publish a monthly periodical, which will be called *Journal d'Astronomie*. A part will be reserved for the original communications of the astronomers of the Paris Observatory, and part devoted to reviewing foreign astronomical periodicals.

THE Paris Anthropological Society has recently awarded prizes as follows:—The Godard Prize (500 francs and a silver-gilt medal) to Dr. Le Bon, for a work on the development of the cranium according to civilisation, age, and sex; two honourable mentions (with bronze medals) to M. Ujfalvy, for the first volume of his "Journey in Turkestan," and M. Zaborowski, for his "Manual of Prehistoric Archæology;" the prize in French Ethnology to Dr. Chervin, for his statistical works; and honourable mention to M. Rivière for his prehistoric researches.

SIR WILLIAM THOMSON gave some valuable evidence on Friday before the Select Committee engaged in considering the subject of the electric light. He said that whereas one-horse-power of energy would only produce 12-candle gas light, it might produce 2,400-candle electric light. "The upshot of the experiments made at the factory of Messrs. Siemens, at Woolwich, and at the natural philosophy class of the University of Edinburgh, was that, allowing the practical estimate of one-horse-power applied in driving the engine, it had produced 1,200 candles of actual visible electric light, half the gross energy going to produce the light while the other half was lost in heating the machine and the wires. As the electric light was such an economical producer he anticipated that it had a great and immediate future before it. He believed before long it would be used in every case where a fixed light was required, whether in large rooms or small ones—even in passages and staircases of private dwellings. There was immense promise in the actual work carried out by practical men in the present day. There was a prodigiously greater economy in the transmission of mechanical force into energy in the case of the electric light than in the case of gas. With regard to regulators for the electric light, he had seen one the previous day—the Siemens regulator—which gave a steady, pure, and quiet light. The electric light was especially adapted for being placed high where it illuminated a wide area. It might be put upon an iron pole raised 60 feet high, or the old French plan of swinging a lamp on a wire from one side of the street to the other might be followed with advantage. Such a plan would be useful in doing away with the necessity for opal globes, which destroyed a large quantity of the illuminating quality of the light. Indeed, he was surprised that these globes had ever been used, wasting as they did 50 or 60 per cent. of the illuminating power. He considered that the advantages of using the electric light within buildings would be very great, because of the small effect it would have when compared with gas in heating and vitiating the atmosphere. In the case of electricity, the waves of light only became converted into sensible heat, not in the air, but on the ceiling or walls and floor of the room after they had done their work. With regard to the subdivision of the light, according to practical experiments, if the same amount of energy that was used in producing one large light was employed in producing ten feebler lights, none of those lights gave one-tenth of the amount of illumination of the one large concentrated light. Still there was nothing mathematically impossible in the matter, and it was quite possible that a plan of subdivision might be found by which the ten feebler lights would give a sum of illumination equal to that of the one larger light. He considered that the electric light as now developed was fit for use in large rooms. He was also of opinion that a great deal of natural energy which was now lost might be advantageously applied in the future to lighting and manufactures. There was a deal of energy in waterfalls. In the future, no doubt, such falls as the Falls of Niagara would be extensively used—indeed, he believed the Falls of Niagara would in the future be used for the production of light and mechanical power over a large area of North America. The electricity produced by them might be advantageously conducted for hundreds of miles, and the manufactories of whole towns might be set in motion by it. Powerful copper conductors would have to be used—conductors of a tubular form

with water flowing through them to keep them cool. There would be no limit to the application of the electricity as a motive power; it might do all the work that could be done by steam-engines of the most powerful description. It seemed to him that legislation, in the interests of the nation and in the interests of mankind, should remove as far as possible all obstacles such as those arising from vested interests, and should encourage inventors to the utmost. As to the use of electricity by means of the Falls of Niagara, his idea was to drive dynamic engines by water power in the neighbourhood of the Falls and then to have conductors to transmit the force to the places where illumination or the development of mechanical power was wanted. There would be no danger of terrible effects being brought about accidentally by the use of such a terrific power, because the currents employed would be continuous and not alternating." This may be called a fanatical view of the electric light.

On Tuesday night the electric light was put to rather a novel use, and one well calculated to test its practical and especially artistic value. At the Horticultural Society's *conversazione*, various forms of the light were adjusted so as to illuminate the magnificent array of fruit and flowers of all kinds and colours, with, we believe, complete success, the only drawback being the wretched state of the weather. Still it was clearly shown how admirably adapted this form of light is to any purpose in which it is essential that colours should be shown almost *au naturel*.

On Monday evening Mr. J. F. Bateman, president of the Institution of Civil Engineers, received at a *conversazione* at the South Kensington Museum a large assemblage of distinguished representatives of science, literature, and art. The long galleries of models of machinery and naval architecture were thronged with eight or nine hundred visitors, and brilliantly illuminated with electric lights, presenting a scene of exceptional brilliancy. The electric lights employed were of many different systems, including the Jablochkoff candle, Siemens's apparatus, that of the Electric Lighting Company, fitted with Wilde's automatic carbon holders, Higgins's incandescent light, and many others, displaying both covered and naked lights. Many noteworthy models of machinery had been specially added for the occasion by well-known engineers. Among these new contributions, which attracted a constant succession of interested groups of visitors, were in particular a working model of the writing telegraph of Mr. Cowper, and Dr. W. H. Coffin's modification of M. Trouvé's minute electric lamp for surgical use. These, however, were only two among the numberless objects claiming attention in an exhibition full of interest and instruction.

As usual the Geologists' Association have arranged an excursion for Whit Monday and Tuesday. This year it is to Bath, under the direction of Messrs. Charles Moore and W. H. Huddleston.

Mount Etna is in a state of eruption; on the 26th an opening occurred on the northern side, from which issued dense volumes of smoke and flames.

The administration of the scientific exhibition to be held at Paris from July to November next, is desirous to establish a special section of electricity if agreeable to intending exhibitors, consequently all the electricians who have subscribed already are requested to state their opinion.

A Zoological Society of New South Wales has been formed at Sydney; one of its chief objects is the acclimatisation of foreign animals.

The Midland Union of Natural History Societies held its second annual meeting at Leicester on Tuesday and Wednesday, May 20 and 21, under the presidency of Mr. Geo. Stevenson, who delivered an address to the large body of members from all parts of the Midland Counties, who met together in the Town Hall, Leicester. He pointed out how the usefulness of the Union might be best developed, and urged the members to co-operate together in definite efforts to solve some of the many problems of local and scientific interest. The first work of the kind which some of the societies had already taken up was an examination of the glacial drift deposits of the Midland districts, a scheme for which had been published by Mr. W. J. Harrison, F.G.S., one of the secretaries of the Union, in the *Midland Naturalist*. In due time the results of these efforts would be made public, and from what was already known of the labours of the inquirers some valuable information will be published. The Union now includes twenty-four societies, and there were representatives present from most of them. The societies in the Union (numbering nearly 3,000 members) are the following:—Birmingham Natural History and Microscopical Society, Birmingham Philosophical Society, Birmingham and Midland Institute Scientific Society, Birmingham School Natural History Society, Burton-upon-Trent Natural History and Archæological Society, Caradoc Field Club, Cheltenham Natural Science Society, Derbyshire Naturalists' Society, Dudley and Midland Geological and Scientific Society and Field Club, Evesham Field Naturalists' Club, Leicester Literary and Philosophical Society, Northampton Naturalists' Society, Nottingham Literary and Philosophical Society, Nottingham Naturalists' Society, Rugby School Natural History Society, Oswestry and Welshpool Naturalists' Field Club, Peterborough Natural History and Scientific Society, Severn Valley Naturalists' Field Club, Shropshire Archæological and Natural History Society, Small Heath Literary and Scientific Society, Stroud Natural History Society, Tamworth Natural History, Geological, and Antiquarian Society, Woolhope Naturalists' Field Club. In the evening of the first day a most successful *conversazione* and exhibition of microscopes, scientific apparatus, experiments, &c., was held in the Leicester Museum buildings. On Wednesday about 200 members made an excursion to Charnwood Forest, which was divided into two sections—one, geological, under the guidance of Mr. W. J. Harrison, F.G.S., and the other botanical, of which Mr. F. T. Mott, F.R.G.S., was the leader. The annual meeting in 1880 was fixed to be held at Northampton under the auspices of the Northampton Naturalists' Society; Mr. Edward W. Badger (Birmingham), and Mr. G. C. Druce (Northampton) were elected hon. secretaries for the year; and Mr. H. E. Forrest (Birmingham) assistant hon. secretary.

We are pleased to see that a Scientific and Historical Society has been formed at Launceston, under the presidency of the Rev. G. H. Hopkins. From the opening address of the president it is evident that the Society has formed a correct idea of what should be the work of a local society, and we trust that the members will work energetically together to carry out the programme thus sketched. The district covered by the Society may be said to include North-east Cornwall and North-west Devon between Dartmoor and Bodmin Moor, with the sea-coast on the north. The sections are archæology, botany, meteorology, zoology, and geology, and in all departments the district ought to yield rich fruits. The Society seems to have made a good start, and we shall watch its progress with interest. We trust it will enlist a large proportion of real workers.

An interesting experiment was made on May 22 before M. Tresca, the sub-director of the Paris Conservatoire des Arts et Métiers. M. Chretien, an engineer of Paris, has constructed a set of two locomotive ploughs worked by rope traction according to the Fowler system. But instead of using steam power, M. Chretien has employed the electric current generated by a Gramme machine, and a stationary steam-engine. It has been

determined by M. Tresca that one-half of the motive power generated by steam was really transferred to a distance of above one kilometre from the furnace. The motive power which has been utilised for farming land can be employed for excavating, or executing any description of work.

THE carrier-pigeon service is now in full operation in France, and has been placed under the direction of the head of aërial communication. The number of birds fed by the Government is 6,000. These pigeons are located in Paris and twelve other large fortified towns. A number of soldiers and officers have been taught the art of pigeon breeding, and carriers are constantly sent from place to place. The Minister of Public Instruction and the Minister of Agriculture have established prizes for pigeon races.

THE strong interest recently awakened in Owens College, Manchester, has been shown in a desire on the part of some of his admirers to do honour to the founder. This has taken the form of a memorial window, which is to be erected in St. John's Church, near the College; and the donors have commissioned Mr. W. G. Taylor, of Berners Street, to carry out the work, which will be completed towards the end of next month. At the foot of the three lights are the words "Ars, Religio, Scientia," symbolised by subjects illustrating music, charity, and astronomy. The arms of the College and of John Owens occupy the bases of the side lights.

ONE of the new Cardinals, Haynald, Archbishop of Kalocsa in Hungary, is eminent as a botanist, as we learn from the *Gardeners' Chronicle*, and is probably the first botanist who has ever held so exalted a rank.

THE Sanitary Institute of Great Britain has issued a very satisfactory second Annual Report.

WE note that Dr. W. G. Farlow, for the past five years Assistant Professor of Botany at the Bussey Institution, Harvard University, has been appointed Professor of Cryptogamic Botany in the University proper. This is the first professorship in this important and difficult department established in the United States. The laboratory for instruction and research in the lower cryptogamia is now established at Cambridge.

FOR the schools of California, "A Popular Californian Flora; or Manual of Botany for Beginners," has (in part) been lately published by Mr. Volney Rattan, teacher in the Girl's High School, San Francisco. A second part will complete it. It is restricted to plants of the San Francisco region, extending north to Mendocino County, south to Monterey, and west to the foot hills of the Sierra Nevada.

"CINCHONA CULTURE IN BRITISH INDIA" is the title of a useful pamphlet by Surgeon-Major G. Bidie, Superintendent of the Madras Central Museum, being one of the Museum Popular Lectures of the season 1878-9.—We have received a separate copy of a paper "On Pollen," by Mr. M. S. Evans, read before the Natal Microscopical Society on November 18 last.—The Fifth Report of the Boulder Committee of the Royal Society of Edinburgh contains notes on a considerable number of boulders in Scotland, with numerous illustrations.—West, Newman, and Co. publish a monograph by Mr. P. H. Gosse, F.R.S., on "The Great Atlas Moth of Asia (*Attacus atlas*, Linn.)," with a coloured plate of its transformations.—We have received a very favourable Report of the Condition and Progress of the Davenport (U.S.) Academy of Natural Sciences, which is now in its eleventh year, and doing good and varied work.—"On the Lancashire Coal Fields," is the title of a paper by Mr. C. E. De Rance, reprinted from the *Proceedings* of the Geologists' Association.—A fourth edition of Bloxam's "Laboratory Teaching" has been issued by Messrs. Churchill. The most important alteration is the introduction of the formulæ representing the various chemical compounds described in the notes in the tables.

THE additions to the Zoological Society's Gardens during the past week include a Grey-cheeked Monkey (*Cercocebus albigena*) from West Africa, presented by Mr. Robert Surry; a Patagonian Sea Lion (*Otaria jubata*) from the Falkland Islands, presented by Mr. F. E. Cobb; a Roseate Cockatoo (*Cacatua roseicapilla*) from Australia, presented by Mr. Head; a Blue-winged Green Bulbul (*Phyllornis hardwickii*) from India, presented by Mr. A. Jamrach; two Horned Lizards (*Phrynosoma cornutum*) from Texas, presented by Mr. E. Loder; a Javan Fish Owl (*Ketupa javanensis*) from Java, a Ceram Lory (*Lorius garrulus*) from Moluccas, three Abyssinian Guinea Fowls (*Numida ptilorhyncha*) from Abyssinia, a Nicobar Pigeon (*Calœnas nicobarica*) from the Indian Archipelago, a Victoria Crowned Pigeon (*Goura victoriæ*) from the Island of Jobie, a Mace's Sea Eagle (*Haliaëtus leucoryphus*) from India, two Black-tailed Godwits (*Limosa melanura*) twelve Common Widgeons (*Mareca penelope*), European, purchased; a Cheetah (*Felis jubata*) from Africa, two Bactrian Camels (*Camelus bactrianus*) from Central Asia, deposited; two Black Swans (*Cygnus atratus*) from Australia, received in exchange; two Chinchillas (*Chinchilla lanigera*), a Black-necked Swan (*Cygnus nigricollis*), bred in the Gardens.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

FROM No. 6 of the *University College School Magazine* (London) we see that the editor's post is not altogether a pleasant one, though the number is very creditable. The U.C.S. Scientific Society seems in a healthy condition. In connection therewith we notice that a series of sixteen lectures are to be given during this term on the Science of Daily Life. We trust they will be well attended.

FROM the Report for 1878 of the Rugby School Natural History Society we learn that it is fairly flourishing. The entomological, geological, and archæological sections have been vigorous, though the workers in each are fewer than they should be. Altogether there does not seem to us to be that hearty interest in the Society among the boys that conduces to complete success; all the more reason, therefore, for the real working members keeping up their work with unflagging zeal and doing their best to enlist the sympathy and help of the indifferent. A satisfactory observatory Report from Mr. Seabroke is appended.

SOCIETIES AND ACADEMIES

LONDON

Royal Society, May 1.—"On the Origin of the Parallel Roads of Lochaber, and their bearing on other Phenomena of the Glacial Period." By Joseph Prestwich, M.A., F.R.S., F.G.S., &c., Professor of Geology in the University of Oxford.

Of the various hypotheses that have been brought forward since the time of Macculloch and Dick-Lauder in 1818, to account for the origin of the Parallel Roads of Glen Roy, the one so ably propounded by Mr. Jamieson, in 1863, has been most generally received and adopted.[1] It is a modification of the views originally expressed by Agassiz, to the effect that the barriers of the lakes—to the shore action of which both the above-named geologists attributed the "roads," but were at a loss to account both for the formation and removal of barriers—had been formed during the glacial period by glaciers issuing from Glen Treig and Glen Arkaig, supplemented by others from Ben Nevis. The subsequent determination, by the Scotch geologists, of an intermediate milder period succeeded by a second cold period, led Mr. Jamieson, with whom the pre-glacial and glacial deposits of Scotland had been a subject of especial investigation, to conclude that the extension of these two places took place during the second cold period, which he thinks was of little less intensity than the first, and that, while the glacier from

[1] Darwin's well-known paper, in which he considered the "roads" to be old sea-beaches, appeared in the Philosophical *Transactions* for 1839. This marine hypothesis was afterwards earnestly advocated by R. Chambers and Prof. Nicol, but is no longer held by its distinguished author.

Glen Arkaig blocked up Glen Gluoy, the glacier from Glen Treig formed a barrier to Glen Roy.

The "roads" were, he considers, formed by long-continued shore action at each successive level of the lake, that level being determined by the height of the cols over which the lake waters escaped.

To these views it has been objected, by Mr. Milne-Holme and others, that it is difficult to conceive the glens to the north of the Spean Valley to have been filled with water while at the same time those on the south were filled with ice, and he advocates a detrital barrier formed of clay, sand, and gravel, by marine origin, when the sea stood some 3,000 feet higher than at present.

Prof. Nicol, also, has pointed out that, had lakes existed in Glen Gluoy, Glen Roy, and Glen Spean for the length of time required to form the "roads" by erosion, and to accumulate the deltas, the cols by which their surplus waters escaped during those periods must have cut a channel in the rocks in the same way that the rivers (which now represent the same drainage, or probably less) have since excavated their channels in the present valleys; whereas, although there are indications of water-wear in the passes, nothing like a defined river channel exists. Prof. Nicol attempted to explain the facts on the theory of the "roads" being sea beaches. But the absence of corresponding beaches outside those glens—the limitation of the highest "road" to Glen Gluoy—and of the second and third to Glen Roy, and the total absence of marine remains in any of the various drift beds, renders the marine hypothesis inadmissible.

Sir John Lubbock, looking at the form of the "roads" which has been described by Macculloch as parallel layers applied in succession to the sides of the hills, contends that such a form is incompatible either with the heaping up of materials on a shore line, or with their removal by erosion, as in the one case a notch and in the other a projecting ledge in the hill side would be formed, whereas, with one exception of one superior talus pointed out by Macculloch, no such structure exists. Sir John points out that a parallelism between the slopes may, however, have been formed by wavelet action, in consequence of the detrital matter taking, as it successively fell and was removed, the same angle of repose as that which the detrital slopes originally had, that angle being the same in water as in air.

Besides these objections to Mr. Jamieson's hypothesis, which the author considers valid, he points out the difficulty of conceiving that the Arkaig glacier could have ascended the hills at the entrance of Glen Gluoy to a height of not less than 1,200 feet, while at the same time a pass existed at the head of the glen only 500 feet high, which presented a ready outlet to the west coast.

It is a question also whether active glaciers such as Mr. Jamieson requires could have formed permanent dams to the large bodies of water pent up in Glen Gluoy and Glen Roy. Glacier lakes are occasionally formed in the Alps, as in the instance of the Margelen See; but they never last many seasons. The glacier is constantly on the move, and so long as it presents an unbroken front to the lake, so long is the barrier efficient, but when in the progress of the glacier a fissured mass of ice comes forward, the water at once escapes with greater or lesser rapidity, and cannot again accumulate until the defective ice has travelled past or the leak is repaired by winter frosts.

Equally difficult is it to imagine the existence of such vast glaciers as those of Glen Arkaig and Glen Treig, while the opposite glens of the Gluoy and Roy remained free from ice. The difference in the height of the hills is too slight to allow of so great a variation in the level of the snow line, and the cause suggested by Mr. Jamieson, viz., a great difference in the rainfall such as it now obtains in this district, can scarcely be maintained, for, although the annual fall at Fort William is 86 inches, and at Laggan 46 inches, the rainfall at Roy Bridge has now been found to be as much as 62 inches. Further, for the argument to be of any value, it should be shown that in the country further eastward, where the rainfall is much less, there was the like absence of glaciers during the second period, whereas Chambers and other geologists, including Mr. Jamieson himself, have shown that during that period local glaciers descended from every mountain range approaching or exceeding 3,000 feet in height—a height attained by the hills to the north as well as by those to the south of the Spean.

With respect to the so-called "deltas" of the Turret in Glen Roy, and of the Gulban in Glen Spean, which are supposed to have accumulated during the long time that the lakes filled the valleys, the author shows that the structure of the former is not in accordance with the bedded structure of deltas, but on the contrary, that it is formed of unstratified moraine *débris* 50 to 80 feet thick, with a thin coating of gravel water-worn and reconstructed from the underlying mass, and that the angle of terminal slope is not that of original deposition, but is due to wearing back of the terrace by the Roy, and the fall of the *débris* by weathering.

These are the objections of the author to the hypothesis of Mr. Jamieson, but while objecting to this exposition of the glacial theory, he considers that that theory affords the most satisfactory solution of the problem, only that he would suggest a different interpretation in explanation of the phenomena.

Dismissing the hypothesis of local glaciers of the second period of glaciation, the author falls back upon the original idea of Agassiz with the development acquired by more recent research, and assigns the Lochaber lakes to the close of the first period of great glaciation. He considers the phenomena are due to the peculiar physiographical conditions of the district, and shows that owing to the configuration of the country, the drainage of the Ben Nevis range is diverted into the lower part of the Spean Valley and the Great Glen near Fort William. These conditions which now give this area an excess of water drainage, must in the like manner, during the glacial period, have there led to an exceptional accumulation of ice.

The observations of MacLaren, Chambers, Milne-Home, Jamieson, James Geikie, and others, sufficiently prove the great thickness of the ice covering in this part of Scotland during the first period of intense glaciation. On the flanks of the Ben Nevis range, glacial striæ extend to a height of more than 2,000 feet, while everywhere the rocks in the lower parts of Glen Spean are intensely glaciated, as are also those at the head of Glen Roy on approaching the Col to Glen Spey, and around the Cols of Glen Glaster and Makoul. At the same time, the erratic blocks, with the beds of sand and gravel of foreign origin, which have been found widely distributed over the hills around Glen Roy to heights of from 800 to 2,100 feet, afford confirmatory testimony of the depth of the land ice which then covered the country.

With the incoming of this glacial period, local glaciers must have descended from every mountain range, and so long as the glacier of one steep glen became confluent with another of the same chain flowing in the same general direction, so long would their course be uninterrupted, and the propelling and abrading force maintained, as in the Alps at the present day; but when, emerging from these glens into valleys of small gradients dividing the several mountain chains, they met with glaciers descending from these other ranges, their progress was not only subject to be checked, and their forces neutralised, but their course diverted, for if the lines of natural drainage were barred, the ice took those of least resistance, although such might be uphill and against the lines of drainage. This, however, could not be effected without excessive pressure and heaping up of the ice at the points of junction.

These interferences must have been especially frequent in the valley of the Spean. On the one side, the glaciers descending the steep ravines of the Ben Nevis range, would issue into Glen Spean and project across it to the Glenroy hills opposite. Below to the west, the great Nevis Glen glacier emerged into the valley of the Lochy, while above to the east the great glacier, issuing from Glen Treig, flowed down Glen Spean; but, meeting with the aforesaid group of glaciers from Ben Nevis, was partly diverted over the flanks of Craig Dhu, and upon the entrance to Glen Roy.

While the glaciers from this system of mountains were becoming confluent in and filling Glen Spean, those from the opposite range of hills were descending Glen Roy, the Rough Burn, and the other ravines of that chain, and coming into collision with those of the Ben Nevis range. In the same way other valleys were focussing their glaciers upon the end of the Great Glen north of Ben Nevis, barring in that direction the passage of the ice down Glen Spean, and diverting it northward towards Loch Lochy and Loch Oich.

Therefore, the great mass of ice descending Glen Spean, in consequence of meeting with these obstructions, was driven to accumulate in mass in the lower part of that valley opposite Glen Roy, until overcoming further resistance and confluent with the Ben Nevis mass, it wheeled round into the Great Glen at Loch Lochy.

There is no doubt, also, from the direction of the striæ and

the position of the transported boulders, that the mass of the Treig glacier struck across the valley of the Spean, and turned down its channel westward; but that a part ascended to the Col of Glen Glaster, and another passed up the Spean Valley, is doubtful. It is more probable that this glacier, after traversing Strath Spean, met with others coming down the Rough Burn, while these took an easternly direction to Loch Laggan and over the Pass of Makoul. The direction of the striæ observed by the author between the Rough Burn and Moy, points, he considers, to ice coming down from the hills on the north and joining this main east stream.

The effects of these great conflicting ice streams were not confined only to the piling up and accumulation of the ice. Although glaciers confined by the walls of narrow glens, and descending steep slopes exercise great abrading power, the observations of Charpentier and others show that when they emerge into broader and flatter valleys, they may pass over beds of loose detritus without disturbance except that of pressure. The terminal moraines of the many glaciers emerging into Glen Spean may, according to the varying conditions of the ice, have been pushed forward or rolled over by the ice, while the meeting of conflicting glaciers must have led to the deposition and heaping up of the glacial *débris* at the points of junction. The many checks and blocks that must have occurred during the growth of the great ice-sheet—the neutralisation of the ice-force in one place, and the centralisation of it in others—will serve to explain much that is peculiar in the distribution of this sub-glacial *débris* or Till, not only in Lochaber, but in other parts of the country, and at all levels.

The author then points out the many mounds and terraces in the Spean Valley formed of moraine detritus, though since levelled and often masked by a covering of gravel due to subsequent water action. To this cause also he attributes the large accumulation of *débris* at the entrance to Glen Roy, between Bohuntine and Glen Glaster, where he shows it to be in places 200 to 300 feet deep, and where it rises nearly to the level of the lower parallel road. Mr. Milne-Home has pointed out a similar deposit at the entrance to Glen Collarig, while the large mass at the entrance of Glen Spean, and now forming Unachan Hill, rising to a height of 613 feet, has been often described.

The next question discussed is the height of the land in relation to the sea at the period of the great glaciation, as it is not possible to suppose that with the great changes of level which took place subsequently, there is now a return to the *status quo ante* of the earlier period; and the author sees reason to conclude that the land then stood at not less than from 1,000 to 1,500 feet higher than at present, so that the Irish Channel was then above the sea level, and land extended a considerable distance westward from the present coast of Scotland.

This was followed by a submergence of not less than 1,200 to 1,500 feet in central and northern England, Wales, and Ireland, and of 600 feet in the southern part of Scotland, as proved by the occurrence of marine shells at those heights, and assuming for the north of Scotland a submergence, at all events, of 400 or 500 feet below the present level, this, added to the previous elevation of 1,000 to 1,500 feet, would establish a difference of 1,500 to 2,000 feet between the period of great glaciation and the succeeding period of submergence.

This difference of level would produce a twofold effect upon the climate—the one resulting from altitude which would be equal to a rise in the mean temperature of from 4° to 6° F., and that caused by the conversion of a continental area into an archipelago. The effects of the two causes could not be less than from 12° to 15° F., which is about equivalent to the difference of climate between Paris and St. Petersburg. There is also to be taken into account the probable increase of heat consequent on the gradual diminution of those conditions, whatever they were, to which was owing the cold of the glacial period.

The effect of those changes was to produce a thaw which gradually led to the destruction of the great ice-sheet, though subsequently other changes brought for a time a return of cold sufficient to maintain local glaciers in the higher mountain ranges. The conditions under which the ice-sheet would be placed during this period would be similar to that of glaciers where they extend below the snow line. In Europe the glacier gradients are usually so steep, and the ice is so fissured, that even in such positions water rarely lodges on the surface, but in the Himalayas, where glaciers descend into wide valleys with small gradients, and the summer heat is considerable, the glaciers often become covered with tarns and small lakes. They have been noticed by Sir J. D. Hooker, and more lately by Col. Godwin-Austen, who describes in the middle of one of these glaciers, a series of such lakes, some being 500 yards in length, and 200 to 300 in breadth, and of great depth. As intervening barriers give way, these lakes descend from lower to lower levels, and finally escape.

In the same way the old ice-sheet must have become covered with pools and lakes, for owing to the irregular surface of the ice, and the inevitable absence of all channels of drainage, the water must everywhere have lodged, until channels were formed, and a means of escape established. The extent of these bodies of water would depend upon the height and permanence of the obstructions. In the Lochaber district they were, owing to the causes before named, of great size and permanence, such as to form high barriers at the entrance to Glen Roy, Glen Spean, and Glen Gluoy, behind which the waters accumulated and rose until they found a channel of escape over the cols at lower levels, when a permanent water-level would be established so long as the main barriers existed.

It is well known that the Parallel Roads are terraces composed of perfectly angular fragments of the local rocks with a few rounded pebbles both local and foreign to the district. The former show an entire absence of any prolonged beach wear. The wear of the latter is due to other causes. The slope of the hills above and below the "roads" varies from 25° to 40°, and the inclination with the horizon of the "roads" themselves, which are from 50 to 70 feet wide, varies within the limits of from 5° to 30°.

Of the internal structure of the "roads" very little is known. The only published section is the one given by the Rev. Thomas Brown in his paper on the "Parallel Roads," and in this there is no appearance of any such structure as would result from successive additions to the ledge by the tipping over of *débris* removed from the shore.

Although, therefore, the "roads" indicate a line of water-level, there is nothing in their form or structure to show that they have been formed by the long-continued action of lake waters on a shore line. To what, then, are they to be ascribed?

What the conditions were immediately antecedent to the formation of the first, second, and fourth road, is not shown, but in the case of the third road the conditions preceding its formation are to be traced uninterruptedly from the conclusion of No. 2 "Road." When the lake stood at the level of "Road" No. 2, its waters escaped by the col leading to Glen Spey, while, when they stood at the level of No. 3 "Road," they escaped by the Glen Glaster Col. Now, as there is a difference of 76 feet between the height of the two cols, it is evident that a barrier must have existed on the latter col during the time the lake stood at the higher level. Whether the barrier was detrital or ice-formed is immaterial for the argument.

Now, it is well known to engineers that a breach once established in a detrital barrier becomes so rapidly enlarged that, if not at once stopped, nothing can stay the rapid destruction of the barrier, as, in the case of the Holmfirth, Crinan, and other floods. Nor is evidence wanting of similar catastrophes in connection with glacier lakes. In the notable case of the Gietroz Glacier barring the valley of the Drance, a lake nearly 2 miles, and at one end 200 feet deep, was drained in twenty minutes. The still greater flood recorded by Vigne in a branch of the Indus drained a lake formed by a detrital barrier, and estimated by Mr. Drew to have been 35 miles long by 1 mile broad and 300 feet deep at its lower end, in one day.

In the same way it is to be assumed that the Glen Glaster barrier, which was probably formed by a remnant of the glaciers descending from the mountain ranges (2,994 feet) at the head of the glen, gave way with great suddenness, and caused the rapid fall of the waters from the level of the higher "road" in Glen Roy to that of that glen's second "road," at the height of the Glen Glaster Col, when the escape of the waters was stopped.

Now, it must be borne in mind that at this time the great mantle of snow and ice which had so long covered the country was passing away, leaving the surface of the hills in Glen Roy covered with a thick coating of angular local *débris* mixed with sand and clay, the result of the intense cold and of the decomposition of the underlying schistose and granitic rocks. This and the glacial *débris* must have long remained bare and unprotected by vegetation; at all events that below the water-line was so. Now, the angle of repose of purely angular and subangular *débris* varies within the limits of from 35° to 48°, but that of clayey sands, which, when dry, is from 21° to 37°, becomes,

when saturated with water, as low as 14° to 22°. The angle of repose of the hill-side *débris* would, therefore, depend on the relative proportion of the angular materials and their matrix, and on the extent of saturation. The slopes of the hills being on the whole greater than that of the angle of repose of the saturated under-water rubble, this latter, easily set in motion on the settlement of its constituent parts as the water drained from it would, as the level of the lake water fell, tend to slip or slide down with the falling water, and this slip would continue until the disturbing cause ceased, and the momentum of the mass was checked by the inertia of the water gradually coming to rest on reaching the level of the col of escape.[1] The effect of the arrested slide would be to project the mass more horizontally forward, and form a ledge. This ledge, modified slightly by subsequent subaërial action and weathering, and by the dressing of its slope on the occasion of the next fall of the lake, constitutes the "road."

Although in the case of the other "roads" there is not the same evidence of a minor col-barrier, as the results are alike in all, the causes which led to them must have been the same; and it is shown that there is nothing incompatible in the features of the ground with the existence of such barriers, or rather that there is some evidence in each glen, however slight, of water-lines at levels higher than the "roads."

Comparing the theoretical inferences of structure with the facts, so far as they are known, Mr. Brown's substratum of "clay with boulders indistinctly stratified with thin (lenticular) layers of sand," represents the sliding detrital mass; the finely stratified sand and clay—the sediment which subsided from the muddy lake waters after their fall; and the two to three feet of stones with clay—the subaërial fall of *débris* from the slopes above. In the substratum and overlying sediment, Mr. Brown found four species of fresh-water diatoms, while he found none in the upper bed. This fact serves to confirm the subaqueous origin of the body of the ledge, while it tends further to disprove the marine hypothesis.

Although there is in all the cols an entire absence of a defined water channel, such as would be worn by the long-continued flow of a river, there are in all of them traces of strong water action, such as might result from the temporary passage of a large and rapid body of water.

With respect to the main barriers acting as dams to Glen Gluoy, Glen Roy, and Glen Spean, they were due, as already pointed out, to the circumstance of an accumulation of ice at these spots so excessive and so high as to last long after the ice generally in the lower tracks had given way. Not, however, that any ice barrier could have been permanent for a great period of time, but this the author's hypothesis does not require. In any case, an ice-barrier in a state of rest will form a more effective barrier than when in motion.

Passing over the barrier at the entrance to Glen Gluoy, it is shown that the point where the Glen Roy barrier existed is that where a glacier coming down Glen Roy would meet in opposition the ice from Ben Nevis and the Spean Valley; and that this glen was occupied by a glacier is proved by the occurrence of glacial striæ on the rocks forming the bed of the valley near Dalriach, and of Till, or boulder clay, lower down the valley, nearer Achavady. But the great mass of the latter lies precisely on the spot where the Ordnance Survey have placed the line of barrier; it was there heaped up by the same conflicting causes that produced the barrier of ice. That it was originally larger and higher is proved by its occurring on the two sides of the valley, the river having worn a channel through it, and by the presence upon it of thick beds of water-worn and water-strewn gravel, the materials of which have been derived from the underlying deposit, and which was formed, in all probability, by the rush of the waters on the bursting of the barrier, for, in many places the gravel is thrown back and over, as though by downward and outward pressure of water in motion. This detrital mass extends for a length of two miles or more.

The great barrier needed at the entrance of Glen Spean is precisely on the gronnd that the great glaciers of Ben Nevis met the ice stream coming down Strathspean. Unachan Hill, which rises immediately behind the line of barrier marked by the Ordnance Survey, together with the rising ground on the flanks of the valley, consist of a thick substratum of till or boulder clay, with a covering of gravel, the latter formed in greater part, if not entirely, from the destruction of the former, so that there is little doubt that the detrital barrier here also was at one time much more important. Still, although the detrital matter formed a considerable element, the author believes that the great mass of ice constituted the essential element in the barriers.

The Till, although accumulated in larger masses in the above-named sites, is found in places all up the valley, generally in the form of terraces covered by gravel, as at Inverroy, Murlaggan, Inverlaire, and elsewhere. There is one feature common throughout, namely, the levelling and terracing of this glacial *débris* by subsequent water-action, which could not have been effected in the still waters of a lake bed, but probably took place on the bursting of the main barriers and during the rapid outflow of the waters. The levelling of the original glacial mounds having been effected at the time of the drainage of the lakes, and having been then covered and masked by gravel, the terminal slopes were either formed at the same time by the outpouring waters as they fell to a lower level, or subsequently by wearing back by the present streams.

An objection may occur to the foregoing hypothesis, in that, with elements so variable as the problem has to deal with, the parallelism of the "roads" with the horizon, which has been remarked on by all observers from Macculloch downwards, could not have been maintained. For the detritus of the hill sides vary, however slightly, in the relative proportions of rock fragments and soil, while the slopes above and below the "roads" vary also in their angle, so that, as these conditions varied, so would the momentum of the sliding mass vary, whilst the resisting force of inertia would remain the same. The consequence would necessarily be, that the slide would continue at some places to a lower level than at others, and the line of the "roads" could not be throughout parallel with the horizon.

There is no doubt that, to all appearances, the "roads" are perfectly level, and such was the author's first impression; but afterwards, on referring to the elaborate 6-inch Ordnance maps, he found the levels there given clearly show that the "roads" are neither at the exact height of the cols nor are they perfectly parallel with the horizon, after allowing for the variable inclination of the "roads," and for the observations being made in their centre.

Instead of a perfect level water line, the "roads" are really slightly *waved*, the difference between the highest and lowest point being in the four "roads" taken in descending order, 15, 11, 15, and 12 feet; and while the level of the higher "roads" is in most instances *below* those of the several cols of escape, that of the lower "road" is in all instances *above* it. Thus in Glen Gluoy, the "road," which is never more than 1 foot above the level of the Turret Col, is in places 14 feet below it. The Glen Roy "roads," Nos. 2 and 3, rise 2 and 4 feet above the col of the Spey, and sink 7 and 13 feet below it; whereas No. 4 "road" is never less either in Glen Roy or Glen Spean than 2 feet, and rises at places to 10 and 14 feet, above the Pass of Makoul. Further, as the curves formed differ for each "road," the variations *cannot be due to a common cause, such as subsequent movements of the ground*, but must be owing to differing conditions in each case. Nor do the levels on the two sides of the valleys correspond; they often vary as much as 7 or 8 feet. It is therefore not possible to reconcile these variations with the hypothesis of the "roads" being lines of water level due to shore action; nor is the very variable inclination of the "roads" themselves compatible with that view.

In the higher "roads" the lower level of the curve is possibly due to the steeper slopes, whilst the fact that the lower "road," No. 4, remains above the level of the Pass of Makoul, may be due to the circumstance either of the slopes being less, or more probably to the fact of the lake having been so very much larger, the escape of the waters was more prolonged, and the fall slower.

Various phenomena in connection with the great ice-sheet in Lochaber, and their connection with the gener l question, are next considered. The author objects to the term of *moraine profonde* to describe the drift of sub-glacial origin, as apt to lead to misunderstanding, although Hogard and other geologists have used it in a wider sense. It is evident that the old ice-sheet acted under very different conditions to an ordinary glacier, and it is better to use such terms as moraine detritus or sub glacial detritus for the sum total of sub-glacial products of the former, than employ a term which was originally and still is generally restricted to a single and comparatively small product of the modern glacier.

Besides this sub-glacial *débris*, there is the larger quantity of

[1] Even now considerable slides occasionally take place on the steeper slopes of Glen Roy.

débris that must have been scattered over the surface of the ice during its melting by streams and rivulets, or spread out in the temporary lakes which were formed at all levels, and may have given rise in many instances to sand and gravel terraces of variable extent. But though true beaches may be deposited in other glacial lakes, for ledges or shelves such as constitute the Parallel Roads to be formed, a number of conditions must have concurred—such as sufficient slopes, a detrital covering, barriers at the mouth of the glens, and cols of escape at their upper end.

As the barrier ridges on the old ice-sheet melted, or burst, the waters escaped to lower levels, carrying with them, on or beneath the ice, a large portion of the surface detritus. Formed at all levels up to 2,000 feet or more, these glacial lake waters, in descending to lower levels, met with yet larger bodies of water, and the transporting forces increased in power till the last stage was reached and open channels formed in the distant plains, leaving as marks of their passage down the valleys—here great banks of gravel—there deep beds of sand, according to the distance from the point of outburst. To these floods, combined with river inundations, and with the modifications wrought by subsequent fluviatile action, are due various forms of escars, terraces, and other less defined detrital accumulations.

Meteorological Society, May 21.—Mr. C. Greaves, F.G.S., president, in the chair. The following were elected Fellows of the Society:—A. C. Bamlett, C. Browne, H. Burkinyoung, W. Radford, F. Ramsbotham. The adjourned discussion on the Rev. W. Clement Ley's paper on the inclination of the axes of cyclones was resumed and concluded. The object of this paper is to call attention to the evidences recently afforded by the results of mountain observations to the theory that "the axis of a cyclone inclines backwards." The author first reviews the state of the question up to the present time, and details his own investigations chiefly founded upon the movement of cirrus clouds; he then refers to Prof. Loomis's recent "Contributions to Meteorology," in which is discussed the observations at the summits and bases of several high mountains, the results of which confirm the theory that the axis of a cyclone inclines backwards. The following papers were read:—On observations of the velocities of the wind, and on anemometers, by G. A. Hagemann.—On the relation between the height of the barometer and the amount of cloud, as observed at the Kew Observatory, by G. M. Whipple, F.R.A.S. The author shows that the average amount of sky clouded at Kew is a little less than seven-tenths of the whole, and that the amount covered varies inversely as the barometric pressure between the limits of 29·0 and 30·3 inches, the variation being the most rapid between 29·8 and 30·1 inches. Also that above 30·3 inches cloud increases with increasing pressure, attaining the mean about 30·5 inches, and rising above it at 30·6 inches.

PARIS

Academy of Sciences, May 19.—M. Daubrée in the chair.—The following papers were read:—Meridian observations of small planets at the Greenwich and Paris Observatories during the first quarter of 1879, communicated by M. Mouchez.—On the resistance of elliptical boilers, by M. Resal.—On a new derivative of nicotine, by MM. Cahours and Etard. This is got by heating nicotine (100 parts) and sulphur (20 parts) together. The sulphur acts first by removing hydrogen from the nicotine. When at 160° to 170° the mass has become fluid and chrome-green in colour, the heating is stopped; and in a few days yellow prismatic crystals are formed of the new substance. Sundry reactions are described. The authors consider nicotine as probably a combination of dipyridine and hydrogen. Sulphur, acting on 2 molecules of nicotine, transforms it, with separation of sulphydric acid into *tetrapyridine*.—Formal reasons of the economical superiority of the Woolf or compound engines, by M. Ledieu. These are shown in tabular form.—Researches on the proportion of carbonic acid in the air, by M. Reiset. He operated with large aspirators, of about 600 litres capacity, movable to various parts. He finds that free atmospheric air contains, on an average, 2·942 vol. carbonic acid per 10,000 vol. (The common statement is that the quantity in atmospheric air varies between four and six ten-thousandths in volume.) In very diverse conditions the extreme variations did not exceed 3 per 100,000. Comparative observations in woods and in fields showed small differences, the numbers being 2·917 CO_2 and 2·902 CO_2 respectively, for the same hour. Other cases were: Over a field of red flowering clover in June, 2·898 CO_2; over one of barley with luzerne, in July, 2·829 CO_2. Among a flock of 300 sheep in pasture, 3·178 CO_2 (showing a considerable increase); at Paris, in May, near the Parc Monceaux, 3·027 CO_2.—M. Daubrée communicated news of M. Nordenskjöld. Whalers had seen what was probably the *Vega*, blocked in ice near Behring Strait, not far from East Cape.—Mr. A. Hall was elected Correspondent in Astronomy in room of the late M. Santini.—On the transparence of the media of the eye for ultra-violet rays, by M. Soret. He operated with the eyes of oxen, calves, and sheep, using his spectroscope with fluorescent eye-piece. It is shown that the absorption by the whole of the media must render impossible the perception of rays whose refrangibility exceeds that of the extreme radiation of the solar spectrum, or the line U. The absorbent properties of the vitreous and aqueous humours are attributed to presence of albuminoid substances. The limit of transparence of the two humours is indicated by curves.—Independence of changes of diameter of the pupil and of variations of the carotidian circulation, by M. François Franck. The iris may be dilated or contracted independently of modifications of the circulation.—A letter from Buffon to Laplace in 1774 was communicated by the Marchioness de Colbert-Chabanais.—On the characteristics of functions Θ, by M. Jordan.—On functions such as $F(\sin\frac{\pi}{2}-x) = F(x)$, by M. Appell.—On a property of entire functions, by M. Picard.—On the functions introduced by Lamé in the analytical theory of heat relating to ellipsoids of revolution, by M. Escary.—Preliminary study of the action of acids on salts, without intervention of a solvent, by M. Lorin. The results indicate in general a chemical action more or less marked, and which for fatty acids decreases from formic acid to each of its successive homologues. Applications:—1. Crystallisable acetic acid may be obtained with acetate of baryta and sulphuric acid. 2. Formic acid may be had, *very concentrated*, with sulphuric acid and formiate of ammonia.—On the presence of mercury in the mineral waters of Saint-Nectaire, by M. Willm. He confirms M. Garrigou's conclusion (which had been denied), though the quantity of mercury he got was much less.—On the changes of volume of the spleen, by M. Picard. The dilatation of this organ results from dilating nervous actions exercised on the digestive organs, while its contraction results from a special well-determined nervous action.—Researches on alterations of the blood in uræmia, by MM. Morat and Ortille. Carbonate of ammonia is always found in the blood, unless death come before the end of the second day. Its presence there is posterior to its presence in the alimentary canal.—On the mode of combination of iron in hæmoglobine, by M. Jolly. His analyses confirm a former conclusion, that iron exists in the blood corpuscle only in the state of phosphate.—On hæmatoxylic eosine and its employment in histology, by M. Renant. It reveals, by an elective coloration, the two orders of cells which constitute by their union a mixed acinus of the sub-maxillary salivary glands.—On the apparatus of sound in various South American fishes, by M. Sörensen. Vibrations are communicated to the air of the swimming bladder.—On the amyloid appearance of cellulose in champignons, by M. De Leynes.

THURSDAY, JUNE 5, 1879

SCIENCE TEACHING IN LONDON BOARD SCHOOLS

IT was a fortunate circumstance that at each of the three elections of the School Board for London science has been represented. On the first occasion Marylebone gave Prof. Huxley a seat at the board, and at the second and third elections Chelsea has sent Dr. Gladstone as one of its representatives. To the former was due, in great measure, the Code of Regulations in which the subjects of instruction were laid down. To the latter has fallen the task of bringing them into a systematic and practical form. The Committee, of which Prof. Huxley was the chairman, determined that there must be given, in infant schools, "object lessons of a simple character, with some such exercise of the hands and eyes as is given in the Kindergarten system"; and in boys' and girls' schools, "systematised object lessons embracing in the six school years a course of elementary instruction in physical science, and serving as an introduction to the science examinations which are conducted by the Science and Art Department." The time-tables of all the schools under the Board are made to conform to these requirements; the walls of the class-rooms are hung with illustrations in natural history and other diagrams; and in many of the schools boxes of objects are also to be found. Many of the teachers, especially those trained by the Home and Colonial Society, endeavour to carry out the regulations as fully as practicable; but hitherto the scheme has worked very irregularly, and there has generally occurred a break of continuity on the children passing from the infants' departments to the upper schools. The Board's Inspectors, who are required to report in all cases on object teaching, have often had to bear testimony to this defect.

In November last the Store Sub-Committee, of which Dr. Gladstone is chairman, prepared a systematic scheme to supply the deficiencies of the former regulations, which has been adopted by the Board. The syllabus is as follows:—

Infants' School (Non-Standard Children).

Aim.—To develop in the children's minds an interest in the things round and about them; to teach the use of all the senses, and form habits of observation; to impart a correct knowledge of the commonest things; to increase the infants' vocabulary and power of expressing themselves.

Subjects of Instruction.—Objects illustrative of the three kingdoms of nature—animals, plants, and minerals, especially such as the children meet with commonly in their ordinary life. The different parts, qualities, and uses of these objects.

Means.—Diagrams; objects procured by the teacher or supplied from the store, and a small case of apparatus to enable the teacher to perform the simplest operations necessary to illustrate the properties of the objects. Children are to be encouraged to bring the needful objects both in this and subsequent stages.

Standard I.

Aim.—To carry on the previous training, leading also to the exercise of the judgment, in showing the relations of the different parts of bodies, and how their different qualities fit them for the uses to which they are applied.

Subjects of Instruction.—A somewhat more extended series of objects, with fuller information as to the qualities, uses, and history of common things.

Means.—Diagrams of animated nature, &c., classified—small cabinet of objects, classified for purpose of comparison, with simple apparatus as before.

Standards II. and III.

Aim.—To lead up from the previous training to the "specific subjects" of the Code.

Subjects of Instruction.—Series of objects illustrating the most important manufactures. Geographical distribution of products and means of procuring them. Objects for teaching the fundamental notions of matter and force.

Means.—Diagrams—same small cabinet as before. Loan collections of objects tracing the raw material to the final product (such as cotton, flax, silk, leather, wool, iron, and clay).

Standards IV. to VI.

Aim.—To teach the "specific subjects" of the Code.

Subjects of Instruction.—One at least of the following:—

Mechanics. Taught by diagrams and working models (on loan).		
Physiology.	ditto	models (on loan).
Physical Geography.	ditto	maps and experiment.
Botany.	ditto	specimens and models.
Domestic Economy.	ditto	demonstrations and experiment.

The practical instruction which, during such a course as the above, will be imparted to the children, is altogether in advance of what is contemplated by the new code of the Education Department. The Government have provided that an annual grant of 4*s.* per subject be given for every scholar in the Fourth, Fifth, and Sixth Standards passing in not more than two of these "specific subjects;" but they give no grant for any of the preliminary teaching which under this scheme is intended to lead up to these studies. This defect in the scheme has been brought before the notice of Parliament year after year by Sir John Lubbock. The London School Board has therefore decided, on the motion of the Hon. George Brodrick, that an application should be made to the Education Department to get the teaching of the elements of natural science included among the recognised subjects of class examination—history, geography, and grammar; and a deputation will shortly wait upon the Lord President of the Council with that object.

This will manifestly be a step of very prime importance not only to the School Board for London, but to all those in the Provinces, and to the cause of education in general, as the possibility of thus obtaining a grant for the teaching in the lower standards will be the most effective stimulus that can be applied. Whatever, however, may be the result of this application, the London Board will not be deterred from fully carrying out the programme they have set themselves; and they have prepared a circular of instructions to their teachers, full of excellent and valuable suggestions, which is to be

accompanied by a box of apparatus, simple and cheap, to enable the object-lessons to be properly illustrated. Loan collections of models illustrative of mechanics, physiology, and botany, will also be provided; but as far as possible the children are to be encouraged to bring familiar objects, and to make their own models and apparatus. After giving very full directions for the teaching of the infants and the first standard children, which we need not insert in detail, the course prescribed for the upper classes is as follows:—

Standards II. and III.

As the aim in these standards is to lead up to the specific subjects of the Code, the teaching must be more advanced, and should make a larger demand on the thinking powers of the children.

The objects contained in the previous groups should be again employed, but fresh ones should be occasionally introduced, especially for the purpose of comparison.

In the animal group children should be led to compare and classify the different animals, and to notice the chief differences and resemblances between the leading divisions of the animal kingdom. The children should also have explained to them the preparation, qualities, and uses of animal substances employed in the arts, such as leather, silk, wool, and horn.

In the vegetable group such distinctions as that of endogen and exogen should be made clear; the gradual growth of plants such as beans and wheat should be traced; the uses of vegetable substances, such as cotton, linen, starch, sugar, coffee, tea, and india-rubber, with the processes of manufacture, should be explained.

In the mineral group attention should be called to the general properties of metals, iron, copper, silver, gold, lead, tin, zinc, mercury, &c., and the qualities peculiar to each. The iron and steel manufactures, and the making of bricks, pottery, earthenware, &c., may be explained; and the distillation of coal and manufacture of gas, may be experimentally illustrated.

The knowledge of the points of the compass, and form and motions of the earth, which is required by the Code, will naturally be imparted by means of object lessons.

This object teaching may be connected, as occasion offers, with the lessons in geography, and may often be made to illustrate the reading and dictation lessons.

The teacher is not expected to attempt to teach all the subjects mentioned in the preceding paragraphs, nor to limit himself to them, but the Inspector will inquire what particular course the object lessons have taken, and will frame his examination accordingly, taking care that the fundamental facts connected with matter and force are not overlooked.

Standards IV. to VI.

Though in the higher standards one or more of the scientific specific subjects of the Code is expected to be taken, it will be generally found necessary to continue some of the training just described. Thus, in the Fourth Standard, lessons on the principles which are at the foundation of all physical, mechanical, and chemical science should be given; during which clear ideas should be imparted as to size, weight, and specific gravity, as to the laws of motion of solids, liquids, and gaseous bodies, as to the production, radiation, conduction, and absorption of heat, and as to the difference between chemical combination and the mere mixture of the constituents. Occasional lessons also on the atmosphere and its composition, and the ordinary meteorological changes should be given, and local phenomena of springs, streams, hills, ponds, excavations of the soil, &c., should be observed. Boys as well as girls should be taught something of the laws of health. Domestic economy should not be taught empirically, but the scientific principles involved in the lighting of a fire, in cooking, in the choice of clothing material, in washing, and in ventilation, should be experimentally explained.

The foundations of a "knowledge of common things," as Dr. Lyon Playfair happily called it, will thus be well laid; and the children of the London schools will at an early age acquire the habit of correct observation—no mean advantage whatever may be their future occupation in life. This additional course of instruction will not occupy more than about two hours a week, and will involve scarcely any extra expense, while it will sharpen the wits of the children and freshen their minds for their more literary studies.

NOAD'S "ELECTRICITY"

The Student's Text-Book of Electricity. By H. M. Noad, Ph.D., &c. A new edition, carefully revised, with an Introduction and Additional Chapters by W. H. Preece, M.I.C.E., &c. (London: Crosby Lockwood and Co., 1879.)

IN his introductory note to this new edition of the "Student's Text-Book of Electricity," Mr. Preece informs us that the revision is only partially his own, having been begun by Dr. Noad shortly before his lamented decease. In fact a large portion of the work appears to be reprinted from former stereotyped plates.

In addition to a large number of illustrative cuts, the work possesses a very valuable feature, too rare in elementary books, namely, frequent references to important original memoirs. A judicious use is made of extracts, as, for example, from the lectures of Prof. Fleeming Jenkin on submarine telegraphy, and from those of Sir W. Thomson on atmospheric electricity and terrestrial magnetism. New chapters on telephones, duplex and quadruplex telegraphy, and on the electric light, bring up the scientific information to the present year. As an elementary treatise on the purely phenomenal side of the science of electricity, it is probably the fullest text-book in the language.

Having said this, our commendations must end. Mr. Preece's opening paragraph bears the stamp of being an excuse for the shortcomings of the work; and we must regard it as his misfortune, rather than his fault, if a book which he has had to revise fall far short of what it might have been had it been produced under his sole responsibility. It is unfortunately—in science, at least—the reviewer's duty to be candid on the shortcomings of the work under his notice; and the only way to prevent the repetition of erroneous statements, and to secure their effective correction, is to point them out fearlessly. We are bound, therefore, to undertake the ungracious task of indicating sundry blemishes which it is to be hoped will not be perpetuated in another edition.

There appear to be several discrepancies between the earlier and the later parts of the book. On p. 178 mention is made of "a battery known as the *Pile Marie Davy*," in which *sulphate of mercury* is used; and which is stated to be *weaker* than Daniell's cell, but to have *been used to some extent in France.* On p. 434 appears an account of the "*Marié-Davy Battery*," which "has been *much used in England, and is largely employed in France and on the Continent.*" It is twice stated to contain *bisulphide of mercury;* and lower down on the same page it is declared on the authority of Latimer Clark to have an electromotive force of 76, as compared with 56 for a Daniell's cell.

The divided ring electrometer of Sir W. Thomson is described on p. 79. Another description and a figure of the instrument are given on p. 529. The quadrant electrometer, of which there is no mention in the early chapter where Peltier's and other electrometers are given, is described at some length and figured on p. 537.

In a couple of pages devoted to the "Insufficiency of the Contact Theory" of voltaic electricity, the authorities cited are Faraday, Roget, and "lastly," Sir W. Snow Harris; the later fundamentally important researches of Hankel, Thomson, Kohlrausch, and Clifton, being absolutely ignored.

Two pages (22 and 23) are devoted to Varley's multiplier, but there is not a word about the earlier invention of Nicholson, nor the more recent "replenisher" of Sir W. Thomson. Nor is there a single word about the Holtz machine.

In magnetism there is no attempt to explain the meaning of the term "declination," and the word "variation" is made to do duty both for declination and for the variation of declination, in a manner most perplexing to the uninitiated in electrical terms. And yet the book is avowedly "written under the idea" that the student "approaches the subject from the datum line of ignorance!"

We cannot accept without protest the following statement:—

"The fall of tension is always accompanied by its conversion into heat" (p. 198). Nor this: "With sulphuric acid the iöns (*sic*) are H and SO_4 (Sulphionide of Hydrogen)."

The term the "*absolute quantity of electric force in matter*," used on p. 223, is open to serious objection. On p. 209 we read that "the common non-absolute unit of work involving the product of a weight into a length is styled *kilogramme*, or foot-pound."

The following statement:—"we have, calling C the charge, Q the quantity, and S the surface, $C = \frac{Q^2}{S^2}$," appears on p. 61. After pondering over this formula, we give it up.

We are compelled to take exception to the following manner of stating the well-known law of Ohm:—"Thus let F denote the actual force of the current, that is, its power to produce *heat*, magnetism, chemical action, *or any of its other effects;* E the electromotive force, and R the resistance of the wires and liquids, then $F = \frac{E}{R}$" (p. 199). To say nothing of the assumption that all the "effects" of the current are simply proportional to the current strength, we protest against the introduction of that much-abused word, *force*, where every other treatise on electricity in the language has put "strength" of current or "quantity" of current or "intensity" of current. On p. 209 the formula again appears, this time as $C = \frac{E}{R}$, which is the form adopted by Maxwell, Jenkin, Culley, Foster, Chrystal, the British Association Committee, and in the well-known treatises of Ganot and Deschanel. Guthrie uses $Q = \frac{E}{R}$, and the form $I = \frac{E}{R}$ is used by Maxwell, Cumming, Clark and Sabine, Verdet, Daguin, Wiedemann, Jamin, and continental writers generally. It is very desirable that needless departures from one or other of the established forms should be discouraged. The "Return Charge" of the Leyden jar, so-called on p. 46, is now almost universally denominated the "residual" charge, a term which is far preferable, as it cannot be confounded with the return shock or return stroke, or "back stroke," as it is termed on p. 91.

In the chapter on the telephone occurs the following passage:—"In 1874 Mr. Elisha Gray, of Chicago, America, succeeded in effecting the transmission, through a wire, by means of electricity, of the variable intensity, as well as the pitch of a sound. Subsequently he invented a form of telephone by which all the three characteristics of sound could be transmitted. *As a result, the electrical transmission of articulate speech became an accomplished fact.* It remained, however, for Prof. Graham Bell, of the Boston University, to accomplish this latter feat in the most effective manner." Do we understand Mr. Preece to endorse Elisha Gray's claims to precede Bell as the inventor of an *articulating* telephone? As a minor blemish, we notice the name of Philip Reis appears as Reiss. Many persons confound the inventor of the original singing telephone with Peter Riess the author of the *Reibungselectricität;* and the misspelling of his name helps to perpetuate the error. One other quotation from the editorial add tions is not devoid of interest:—

"The subdivision of the (electric) light has recently occupied the attention of inventors. Jablochkoff works four lamps simultaneously. Wallace has worked ten. Attempts have been made to do this on a much larger scale by raising platinum and iridium to incandescence, or to that temperature just below melting-point. A soft and gentle light is thus obtained. But the result has not been commercially successful, *though probably this is the direction in which ultimate success will be obtained*" (p. 576).

We wish heartily that the editor of this new edition had himself re-written the work; a reviewer's task would then have been much more agreeable.

SILVANUS P. THOMPSON

LENZ'S SKETCHES FROM WEST AFRICA

Skizzen aus Westafrika. Selbsterlebnisse von Dr. Oscar Lenz. (Berlin: Hofmann and Co., 1878.)

DR. LENZ'S "Sketches from Western Africa" are unusually interesting and instructive. They are not descriptions of travel in the ordinary sense of the word, but form a collection of essays, perfectly independent of each other, describing in a masterly manner the natural and social conditions of that scantily investigated coast, as they presented themselves to the eminent

traveller during a journey undertaken at the request of the German African Society, and extending over three years (1874 to 1877). Everything, therefore, which Dr. Lenz describes, he has seen and witnessed himself, and apart from this important advantage the sketches have that additional one, that they are written from a completely unprejudiced and neutral point of view as far as the social or political conditions of the various West African tribes are dwelt upon. Thus a series of no less than fourteen different pictures of travel are presented to the reader, and it is indeed difficult to determine which of them are the most interesting.

After a condensed account of the previous exploring expeditions, and an explanation of the great difficulties attending all travels in Western Africa, Dr. Lenz begins his first sketch with the French colony of Gaboon. In June, 1874, he landed for the first time on African soil, viz., on the small island of Elobi in the Bay of Corisco. This bay is situated in lat. 1° N., between Capes Ninje (St. Jean) and Esteiras and contains the three islands—Corisco, the larger and the smaller Elobi; Spain numbers these islands amongst its colonies, as is also the case with the large and well-wooded island Fernando Po, a few degrees further north, with its high volcano called Clarence Pic. Between Capes Santa Clara and Pongara the sea forms a wide inlet into the coast of the mainland, and here the French have established a colony in the fine estuary of Gaboon and have extended their influence even to the mouth of the mighty Ogowe River. Two large rivers, the Muni and the Mundah, the sources of which are situated in the outskirts of the West African Slate Mountains, or the Sierra do Crystal, have their estuaries in the Bay of Corisco, which has flat banks thickly clad with evergreen mangrove trees. These mangrove swamps form the dark and dense wall which here protects the African continent against European trespassers, as they give rise to the fatal fever miasma which has won for this coast the unenviable reputation of being the most deadly one in the world. Many a traveller who landed here full of hope and with a view of exploring the interior and adding his share towards making it accessible to commerce and civilisation, has acquired in these mangrove swamps the germs of premature death; many an active and striving colonist who sent home to Europe the costly natural products of the land and who introduced to the natives the useful appliances and productions of the "n'tangani," *i.e.*, white men, here fell a victim to the ever-prevalent fevers.

From Elobi Dr. Lenz proceeded to Gaboon, a journey which in the opposite direction a steamer can perform in about eight hours, but which on account of both wind and tide coming in a south-northerly direction took some three days in a sailing vessel. The sanitary conditions of Gaboon are much better than those of the coast a little further north, yet malaria fevers are frequent. The annual mean temperature, although the colony is situated almost on the equator, does not rise beyond 27–28° C.; yet the fact that the thermometer never sinks below 20° C. makes the climate unbearable to all Europeans in the long run. The best months for travelling here are June, July, August, and the beginning of September. In the middle of the latter month the rainy season sets in and lasts till the middle of January, when a short dry season begins, lasting to the beginning of March. Then another rainy period commences and continues to the end of May. It is very peculiar that during the long dry period from the end of May till September the sky is invariably overcast, while during the rain season the sun sends down its perpendicular rays with all their intensity, the sky covering itself with heavy rain clouds only towards evening.

Dr. Lenz mentions a curious fact in connection with the sanitary conditions on the west coast of Africa:—

"It appears that amongst the European colonists each one thinks his particular place of residence to be the healthiest of all. Thus the colonists at Banana, a sandy strip of land near the mouth of the Congo, consider this place extremely healthy and know of no worse parts for fever than the Gaboon districts; but in the latter the colonists make the sign of the cross if the Congo is mentioned. The inhabitants of St. Paul de Loanda are in raptures about their upper town (in the lower town, close to the sea, there are only stores and shops) and others again designate this largest town of West Africa, the only place indeed which has a right to the name of town, as the worst plague-hole in the world. Unfortunately there is no place on the west coast which is unanimously designated as healthy (perhaps with the only exception of Mossamedes, in the south of Benguela), but on the other hand there are a number of districts about the deadly climate of which nobody is in doubt. To these Gaboon distinctly does not belong, while Cape Lopez in the delta of the Ogowe estuary does; and so does the island of Fernando Po and a number of the so-called 'oil rivers,' such as Camerun, Old and New Calabar, Bonny, Opobo, &c., places of great importance in the palm-oil trade."

The native population of Gaboon belongs to the great family of Bantu negroes, and they call themselves Mpungwe. They are a relatively fine race, and certainly superior in frame and growth to the neighbouring Akelle, Okota, and others. They have not progressed very much in civilisation in spite of their long connection with the French, yet there exists a tolerably friendly feeling betwixt them and the colonists; they are even to a certain extent guided by French laws. Their political significance is very small; the last of their kings, Denis by name, died two years ago aged over ninety years. The Mpungwe live in little huts, of which some ten or twenty form a village, and these are disseminated in every direction among the "factories" of the Europeans. The former occupation of the native Gaboonese was solely and exclusively slave trading, but at present their principal object in life seems to be to obtain goods on credit from European colonists, and to exchange them against gums, ivory, or ebony in the interior. Apart from this the slave trade still flourishes among the Mpungwe themselves, indeed the wealth of a Mpungwe nigger consists principally in the number of his slaves, whom, however, he treats very kindly. Polygamy of course exists generally among the West African natives, also with the Mpungwe, although most of the latter call themselves Christians. But with all this the superstitious customs and fetish creed of past centuries exist to this very day, and if the wealthy Gaboonese laughs at them in public he yet continues the same old religious humbug on his travels into the interior. Apart from the Gaboonese proper, the Mpungwe, different other tribes live close to the European colonies, such as the mighty Fan and

Akelle. These strive to replace the Mpungwe. To the north, towards the Mundah River, the Osekiani, the Mbenga and Mbuschu tribes are met with, which occupy the whole area of the Bay of Corisco. All these tribes speak different languages and differ in their manners and customs.

The colony of Gaboon consists of three little villages inhabited by Europeans—Plateau, Glass, and Baraka (or Libreville). They are situated about a mile from one another. The French Government house, offices, and barracks, as well as the Catholic Mission house and four or five factories are at Plateau; eight or ten English and German factories are at Glass, and the Anglican Mission house is at Baraka. Each factory forms a complex of houses by itself, all comprised in an inclosure; there is generally the dwelling-house of the colonist, the sale rooms or shops, a store-house, a kitchen (always built separately), a house for the workmen, and a shed for canoes and boats. The houses are built of wooden planks imported from Europe, and all have a verandah. The roofs are covered with mats, which are impenetrable even to the most violent rain. The only house built of stone is the Government house.

Dr. Lenz now gives minute details on the political condition of the colony as well as of the work and progress of the religious missions, and concludes his sketch by an elaborate account of the commerce of the place.

In the above we have given but a scanty outline of Dr. Lenz's sketch of Gaboon. Our readers may judge of the interest of the whole work when we state that there are thirteen other chapters equally elaborate and crowded with details. Our space will not permit us to enter further upon the subject, and we must confine ourselves to the mere statement of the contents of the other chapters. Thus we have one on the Cape Lopez colony, then the Ininga, the Fan and the Abongo tribes are treated in turn, the Fan being remarkable through their being cannibals and the Abongo through their extraordinarily small size, which entitles them to the appellation of a "tribe of dwarfs." A general description of the commercial conditions of West Africa follows, and we then come to some animated pictures of elephant and other hunting. The next chapters treat of the superstitious beliefs of the various tribes, of the free state of Liberia and the Croo Coast. A journey from the Okande land to the Osaka tribe and thence to the Aduma and the Banshaka is described in the three following sketches, and the two last ones are dedicated to a description of the Ogowe Lakes and the town of St. Paul de Loanda. We can recommend Dr. Lenz's book most heartily to all lovers of geographical and ethnographical science who are familiar with the German language.

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts. No notice is taken of anonymous communications.*

[*The Editor urgently requests correspondents to keep their letters as short as possible. The pressure on his space is so great that it is impossible otherwise to ensure the appearance even of communications containing interesting and novel facts.*]

The Average Flush of Excitement

I WITNESSED a curious instance of this on a large scale, which others may look out for on similar occasions. It was at Epsom, on the Derby Day last week. I had taken my position not far from the starting-point, on the further side of the course, and facing the stands, which were about half a mile off, and showed a broad area of white faces. In the idle moments preceding the start I happened to scrutinise the general effect of this sheet of faces, both with the naked eye and through the opera-glass, thinking what a capital idea it afforded of the average tint of the complexion of the British upper classes. Then the start took place; the magnificent group of horses thundered past in their fresh vigour and were soon out of sight, and there was nothing particular for me to see or do until they reappeared in the distance in front of the stands. So I again looked at the distant sheet of faces, and to my surprise found it was changed in appearance, being uniformly suffused with a strong pink tint, just as though a sun-set glow had fallen upon it. The faces being closely packed together and distant, each of them formed a mere point in the general effect. Consequently that effect was an averaged one, and owing to the consistency of all average results, it was distributed with remarkable uniformity. It faded away steadily but slowly after the race was finished. F. G.

Lunar Crater

ON April 1 last I saw, between Landsberg and Rheinhold, a small but very remarkable crater, which does not appear in Schmidt's map. It is situated east of a line joining the centres of the above craters, and at rather more than a third of the distance from the former to the latter. Either closely adjoining, or in the position of the small crater, there is an isolated hill within the angle of a forked ridge as shown by Schmidt, who must, undoubtedly, have noticed the crater if it existed at the time of his observation. Might it be that the hill seen by him subsequently opened out as a crater? I remarked neither the hill nor the ridge, but these, like many of Schmidt's objects, might be above my telescopic power, so I cannot say whether the crater is identical with the hill or not. Nearer Rheinhold there is a smaller crater not in Schmidt, who, however, shows a similar one that I failed to see not far off to the south. This may be only a case of misplacement in the map.

JOHN BIRMINGHAM

A Remarkable Meteor

A REMARKABLE meteor was seen in Western Australia on February 1 this year. The following account has been forwarded to me by Mr. S. Worsley Clifton, Collector of Customs at Freemantle:—

"A small black cloud on a clear day appeared in the east, travelling not very swiftly towards the north-west, which burst into a ball of fire with an apparent disk the size of the full moon, blood-red in colour; it left a train of black or dark-coloured vapour across the heavens which was visible for three-quarters of an hour. No sound was heard, sky perfectly clear, and thermometer 100° F. in the shade." ROBT. J. ELLERY

Observatory, Melbourne, April 16

Disease in Salmon

THERE has lately been much correspondence upon the subject of a disease affecting the scales of the salmon, and I chanced to come upon the passage which I inclose to you in an old book, the fly-leaf of which bears the autograph of *a* Duke of Richmond, the one, I imagine, who was at Brussels in 1815. I am not a scientific naturalist, and it is quite possible that this passage is familiar to those who are conversant with such subjects; but thinking it better to err on the side of superfluity than that of carelessness, I trouble you with it. W. WALKER

May 26

Extract from Rev. C. Cordiner's Letters to Thos. Pennant, Esq., on Antiquities and Scenery of the North of Scotland. Lond. 4to, 1780.

I here beg leave to introduce a memoir, relative to an insect attendant on the salmon which come up this river (the Devron), communicated to me by an ingenious friend.

The foul salmon, of which a drawing has been already sent to Mr. Pennant, was caught February 10, 1776. When brought into the house the colours upon this fish were remarkably lively. The general appearance was that of a reddish brown; but the

spots of red and black upon particular parts, were exceedingly bright and beautiful. When one compared the whole appearance to that of a clean fish, it was wretched and disagreeable; it was lank; the belly empty, flabby, and of a dirty yellow; the jaws at a considerable distance in the middle, the under jaw with a large protuberance standing perpendicular upon the extremity; the upper jaw with a hole almost quite through (and I am told in some quite through), in which, when the jaws were shut, the protuberance lodged. Not one fin entire; the scales and skin being in many places destroyed, presented the appearance of foul ulcers. The gills were full of the *Lernæa salmoneæ;* such salmon are called *Kipper*, or foul fish.

The cruves in the river Devron are (following the windings of the river), about a mile and a half from the sea. In the sandy places below the cruves, where there is a sufficient depth of water, a great many salmon spawn. In those places they are seen raising considerable hills of sand, probably to cover and protect the spawn.[1] They are likewise seen frequently pushing and striking one another; and the fishermen assert that they have many battles: their conjecture is that the battles are occasioned by the males endeavouring to get at the spawn in order to devour it, and the females endeavouring to defend it. About these hills they remain during the winter, and until the young fry appear, unless forced off by a torrent, probably in order to keep the hills in repair and to defend the spawn from the many enemies ready to attack it. *Quære*,—Are not the form of the jaws, the foul ulcers in the skin, and the destruction of the fins owing to the above-mentioned operations? *Quære*,—If salmon spawned in the sea, would they not be found more or less in the condition of kipper? But in this condition they are never found out of the rivers.

Linnæus says of the LERNÆA *Salmonea: "Habitat in branchiis salmonum; ergo etiam marina:"* this latter is certainly a mistake; for these *Lernæa* are never found with us out of the rivers; and several sensible fishermen have assured me, that salt water proves absolute destruction to these animals.

Salmon, at a certain time during their stay in the sea, are infested by another animal of that genus, called by *Linnæus* MONOCULUS, which is as really a marine, as the other is a fresh-water animal. This species seems to me to be undescribed by authors and very distinct from the *M. piscinus* of *Linnæus*, which it in some measure resembles. In a few hours after a salmon has entered the river, not one of these MONOCULI are to be found upon it. *Quære*,—Have we not in these *vermes* a provision made by the Author of Nature for forcing the salmon from the sea into our rivers, and from the rivers back again into the sea?

Inherited Memory

YOUR correspondent "A. B." has propounded a theory which would satisfactorily explain a good many facts in natural history which have hitherto been extremely perplexing. I am strongly inclined to believe that in some of our birds, at any rate, the knowledge of localities is inherited. About thirty years ago I lived at a farmhouse, my father's home; the house stood alone in the country; my father also occupied some premises in a village, about half a mile distant. On these premises there was a large, very old dove-cot containing blue rock pigeons.

My brothers and I wished to establish a similar dove-cot at the farm, and prepared a suitable room for the purpose. In the first instance we caught, one winter's night, about fifty of the old rock pigeons; these we confined for five or six weeks, but when liberated they of course flew straight home. We next took a number of fledged young ones out of the nests. These had never been outside the old dove-cot, but when sufficiently strong they all flew away, as the old ones had done.

Discouraged, but still determined to succeed, we next bought a number of tame pigeons, and when they began to sit we put eggs of blue rocks under them, taking their own eggs away. Several were reared; but as soon as they were strong enough to dispense with the care of their foster-mothers, they one after another deserted them and returned to the ancestral dove-cot. A few years after this the premises where the old dove-cot was situated were altered, and the way into the dove-cot quite stopped up. The pigeons were sold and driven away.

For nearly twenty years blue rocks continued to visit the old premises. Some of them built on a ledge in an old gateway, that being the place in which it was possible for them to find nest-room the nearest to the old dove-cot. These occurrences seem to point to remembrance of localities in the race as well as in individuals, and "inherited memory" would, I think, best account for *all the facts* of the case. JAMES ELLIS

The Gynsills, Leicester

A Golden Eagle and a Decoy—Audacity of a Hawk

WHILST staying a few days at Manhattan, a little town in Kansas, I spent some hours in the office of a dentist, Dr. C. Blackley, who is also an ornithologist, having stuffed a goodly number of the birds of the state. He was then occupied with a fine specimen of the common pelican (*Pelicanus communis*) one of a flock of over a thousand that passed over the town in the month of April, some of them alighting in the neighbouring marshes. These birds are not unfrequent visitors to these far inland regions, and I have known them shot and brought to me from the alkali lakes in Colorado, both regions from 600 to 800 miles from the sea. The doctor told me an amusing incident of a day's wild goose shooting in the vicinity. He took with him to one of the ponds frequented by wild geese, a stuffed specimen of the Canada goose, to act as a decoy. Having firmly planted his bird in the sand with its wooden platform well covered over, he lay behind the bushes awaiting a shot. Suddenly there was a rush of wings, and like a flash of lightning a golden eagle swept down on the decoy, knocking the bird over, and tearing out some of the stuffing. The eagle then sat down near his prey, staring with amazement at its remarkably quiescent character, as well as at the strange wooden appendage attached to its claws. Deeming there was something uncanny about such a goose, and there might be danger in the neighbourhood, he prudently flew away. Unfortunately a branch of a tree prevented the sportsman from shooting the marauder.

(I can vouch for the truth of this story; the doctor showed the goose and where it had been struck).

A few days after this, when in the village of Morrison, Colorado, I was struck with the audacity of one of our smallest hawks. I was standing on a lumber pile in the middle of the street, when I heard a scuffling of wings, and a squeaking; the latter proceeded from a small prairie squirrel, about the size of a rat, who was making the best of his way to a hole in the lumber, hotly pursued by a tiny hawk, whose body was no larger than that of his prey. The squirrel just escaped into the hole by the tip of his tail, the hawk unable to stop the impetus of its onset, dashing right against the lumber-pile, within six feet of where I was standing. I jumped down in pursuit, but totally regardless of my presence, the plucky little bird made another swoop at his prey, who had again made a sally from another hole. I knocked the hawk down this time with my hat, and the squirrel escaped under the wood pile. This took place in the centre of a little village street, with bystanders within a few yards of the occurrence.

The hawk resembled the female sparrow-hawk (*Falco sparverius*). A. LAKIS

INTELLECT IN BRUTES

NOW that the discussion on this subject in NATURE seems to be running dry, perhaps a few concluding remarks by one who has not hitherto taken any part in it may be admitted.

The discussion was started by Mr. Nicols recording a case of the gnawing of water-pipes by rats. This is not at all an unusual thing for rats to do, and I cannot see that the fact of their doing so, in order to obtain the water, would imply so incredible an amount of sagacity as some of the other writers in NATURE appear to suppose. The water can be heard within the pipe, and if the rats are thirsty, it seems a sufficiently simple device to gnaw the pipe. Of course it may be an open question whether they gnaw the pipe for this purpose, or for the mere sake of gnawing, or for any other purpose; but that a rat should have sufficient intelligence to gnaw through a water-pipe, supposing the animal to require water obtained in this way, I think there can be no doubt.

The discussion was enlivened by Mr. Henslow introducing certain general propositions as to the features wherein animal intelligence differs essentially from human, and it

is upon this topic that I should now like to offer a few remarks.

Although Mr. Henslow has not been very fortunate in the expression of his views, I think he has before his mind the most essential, as well as perhaps the most conspicuous, quality wherein animal intelligence differs from human. He says: "It has always seemed to me that brute reasoning is always *practical* and never *abstract*. They do wonderful things suggested by the objective facts before them, but, I think, never go beyond it. Thus, a dog left in a room alone rang the bell to fetch the servant. Had not the dog been taught to ring the bell (which, on inquiry, proved to have been the case), it would have been abstract reasoning, but it was only practical. The Arctic fox—too wary to be shot like the first who took a bait tied to a string, which was attached to the trigger of a gun—would dive under the snow, and so pull the bait down below the line of fire. This is purely practical reasoning; but had the fox pulled the string first out of the line of fire *in order* to discharge the gun, and *then* to get the bait, *that* would have been abstract reasoning which he could not attain to."

To this Dr. Rae replies: "To pull the bait downwards *out of the line of fire* was the only safe way for the fox to have acted. . . . . Had he used what Mr. Henslow calls 'abstract reasoning'—which, I presume, means pulling the bait, not the line, to *one side* out of the line of fire—the fox would certainly have been shot, as the bait could not have been moved more than four or five inches from the wooden stake through which the bait-line passes.

"If Mr. Henslow really means that the fox should have shown his powers of 'abstract reasoning' by going up to the line of fire between the gun and the bait, and then pulled the string until the gun went off, I think the chances of reynard's ever eating the bait would be very small indeed. I have known him do what showed equal or greater intelligence, namely, cut the bait-string, as already mentioned."

It having been thus clearly shown that the "practical reasoning" of the fox was more to the point than the "abstract reasoning" of his critic, and several others of your correspondents having supplied more or less well-authenticated instances of the display of deliberative reasoning by brutes, Mr. Henslow concluded his part in the correspondence by modifying his original statement thus:—"I will abandon my notion of abstract reasoning, at least as hitherto described, for I now think that what I meant by the want of the faculty would be better described as an impotence, or, at least, a feebleness of mind in concatenating correlative ideas; or, perhaps, a want of receptivity of the suggestiveness of things will express my meaning." Owing, perhaps, to a feebleness of mind in concatenating correlative ideas, or perhaps to a want of receptivity of the suggestiveness of things, for my own part I cannot perceive these words to express any meaning at all—or, at least, any meaning that is not flagrantly absurd. I have never known an animal unable to concatenate the idea of eating with the correlative idea of the thing suited to be eaten, and very few among the higher animals show any want of receptivity of the suggestiveness of such a thing as a whip. The truth is Mr. Henslow has only darkened his meaning by this latest multiplication of words. What he originally intended to say is, not that animals do not possess *any* power of abstract thinking, but that this power is in them feeble as compared with what it is in man. Abstract thinking means thinking in or of abstractions, *i.e.*, of qualities as apart from particular objects. Now it would be absurd to maintain that no animal has any idea of quality except as in association with particular objects of past experience. Give a cat or a dog some kind of meat or cake which the animal has never before met with, and the careful examination which the morsel undergoes before it is consigned to the mouth proves that the animal has properly abstract ideas of sweet, bitter, hot, nauseous, or, in general, good for eating and bad for eating, *i.e.*, abstract ideas of quality as apart from the object examined—the motive of the examination clearly being to ascertain which general idea of quality is appropriate to the particular object examined. Thus Mr. Henslow cannot mean that animals possess no power at all of abstract thought. What he must mean is that this power is manifested in an extremely undeveloped form, the mind of an animal being only furnished with abstract ideas of the simplest or least elaborated type, and being therefore unable to carry on for any considerable distance the process of forming and joining ideas irrespective of suggestions supplied by immediate sense-perceptions. In other words, as Mr. Henslow himself very clearly states the case in one of his earlier letters, "it is this *mental reflection* which seems to me to be wanting in animals."

Taking, then, this as the only meaning which Mr. Henslow has to convey, it is, I think, the only meaning which with philosophical justice he can have to convey. For the more that we push analysis into the region of brute psychology, the more do we become convinced that the only very considerable difference between it and human psychology consists in the comparatively small development of the power of "mental reflection."

And here I may remark that this is just the difference which the theory of descent would lead us to anticipate as the chief, if not the only, difference; for it is evident that this difference has reference to the highest qualities of mind—*i.e.*, those most removed from simple mechanical responses to stimuli supplied by the senses—and therefore to the qualities which must have been of the most recent development. The tree psychological has been a long time in growing; its roots are constituted by mere excitability, reflex action is its stem, its branches are the association of ideas, the emotions are its leaves, and the faculty of abstract thought is a single blossom borne upon its topmost spray. And if we compare this tree with that of zoology, we find that the single blossom of the one corresponds with the highest product of the other. *Homo sapiens* is the lord of creation, because, having sprung from the primates he started with some little power of abstract thought, which, through the instrumentality of continuously improving language, was forced on by natural selection at a probably astounding pace.

So far, then, as the theory of descent is concerned, there is no serious difficulty presented by this chief point of difference between animal and human intelligence.[1] I think, however, that both in this connection, and also for the sake of comparative psychology, it is desirable to say that although Mr. Henslow has, in my opinion, stated the only great difference that obtains between human and animal psychology, there is no reason to think that this difference is so great or absolute as he appears to suppose.[2]

[1] I may here remark that a great deal too much stress seems to me to be laid by many writers on the presence of self-consciousness in man as a feature distinguishing his mind from that of animals. For this faculty, it seems to me, is obviously one that *must* arise so soon as the power of forming abstract ideas has advanced sufficiently far to admit of an animal thinking of itself as distinct from its surroundings. And this is surely not any so enormous an advance as to be impossible without supernatural assistance. A semi-human animal might well have had an abstract idea of thou, you, and they, and also an abstract idea of its own body as being more or less similar to that of its fellows. From this to an abstract conception of I, as distinguished from thou and not I, the transition seems sufficiently easy; and when once the idea of self began to dawn, it would be assisted by reflection, rendering past states of consciousness objective to present ones. But the idea of self *plus* the power of introspection is all that can be meant by self-consciousness.

[2] In saying that Mr. Henslow has stated this difference to be the only one that obtains between human and animal psychology, I do not forget the remarks with which he concludes his correspondence. These remarks may be summed up in his own words—animals "cannot be self-conscious, cannot conceive of God, and can neither be moral nor immoral." As all these distinctions between human intelligence and animal intelligence clearly rest upon, or are included in, the distinction above considered in the text, it is needless to occupy space with considering them in detail. Although I have myself maintained that on the theory of evolution we might antecedently expect the more intelligent and sympathetic of the higher animals to present the germs of a moral sense, and further, that in the case of dogs this expectation seems sometimes to be realised, this, of course, is a widely different

Several of the instances which your other correspondents supplied, would, as Mr. Henslow himself admits, "if correctly stated, and *if the motive* of the animals could in every case be proved, completely overthrow my supposition that animals never copy us with the same or a rational purpose." And even if we allow, for the sake of argument, that none of these instances have been "correctly stated," yet there are such a multitude of other instances on record of substantially the same kind, that it is impossible to doubt that animals present the beginnings of "mental reflection." Not to occupy too much space, I shall confine myself to stating a few instances which have not hitherto been put on record. Mr. Henslow says, "Why is it that no dog ever (to my knowledge, of course) observed a person ring a bell, noticed that the bell brought the servant, and then went through the process of reasoning—'Because such was the result I will ring the bell too?' This I call abstract reasoning." Well, Mr. Lawson Tait tells me that he has a cat which, without having been taught, does precisely what is here imagined. That is to say, when the cat wants milk and cannot persuade the persons in the sitting-room to supply her wants, she touches the bell, with the evident purpose of attracting attention to her wants in a more emphatic manner. The animal must have observed that ringing the bell has the effect of calling the servant, who sometimes brings milk, and therefore when her solicitations are unheeded or misunderstood, she makes a sign which conveys her meaning more conspicuously and more explicitly than she is able to make with her voice. Although this is no doubt a very remarkable case,[1] it is really only a higher manifestation of the faculties of observation, reflection, and communication by signs, which in lower degrees are met with in many animals. Thus, I myself had a terrier which used to express all his desires—even the sexual—by the same sign, that of "begging;" but he was able to make this general sign of desire express the particular thing desired by the manner in which he performed the sign. Thus, for instance, if he wanted water, he used to go to a wash-hand stand, or other place where he had observed that water was kept, and beg with his face towards the water-jug. I adduce this instance because, while it involves the manifestation of the three faculties above-named, it does so in a comparatively low degree, and therefore serves a stepping-stone to their higher manifestation in such instances as that of Mr. Tait's cat. There is nothing so very extraordinary in a dog observing that water is frequently poured out of a certain jug, and reflecting, "I can make my thirst known to my master by begging towards the jug." Yet this involves the same faculties of mind as does the ringing of a bell for a servant as a sign for desiring milk—the only difference between the two cases consisting in the more direct nature of the association and rational sign, Water, Water-jug, Begging towards water-jug, than of the association and rational sign, Milk, Servant a milk-bearer summoned by bell-pulling, Pulling bell to summon servant. Thus, so long as we have abundant evidence of the presence in animals of the faculties of observation and reflection in a low degree, we need not, as evolutionists, be over-solicitous to meet with the presence of these faculties in a higher degree, although as a matter of comparative psychology it is of interest that the highest degree to which such faculties attain in various species of animals should be ascertained. Among the instances which have been published in NATURE, perhaps the most remarkable is that communicated by Dr. Frost—the case, I mean, of the cat sprinkling crumbs to entice birds. I would suggest that Dr. Frost ought to supply more particulars as to where the cat obtained the crumbs, whether or not she had to carry them, and if so, to what distance, how she scattered them, and generally to furnish all the information that he can. So extraordinary does this case appear, that it ought to be stated with all possible minuteness. I have indeed met with alleged cases of precisely similar ingenuity—one displayed by a fox, another by a bear, and so on; but some well-observed instance is required to render these similar instances in any degree credible. Dr. Klein has told me of a case which resembles that of Dr. Frost's cat up to a certain point. For Dr. Klein satisfied himself that the cat he observed had established a definite association between crumbs already sprinkled on the garden-walk and sparrows coming to eat them; for as soon as the crumbs were sprinkled on the walk the cat used to conceal herself from the walk in a neighbouring shrubbery, there to await in ambush the coming of the birds. The latter, however, after all, showed themselves more wideawake than the cat, for there was a wall running behind the shrubbery, from the top of which the birds could see the cat in her supposed concealment, and there a long line of sparrows used to wait, watching the cat and the crumbs at the same time, but never venturing to fly down to the latter until the former, wearied with waiting, went away. In this case the observation and reasoning of the cat—Crumbs attract birds, therefore I will wait for birds where crumbs are scattered—was as complete as in the case of Dr. Frost's cat; but the reasoning in the latter case seems to have proceeded a stage further—therefore I will scatter crumbs to attract birds. And just because it is so rare a thing to find an animal taking this further step in reasoning—the step, I mean, from passive expectation to active adjustment—I think that Dr. Frost ought to be requested to supply more detailed information.

As further evidence of "mental reflection" by animals, I may give a few additional instances.

thing from supposing a dog to be either a moral agent or a religious animal. No one with an atom of common sense could entertain such a supposition for a moment; for morality and religion are among the highest products of abstract thought. Some time ago I had to give a lecture on evolution at one of our large provincial towns. Next Sunday the vicar told his congregation that there could be no truth in the modern doctrine, and the reason he gave had the merit of being boldly startling. "No one," he said, "had ever seen an ape pray." The answer to this profound argument is, that if any one ever did witness such a spectacle, the fact would deal the heaviest of possible blows against the theory of descent in the domain of psychology. A religious monkey would be a phenomenon impossible to explain by any scientific theory, so that—mimicry apart—if a naturalist were to see an orang outang kneel down, clasp its hands, and raise its eyes to heaven, he could only conclude that the animal was divinely—or diabolically—inspired.

[1] On reading the proof of this article, it seemed to me desirable to obtain more full information concerning this case, and, accordingly, I wrote to Mr. Tait to furnish it. The following is extracted from his reply:—

"The cat, a female, white, yellow eyes, absolutely deaf to all sounds not conveyed through solid media, was remarkably acute in the matter of sight, and singularly intelligent, being a granddaughter of my begging cat." [This was a cat which *spontaneously* adopted the habit of begging for food, and transmitted the habit to her kittens, and her kittens' kittens. I have seen one of these, now grown into a cat, which begs quite as well as any terrier; and the interesting fact is that all this family of begging kittens take to begging spontaneously, independently alike of teaching and of seeing their mothers beg.] "When in the room with Mrs. Tait and myself, and feeling a desire for milk, she first expressed that desire by peculiar cries, then by sitting in front of us and begging like her grandmother, but not in such an accomplished manner. This failing, she would go to the side of the fire-place, and, standing on a foot-stool, would pat with her hand the knob of the fire-place bell." [Of course, a cat, not having a properly prehensile hand, could not actually ring such a bell.] "This was never resisted, and as soon as she saw the bell rung, she went towards the door at which the servant would enter, and then waited in perfect confidence for the milk which she brought She did not attempt to leave the room with the servant, but waited patiently for her second coming.

"This cat was also remarkable as a fisher. She would wade into a small pond up to the shoulder and catch fish—trench, goldfish, minnows, &c.—always fond of dabbling in water."

I may here observe that cats seem to be more intelligent than dogs, at least in understanding special mechanisms. Thus it is not an unusual thing for cats, while it is an unusual thing for dogs, to ask admittance to a door by standing up on their hind legs and rattling the handle of the door with their fore-legs. Also, among the immense number of letters that I have received on the subject of animal intelligence, there is no one case narrated of a dog, while there are several cases narrated of cats jumping at knockers on street doors in order to obtain admission to their masters' houses. Similarly, I have only received one instance of a dog, while I have received several instances of cats jumping at thumb-latches for the purpose of opening the doors which the latter fasten. I myself had a cat which was constantly in the habit of entering the stables in this way. She used to spring at the handle below the latch, and, while holding on to the handle with one fore-paw, depress the latch with the other, and kick the door-post with her hind-legs in order to push the door open while she held the latch down. This complicated action can only be explained by supposing that the cat observed how her human friends manipulated a thumb-latch, reasoning that she might do likewise, and experimenting until she succeeded.

At the Zoological Gardens I have seen a small monkey hold out to me a nut to crack which was too hard for him to crack himself, and the conflict of emotions with which he held out, again withdrew, and eventually surrendered his treasure was positively painful to witness. Of course I cracked the nut, and Prof. Huxley tells me that he once performed a similar act of charity under precisely similar circumstances. Now the process of "mental reflection," which led to this surrender by the monkey of his valued property must have been both vivid and complex.

Although I have never myself observed an instance, I can have no doubt from the concurrent and independent testimony which I have received that dogs are sometimes capable of reasoning thus: Is my master out or not? When he goes out he always takes his great-coat with him; therefore I will go and see whether or not his great-coat is hanging in its accustomed place.

Lastly, I have just received a letter from the Vicar of Carn, which relates an instance of mental reflection on the part of a poodle dog that has the merit of admitting neither of mal-observation nor unconscious exaggeration. The vicar's friend—a Canon whose name I have at present no express permission to publish—went to visit a cousin, who owned the poodle dog. I will conclude by telling the rest of the story in my correspondent's own words: "The poodle, whose name is Mori, went into the dining-room with them, and kept quietly under the table till the end of lunch, when he begged for a little food, and he was given a small shred of beef. They returned to the drawing-room, while the servant cleared away, and the beef was taken into the larder. The dog did not think he had had his fair share. . . . Now, he had been taught to stand on his hind legs, put his paw on a lady s waist, and hand her into the dining-room. He adopted the same tactics with my friend the Canon, ... but the sagacious dog, instead of steering for the dining-room, led him in the direction of the larder, along a passage, down steps, &c., and did not halt until he brought him to the larder, and close to the shelf where the beef had been put." [After giving him a piece of beef, the Canon went upstairs and refused again to be led down as before.] "Finding he could not prevail on the visitor to make a second excursion to the larder, he went out into the hall, took in his teeth Canon ——'s hat from off the hall table, and carried it under the shelf in the larder, where the coveted beef lay out of his reach. There he was found with the hat, waiting for its owner, and expecting another savoury bit when he should come for his hat."

GEORGE J. ROMANES

NOTES ON THE FAUNA OF THE SOLOMON ISLANDS

At a late (January, 1879) meeting of the Linnean Society of New South Wales Mr. E. P. Ramsay, F.L.S., &c., read a paper on the Zoology of the Solomon Islands, the subject of this paper being a large collection of mammals and birds collected at Gaudalcana, Savo, and Cape Pitt by Mr. James Cockerell, a well known Australian collector. The collection was obtained from Capt. Brodie, of the schooner *Ariel*, who had made arrangements with Mr. Cockerell to collect in the islands. Among the novelties described we find two species of Monarcha: (1) *M. barbata*, with elongated black plumes from the throat, belonging to the *M. loricata* and *M. leucotis* section; (2) *M. rufocastanea*, black above, deep chestnut rufous below; (3) a Sauloprocta, *S. cockerellii*, black above and as far as the breast, which is striped with white and with the abdomen and under tail-coverts white; two species of Myiagra, (4) *M. ferocyanea*, of a beautiful clear steel-blue black above and on the throat, the remainder of the under surface white; (5) *M. pallida*, ashy blue above, white below, tail chiefly pale rufous; (6) a fly-catcher, allied to *Rhissidura rufifrons*, but distinct in being smaller and having much more rufous on the head and less on the tail, has been named *R. rufofronta*; (7) a curious little sun-bird, *Cinnyris melanocephalus*, having a black head and the remainder of the body dull olive yellow above, brighter yellow below; (8) a Pseudorectes, of a rich cinnamon colour, with whitish throat, and yellow crissum and ochre-yellow under tail-coverts, is called *P. cinnamomeum*; and (9) a Calornis of a uniform bright steel-green colour, with a sharply ridged keel-shaped culmen, but otherwise resembling *C. cantor*, is named *Calornis solomonensis*.

In addition to the new species, the collection contained some of great interest to ornithologists, particularly a beautiful series of the rare *Lorius cardinalis*, and *Halcyon leucopygia*, of which the female only was previously described. A var. of *Halcyon chloris* is also described, which differs from Mr. Sharpe's plate (Sharpe, "Monog. Alced.," pl. 87) in having the whole of the under surface rich buff, the under wing-coverts of a deeper tint. There is also a large series of *Megapodeus brenchleyi* (Gray), adults and young, and quite a number of *Dicæum erythrothorax*. Among the pigeons *Carpophaga rufigula* (Salvad.) is conspicuous from its peculiarly formed cere, also another large species allied to or identical with *C. van-wickii* (Cass.). A var. of (?) *Ptilopus viridis* is described, also *P. superba* from the same place.

The following is a complete list of the species recorded and their habitats:—

		Locality.
1.	*Astur soloensis*	Cape Pitt.
2.	*Baza stenozoa*	Gaudalcana.
3.	*Ninox* ,,	,,
4.	*Cacatua ducorpsii*	Savo.
5.	*Lorius cardinalis*	Savo and do.
6.	,, *chlorocercus*	,,
7.	*Geoffroyius heteroclitus*	,,
8.	*Eclectus polychlorus*	,,
9.	*Centropus milo*	Gaudalcana.
10.	*Cuculus taitensis*	Savo.
11.	*Chalcites plagosus* (?)	,,
12.	*Eurystomus crassirostris*	Cape Pitt
13.	*Eulobes kreffiii*	,,
14.	*Calorius metalica* (?)	Savo.
15.	,, *solomonensis*, sp. nov.	,,
16.	*Sturnoides fulvipennis*	Gaudalcana.
17.	*Graucalus hypoleucos*	,,
18.	,, ,, sp. nov.	,,
19.	*Edoliisoma* (*? plumbeum*)	,,
20.	*Tachycephala orioloides*	,,
21.	*Pseudorectes cinnamomeum*, sp. nov.	,,
22.	*Monarcha barbata*, sp. nov.	,,
23.	,, *rufocastanea*, sp. nov.	,,
24.	*Sauloprocta tricolor*	,,
25.	,, *cockerelli*, sp. nov.	,,
26.	*Rhissidura rufofronta*, sp. nov.	,,
27.	*Myiagra ferrocyanea*, sp. nov.	,,
28.	,, *pallida*, sp. nov.	,,
29.	*Cinnyris melanocephalus*, sp. nov.	,,
30.	,, *frenata*	,,
31.	*Dicæum erythrothorax*	,,
32.	*Halcyon leucopygia*, Ven.	,,
33.	,, *chloris*, var.	Cape Pitt.
34.	,, *sanctus*	Savo, &c.
35.	*Carpophaga rufigula*, Salvad.	,,
36.	,, *van-wickii*, Cass.	Gaudalcana.
37.	*Ptilopus viridis*, var.	,,
38.	,, *superbus*, Temm.	,,
39.	*Chalcophaps chrysochlora*, var.	,,
40.	*Macropygia* ,,	Savo.
41.	*Megapodius brenchleyi*	,,
42.	*Butoroides javanica*	,,
43.	*Herodias garzetta*	,,
44.	*Sula personata*	,,
45.	*Sterna bergerii*	,,
46.	,, *gracilis*, Gould	,,

In addition to the birds Mr. Cockerell obtained in quantity two species of Pteropus, two varieties or perhaps species of Cuscus, a species of Harpyia, a new Chiero-

pteruges, and a Macroglossus, also a species of Scotophilus, probably *S. nigrogriseus*, Gould.

The fishes were not numerous, but some interesting species were obtained, respecting which the Hon. Wm. Macleay read some remarks which will be published in due time.

The insects, about fifty species, will also we hope be taken up by Mr. Macleay. Among the spiders are some very interesting forms, apparently quite new.

The collection of birds numbers about 350 specimens, the mammals about 120. Spirit specimens about 100.

We believe a large portion of this fine collection has been secured by the curator, Mr. E. P. Ramsay, F.L.S., for the Australian Museum.

THE SORTING DEMON OF MAXWELL[1]

THE word "demon," which originally in Greek meant a supernatural being, has never been properly used to signify a real or ideal personification of malignity.

Clerk Maxwell's "demon" is a creature of imagination having certain perfectly well-defined powers of action, purely mechanical in their character, invented to help us to understand the "Dissipation of Energy" in nature.

He is a being with no preternatural qualities, and differs from real living animals only in extreme smallness and agility. He can at pleasure stop, or strike, or push, or pull any single atom of matter, and so moderate its natural course of motion. Endowed ideally with arms and hands and fingers—two hands and ten fingers suffice—he can do as much for atoms as a pianoforte player can do for the keys of the piano—just a little more, he can push or pull each atom *in any direction.*

He cannot create or annul energy; but just as a living animal does, he can store up limited quantities of energy, and reproduce them at will. By operating selectively on individual atoms he can reverse the natural dissipation of energy, can cause one-half of a closed jar of air or of a bar of iron to become glowingly hot and the other ice-cold; can direct the energy of the moving molecules of a basin of water to throw the water up to a height and leave it there proportionately cooled (1° Fahr. for 772 feet of ascent); can "sort" the molecules in a solution of salt or in a mixture of two gases, so as to reverse the natural process of diffusion, and produce concentration of the solution in one portion of the water, leaving pure water in the remainder of the space occupied; or, in the other case, separate the gases into different parts of the containing vessel.

"Dissipation of energy" follows in nature from the fortuitous concourse of atoms. The lost motivity is essentially not restorable otherwise than by an agency dealing with individual atoms; and the mode of dealing with the atoms to restore motivity is essentially a process of assortment, sending this way all of one kind or class, that way all of another kind or class.

The classification, according to which the ideal demon is to sort them, may be according to the essential character of the atom; for instance, all atoms of hydrogen to be let go to the left, or stopped from crossing to the right, across an ideal boundary; or it may be according to the velocity each atom chances to have when it approaches the boundary: if greater than a certain stated amount, it is to go to the right; if less, to the left. This latter rule of assortment, carried into execution by the demon, disequalises temperature, and undoes the natural diffusion of heat; the former undoes the natural diffusion of matter.

By a combination of the two processes, the demon can decompose water or carbonic acid, first raising a portion of the compound to dissociational temperature (that is, temperature so high that collisions shatter the compound molecules to atoms), and then sending the oxygen atoms this way, and the hydrogen or carbon atoms that way; or he may effect decomposition against chemical affinity otherwise, thus: Let him take in a small store of energy by resisting the mutual approach of two compound molecules, letting them press, as it were, on his two hands, and store up energy as in a bent spring; then let him apply the two hands between the oxygen and the double hydrogen constituents of a compound molecule of vapour of water, and tear them asunder. He may repeat this process until a considerable proportion of the whole number of compound molecules in a given quantity of vapour of water, given in a fixed closed vessel, are separated into oxygen and hydrogen at the expense of energy taken from translational motions. The motivity (or energy for motive power) in the explosive mixture of oxygen and hydrogen of the one case, and the separated mutual combustibles, carbon and oxygen, of the other case, thus obtained, is a transformation of the energy found in the substance in the form of kinetic energy of the thermal motions of the compound molecules. Essentially different is the decomposition of carbonic acid and water in the natural growth of plants, the resulting motivity of which is taken from the undulations of light or radiant heat, emanating from the intensely hot matter of the sun.

The conception of the "sorting demon" is purely mechanical, and is of great value in purely physical science. It was not invented to help us to deal with questions regarding the influence of life and of mind on the motions of matter, questions essentially beyond the range of mere dynamics.

The discourse was illustrated by a series of experiments.

[1] Abstract of Lecture at the Royal Institution, Friday, February 28, 1879, by Sir William Thomson, LL.D., F.R.S.

PAOLO VOLPICELLI

THIS eminent Italian physicist, whose death we recently recorded, was born at Rome on January 8, 1804. He lost his mother a few days after his birth; his father was Prof. Alexander Volpicelli, a member of the Medical College of the Roman University. Paolo was educated at the college of Veroli and the University of Rome, where, in accordance with the wish of his father, he commenced the study of medicine, but abandoned it after the first year, declaring that medicine was not a science. Of his own accord he applied himself seriously to the course of mathematical philosophy, and four years later received the degree of doctor *ad honorem* in that faculty. It should be mentioned that doctorates *ad honorem* are given to only two students each year, and Volpicelli's fellow-doctor was the eminent Professor Tortolini, who followed the same course. Before leaving the University his professors recommended him to the Government for a scientific position. In fact, Prof. Morichini wished to name him his successor to the Chair of Chemistry in the University of Rome, but Volpicelli preferred to succeed Dr. Barlocci, Professor of Experimental Physics in the same University, and in 1845, on the death of Barlocci, became titular professor. Volpicelli occupied this chair till 1873, when he was appointed Professor of Mathematical Physics in the same University. In 1851 he was made a member of the Philosophical College, an honour accorded to only twelve professors of the University of Rome. Besides his position at this University, Volpicelli also filled that of Professor of Mathematical Physics at the Roman Seminary, taught geometry to the pupils of St. Michael's Hospital, and founded at Rome the special School of Artillery, of which he was director for thirty years.

When Pope Pius IX. revived the celebrated and historical Lincei Academy in 1847, Volpicelli was appointed secretary, a post which he held for thirty years, when, as his health was failing, the academicians made him secre-

tary *emeritus*. By his tact and energy at the time of change of government at Rome, he was enabled to save the Archives of the Academy, of which during his lifetime he was one of the most active members.

Volpicelli was well known abroad, and the Emperor of Brazil when in Rome spent some time with the professor, and conferred upon him the grade of officer of the Imperial Order of the Rose. Volpicelli travelled much, and in 1850 he made a long stay in England, where he made the acquaintance of Faraday, Brewster, Airy, Murchison, Sabine, Panizzi, Wheatstone, and others, with whom he afterwards continued to correspond. In France and Switzerland also, he was the friend of the most eminent men of science.

Volpicelli was an energetic worker in his favourite field of electrical research, and to the last maintained with vigour the theory of Melloni, at which he had worked for twenty years. The papers and other works published by Volpicelli were very numerous; no less than 270 are enumerated in a list published by the Academy dei Lincei. Although he is chiefly known by his researches in electricity, these papers show that he did much other work in various departments of mathematics and physics. Volpicelli's papers will be found mainly in the *Atti de l'Accademia dei Lincei*, and the *Comptes Rendus* of the Paris Academy. Very few of them have, however, been translated into English, a circumstance which must be regretted for the sake of English scientific men, to many of whom Volpicelli's researches are known only by name. He died calmly on April 14, having been visited shortly before his death by the Pope's brother, Cardinal Pecci.

AN AMERICAN SUGGESTION

WE have occasionally noted in these columns the formation of mathematical societies, and we have ventured, in our ignorance, to suggest that as a consequence of the great advance in the cultivation of mathematics recently made by our American cousins, the time had come for the formation of an American or (following the analogy of associations nearer home) of a Baltimore Mathematical Society.

A short account of the *Proceedings* at the fifth meeting of the Lehigh Mathematical Society—recorded in the *Bethlehem Daily Times* (Pa.) for March 17—may interest kindred societies on this side the Atlantic, and serve to show that the transactions of such learned bodies may contain "something of importance and profitable (*sic*) to the general reader."

It appears that in order to remedy the defects in the art of surveying, it has been made imperative (so says Mr. S. R. Vay, Civil Engineer, the reader of the paper[1]) by the American legislature that "each county should at its own expense and on its own land, plant, or erect, two monuments of stone, so that the straight line between them should be an exact and due meridian, or north and south line; in order that thereby surveyors, by setting a compass on the one monument, and pointing it to the other, might readily ascertain the deviation or variation of the magnetic needle, and thus be prevented from committing errors in the determination of property lines and landmarks." His soul was much stirred at the neglect of this "scientific duty." It seemed to him that "the scientists of the valley ought to urge, with no uncertain voice, the erection of such or similar monuments. With but little extra expense they could easily be made to interest and to educate, as well as to serve the purpose designed by the legislature. Imagine, for instance, two beautiful granite monuments standing in appropriate situations on the spacious ground of Lehigh University, one mounted with a sun-dial, and the other with an anemometer. On one of them should be cut in plain letters the latitude, longitude, and elevation above the sea of that exact spot. On the other should be recorded a statement of the mean annual temperature and rainfall of the valley. The axis of the sun-dial would not only point to the steadfast pole, but be parallel to the earth's axis; it could, indeed, be furnished with a hoop or circle, to represent the equator, and with others to represent the meridians of Greenwich, Washington, and Bethlehem; a circle to indicate the ecliptic would not be difficult to add, which, by properly constructed clock-work should be always kept parallel to the real ecliptic itself. Thus all who might pass that way would be interested in reading the inscriptions and observing the time, and many would be instructed in the science of astronomy. Even to students it would be of benefit in lightening their mental struggles to grasp, conceive, and understand the idea of the ecliptic circle and the ecliptic plane."

[1] Touching first upon the necessity of preserving boundaries and upon the methods employed by the ancients; tracing the word geometry to its source, and relating how the Egyptians were puzzled to find their landmarks, he then passed on to the discovery of the magnetic needle, and the perplexity caused to country surveyors by the deflection of the same.

In the discussion which followed, the President doubted the wisdom of the legislature, and thought the better way would be to require higher qualifications from surveyors.

Dr. H. E. Licks inquired the expense of such a sun-dial as Mr. Vay had described.

Mr. A. S. Tronomy said "it was usual to consider the ecliptic as a fixed plane when illustrating the yearly motion of the earth. When considering the daily rotation, however, he could see that Mr. Vay's plan had some advantage."

The next paper was by Prof. Ternion, "On the consequences which would result from denying or reversing the tenth axiom of Euclid." The argument, we learn, was "elaborate and profound, being exemplified by long formulas written on the blackboard." He showed that "if the properties of matter or space were such that the axiom became false, a knot could not be tied in a string, that a hollow rubber ball could be turned inside out without tearing or stretching, and that no satisfactory system of paper or silver money could be employed."

Mr. K. M. Puter considered the paper as an example of mathematical analysis, one of very great value, but he considered it fortunate that we cannot practically reverse the axioms of geometry. "If we could, the results would be disastrous." Our notice of the *Proceedings* at this interesting meeting have extended to some length, but they may be suggestive of matter for societies on this side of the world. We cannot close, without alluding to another feature, and that is the subsequent proceedings (unscientific) before the members separated.

Crackers and cheese were brought forward and the knot untied by the Secretary "without denying any axiom whatever." "The mathematical joke and the hearty laugh were heard," and, tell it not in Gath, they sang a song. Of a Mathematical Society not a hundred miles off, the first President wrote, "not a drop of liquor is seen at our meetings, except a decanter of water; all our heavy is a fermentation of symbols; and we do not draw it mild. There is no penny fine for reticence or occult science; and as to a song! not the ghost of a chance."

THE STANDING STONES OF CALLANISH

THE object of the present paper is to describe the standing stones of Callanish, Island of Lewis, accompanied by notes of such measurements as the author was able to take during a somewhat hurried visit to these very interesting memorials of the early inhabitants of our islands.

Leaving the town of Stornoway, we soon find ourselves amongst great tracts of moorland, with sheets of water large and small on all sides. The deep black peat is being cut and piled up into stacks, when, after being dried, it will serve for the winter's fuel. The peats in the Lewis

are broad and thin, and not so brick-shaped as those on the mainland further south. All around wears a sombre aspect. Miles and miles of bog and moorland, without tree or bush to break the long undulatory lines which rise and fall like the waves of the sea.

At length, as we reach the top of a slight rise, we see before us the object of our visit, the stones appearing so thickly clustered together on the rising ground on which they stand, as to suggest the likeness to a cemetery. Leaving the vehicle a little beyond the sixteenth mile-

Plan of General Arrangement of Group.

stone from Stornoway, we ascend by a roughly causewayed roadway which leads from the main road to the top of the low hill upon which the stones are placed. On a closer inspection it is found that the general outline is cruciform, and at or near the intersection of the cross limbs is placed the largest stone, whilst around is a circle of tall stones. The stones are rough, and appear only to have received such dressing as would bring them to a suitable shape for erection; they are composed of the rock of the island, the Laurentian gneiss, which, in geo-

View from North-East.

logical record, is the oldest known. In colour it is greyish, with occasional flesh-coloured patches. The stones are monoliths, and are all upright.

The upper parts of the stones are covered with a greyish green lichen, the lower parts being comparatively bare. This is accounted for by the fact that a number of years ago the proprietor of the island caused the peaty ground around to be removed, which showed that the height was much greater than had at first appeared; the parts thus recently disclosed have not the heavy coating of lichen which the upper parts have; the line separating the two parts is very marked. From this the great age

of the stones may be inferred, as there has been an accumulation of peaty soil of about five feet deep.[1]

From a careful inspection of the stones the author found the number to be forty-eight. (The driver's remark on being asked the number was that they could not be counted over by different people and made the same.) The highest stone is about 16 feet, and the stones forming the circle are next to the central one in height, varying from about 8 feet to 11 feet. The others vary from about 7 feet to about 4 feet.

The longer limb of the cross is composed of two rows of stones placed about 27 feet apart, there being ten stones on the west side and nine on the east side. This is a very distinct feature in the arrangement, as there is thus an avenue leading to the circle. The circle consists of thirteen stones, and the western and eastern cross arms have each a single line of four stones, whilst the southern limb is composed of six stones; the whole with the central stone and one outside and close to the circle makes forty-eight. The general arrangement will be more readily understood from the accompanying plan, which is drawn approximately to scale. From careful observations with a pocket compass, the general bearing of the northern limb was found to be 30° to east of magnetic north; it was also found that, when a line was projected from the flat side of the endmost southern stone, it cut exactly the end stone of the western side of the northern limb; the latter stone measures about 11 feet in height. If the compass variation be estimated at 25° west (the latitude is about 58° 12′ north), it appears that the main axis of the group lies about 5° to *east* of true or polar north. Several of the stones besides the one already mentioned appear to have a *directive* tendency, notably the one next the circle in the eastern side of the northern limb; this stone, both from its pointed shape and flat form, leads the eye to the centre of the circle. The whole series, indeed, are arranged with their narrow faces pointing in the line of setting; this is easily noticed, as the stones are generally flat, thin, and slab-like. The circle stones have their broadest faces turned to the centre of the circle. The great stone is situated at or near the centre of the circle; it measures about 16 feet in height, with a breadth at bottom of 5 feet, at middle of 4 feet, and upper part 3 feet 6 inches; its thickness is 1 foot; its flat side faces the east. This stone must weigh about six tons.

The general dimensions of the group are as follows:—

Extreme length, 128 yards; length of northern limb, 85 yards; diameter of circle, 14 yards (this measurement is in a north and south line; from east to west the measurements gave 13 yards, so that the figure is slightly elliptical); length of southern limb, 29 yards; extreme breadth, 44 yards; length of western arm, 13 yards; length of eastern arm, 18 yards. The whole figure roughly resembles the Iona cross in outline. In or near the centre of the circle there is a hollow, roughly rectangular on plan, measuring about 7 feet long, the breadth at centre being 6 feet, and at ends 5 feet, narrowing, however, at the eastern end, so as to form a kind of channel leading outwards. The sides of this hollow are built of small stones, and four large stones are placed so as to break up the whole into two chambers. The direction of length of this hollow is east and west; the tall central stone already described being situated near to and facing its western end. It is said that a stone cover was found upon this hollow when first discovered. The hill upon which the stones are placed slopes downwards to the north; the ground on which the cross arms are placed is about level.

[1] It is difficult to get reliable data as to the growth of peat-moss, but taking about 200 years to the foot, a depth of 5 feet would infer a period of about 1,000 years since the peat commenced to form. In Black's "Guide" it is stated that the stones rest on a causewayed base. As there was no trace of this at the time of the author's visit, seeing that there was a vegetable growth all around, some data as to rate of growth of the peaty soil might be got, as it is about twenty years since the excavation of the peat took place.

Another circle of tall stones still stands about a mile to eastward, from which it appears that the peat has been recently removed.

From an examination of the stone circles of Arran, the late Dr. Bryce found that stone cists in some cases existed at the centres of the circles, and that the longer lengths of these cists, as also the longer axis of one elliptically-shaped series of stones, were all lying about north and south, or inclining rather to east of north.

In the Smithsonian Report for 1876 there is a description of mounds and lines of stones in Guatemala, the long sides and directions of which were about 5° to west of magnetic north; they vary from 2 feet to 6 feet in height. This would leave, after allowing for the easterly variation of the compass there, a probable direction of 5° or 10° to east of true or polar north. A certain similarity, therefore, appears to exist in the setting out of these groups, with a tendency to a direction east of north.

The country people called the place Callanish, not Callernish, as sometimes given, the meaning of the former name having been defined as "place of assembly for worship," whilst the latter is given as "bleak headland."[1] The title Fir Bhreige, or false men, is sometimes given to the group, from the apparent motion of the stones as the spectator changes his position when viewing them from a distance.

The erection of such circles as that of Callanish has been popularly attributed to the Druids, and according to this theory the Callanish circle would have been a religious meeting-place. Again, it has been supposed that they were tombs of warriors, and may have been erected by the early Norse rovers. Others look upon such groups of stones as places for judicial meetings, which might have been accompanied by religious ceremonies. From some recent scientific investigations at Stonehenge it appears likely that the stones there were erected for astronomical purposes.

The general impression which one gets from standing amongst the Callanish stones is that the long avenue was intended as an approach from the not far distant shore for a large body of people, who would thus converge towards the central circle.

W. J. MILLAR

[1] See Smith's "Lewsiana."

OUR ASTRONOMICAL COLUMN

BIELA'S COMET IN 1879.—There have been suggestions as to sweeping ephemerides for the recovery of one or other portion of the disintegrated comet of Biela in the present year. It is not, however, easy to decide in what manner, or rather upon what assumptions, calculation can be brought to bear with the greatest chance of success. We know that in 1852 the observed positions of the two nuclei were such that they could be accurately connected with similar positions at the preceding appearance in 1846, by the application of the perturbations from known causes in the interim, and it is also certain that neither of the nuclei was in the calculated position at the next return but one in 1866, there having been no chance of finding the comet in 1859, from proximity of its geocentric track to the sun's place. In 1865-6 the comet was diligently sought for in and around the position it should have occupied by the elements of 1852, brought up to 1866 by the application of planetary perturbations during the two revolutions, with some of the most powerful instruments in our observatories, including the refractors at Pulkowa and Copenhagen. D'Arrest, after long search, was convinced that the comet, speaking collectively, could not have passed its perihelion within many days of the time predicted. The conclusion was inevitable that perturbation from some unknown cause must have taken place between 1852 and 1866, and that all clue to the future movement of the comet was for the time lost. In 1872 endeavours to find

the comet near its old track were equally unsuccessful, and it was not till the grand meteoric shower on the evening of November 27 in that year that further light was thrown upon the subject. As is well known, the meteors of that great shower were found to be moving in an orbit sensibly identical with that of Biela's comet in 1866. Intersecting, or at least passing very near to the earth's orbit on November 27, the comet must have been descending to a perihelion passage a month later, or about December 27·6; such at least would be the date when the meteoric shower would arrive at its least distance from the sun. In this fact appears the only ground upon which we can now work to obtain an idea of the probable position of the comet in the present year. If we apply Dr. Michez's perturbations from 1852 to 1866 to the late Prof. Hubbard's elaborately-determined elements of the south-following nucleus in 1852 (assumed to be identical with the principal comet in 1846), we find the following orbit for 1866:—

Longitude of perihelion	109° 39′ 48″	Mean equinox
,, ascending node ...	245 43 42	January 27.
Inclination to ecliptic	12 22 3	
Angle of excentricity	48 46 19·35	
Mean daily motion	529″·9157	
Revolution	2445·67 days.	

And bringing up the longitudes to the equinox of 1879 we have the following heliocentric co-ordinates to be combined with the X, Y, Z of the *Nautical Almanac* in the preparation of sweeping-ephemerides on different hypotheses as to time of arrival at perihelion:—

Time from perihelion.	*x.*	*y.*	*z.*
−50 days ...	+0·8145 ...	+0·7263 ...	+0·4119
40 ,, ...	0·6150 ...	0·7914 ...	0·3916

If the meteoric cloud of November 27, 1872, was moving in the orbit given above, a revolution counted from December 27·6 in that year will bring us to about September 8, 1879, as the epoch of next perihelion passage. Assuming September 7·5 we should have the following sweeping-line for that date:—

Time from perihelion.	Right ascension.	North declination.	Distance from earth.	Intensity of light.
0 days ...	140°·2 ...	10°·8 ...	1·66 ...	0·47
−20 ,, ...	125·9 ...	17·4 ...	1·42 ...	0·57

It may, however, be regarded as by no means improbable that the perihelion passage of the body which caused the shower of meteors may take place much later, and a very close and extended search will be required.

Sweeping-ephemerides to the extent desirable would occupy too much space here, but they will be easily prepared in the manner indicated from the above co-ordinates.

It is impossible not to admit the justice of a remark made by M. Otto Struve at the Stockholm meeting of the German Astronomical Society, when urging further attention to this comet: "Kein Comet gebe mehr Ansicht, über die Natur der Cometen im Allgemeinen etwas zu erfahren, als der Biela'sche;" and if due preparation be made this year for an exhaustive examination of the heavens in those regions where it is possible any portion of the comet may be found, further light may be thrown upon what yet appear the mysterious agencies which have affected its constitution and motions.

GEOGRAPHICAL NOTES

IN the place of Prof. Geikie's lecture on geographical evolution which was promised for this month, the June number of the Geographical Society's monthly periodical contains the anniversary address by Mr. Markham on the progress of geography. This is followed by a short paper on the "Mardian Hills and the Lower Indravati in the Bustar Dependency," contributed by Capt. T. H. Holdich, R.E., who also furnishes a sketch-map of the region. As regards quantity, at any rate, the geographical notes show a great improvement on previous numbers, and many of them supply information of considerable interest. Attention may be especially called to Mr. Keith Johnston's remarks on the employment of elephants in African travel, and regarding his own movements, Russian topographical labours in the Kirghiz Steppe and in Turkistan, the Russian Trans-Caspian territory, recent topographical survey by the Russians from the Oxus to Herat, new maps of Afghanistan, and a singular cave-formation in Queensland. There is also a good summary of Lieut. Wheeler's survey work in Oregon in 1878, based on an account drawn up by Mr. T. W. Goad, who was himself an active partaker in the work. Under the head of "Proceedings of Foreign Societies," we find a report of the Inter-Oceanic Canal Congress up to May 23. The last thirteen pages of the number are occupied by notes on new books and maps.

MR. J. F. BROUMTON, the agent of the China Inland Mission at Kweiyang-fu, in the Kweichow province, recently accompanied Mr. Cameron, on his way from Yünnan to the sea-board, as far as Kweilin-fu, in Kwangsi. Their route lay through the regions occupied by the Miao-tsze, or aboriginal tribes, who are very numerous in the south-east of Kweichow, and practically independent of the Chinese. Mr. Broumton visited a place called Pa-tsia, near which there are many Miao-tsze, but they are very shy and do not mix with the Chinese, only coming to the town on market-days to buy cotton, cloth, salt, &c. Their villages consist of mud cottages, usually hidden among trees and situated in places among the hills, which are difficult of access. From what he saw, Mr. Broumton thinks that the Miao-tsze are thrifty and industrious, for their land seemed well cultivated and the people well clothed. There is another interesting class of people in the Kweichow province, viz., the Tsung-kia-tsze, who, it is thought, originally emigrated from Hunan and Kiangsi, and in course of time intermarried with the Miao-tsze. Now they are a distinct class, speaking a language differing from both the Chinese and the Miao-tsze. Like the latter, they do not bind their girls' feet, and they are described as a sturdy, hardy race and thriving agriculturists.

IN the annual statement of the British Museum, just presented to Parliament, we find a report by Mr. Major on the department of maps, charts, plans, and topographical drawings. We do not learn very much as to the nature of the accessions made during the year, but Mr. Major particularises a photographic reproduction of a hydrographical chart on parchment (dated 1385) in the Royal Archives at Florence, comprising the Atlantic as far as Cape Bojador, then the furthest point of geographical discovery southwards, to Syria and the Black Sea, on the east. On this chart, which is earlier by half a century than the effective discovery of the Azores by Diego de Sevill and other navigators, we find the islands of San Miguel and Santa Maria laid down, but with an illegible description, while the islands of San Jorge, Fayal, and Pico are described as Insule de Ventura and Columbia, and Terceira is named Insula de Brazi, so called from the Brazil wood with which it abounded, thus preceding its famous namesake in South America by a century and a quarter. The chart bears the following epigraph:—

"Gulielmus Solerij civis Maioricarum me fecit anno a Nat. Domini Mccclxxxv."

As considerable difficulty is often found in fixing the position of places in the interior of Australia, the following note of the distance in miles from Adelaide of each station on the overland telegraph line which terminates at Port Darwin on the northern coast, will be found useful:—Beltana, 355; Strangway Springs, 565; Peake, 636; Charlotte Waters, 804; Alice Springs, 1,036; Barrow's Creek, 1,207; Tennant's Creek, 1,354; Powell's Creek, 1,467; Daly Waters, 1,605; River Katherine, 1,771; Pine Creek, 1,825; Yam Creek, 1,854; Southport, 1,934; Port Darwin, 1,973. Considerable progress is being made with the trigonometrical survey of South Australia. We also learn that an exploring expedition from Queensland has just completed a flying survey across the northern portion of both colonies, large tracts of which are still practically unknown.

Excellent news from Abbé Debaise has arrived in Marseilles.

The Inter-Oceanic Congress has adopted, by 98 votes against 8, the proposal in favour of cutting the canal through the Isthmus of Panama, by the Bay of Limon, to Panama.

Dr. Miclucho Maclay, the Russian explorer, with an Italian, Chevalier Bruno, and Capt. Leeman, have sailed from Sydney for New Guinea, in the American schooner *Laddie*, F. Caller, chartered for a twelvemonth's cruise. 2,500*l*. has been spent on the equipment. The expedition is intended to be both scientific and commercial. New Caledonia, New Britain, and other islands are to be visited.

The first part of Dr. Nachtigal's new work: "Reisen in Afrika," comprising his journey across the desert to Bornu, is about to be published by Messrs. Wiegandt, Hempel, and Parey, Berlin.

A telegram from Gordon Pasha to the Italian Geographical Society, announces that Capt. Martini, the leader of the Italian expedition which is going to assist the Marchese Antinori, has obtained permission to enter Abyssinia, that he had left Œdowa, and had landed at Massanah.

THE FIRST OBSERVATIONS OF SUN-SPOTS

At p. 284 of Nature, vol. i., the following paragraph occurs:—

"Dr. Kirkwood commences by reminding us that the most ancient observations of sun-spots of which we have any record, are those of the Chinese in the year 321 A.D.; the first notice of their detection by Europeans being found in the *Annals* of the Frankish Kings. A black spot, according to Adelmus, was seen on the sun's disk March 15, 807, and continued visible eight days. Similar phenomena were again observed from May 28 to August 26, A.D. 840. The year 1096 was also signalised by the appearance of spots so large as to be visible to the naked eye. The next date, in chronological order, is that of 1161, when a spot was seen by Averröes. Finally, on December 7, 8, and 16, 1590, 'a great blacke spot on the sunne' was observed at sea by those on board the ship *Richard of Arundell*. The foregoing are, we believe, the only undoubted instances in which these phenomena were observed previous to the invention of the telescope."

During the winter of 1877-78 the late Mr. Mayers, Chinese Secretary of the British Legation in Peking, purchased on behalf of the British Museum a large Chinese Encyclopædia, comprising 5,020 volumes, and containing the most valuable information, historical, literary, and scientific. Unfortunately, however, its records end with the *Ming* dynasty, A.D. 1628. Whilst preparations were being made for its shipment to London, a sub-section of this immense work, entitled "Natural Phenomena," was placed at my disposal for purposes of research. I resolved to confine my attention to obtaining records (1) of the droughts and famines that had visited China, and (2) of the sun-spots observed by the Chinese.

The records of the droughts and famines are most minute. The years, months, and districts affected are given in detail.

With regard to sun-spots[1] [black spots on the sun[2]] I found that from B.C. 28 to A.D. 1617 fifty-six observations were recorded, and that ten other observations of what I have translated sun-shadows,[3] four of them prior to the first sun-spot observation, were mentioned. These observations are exhibited in the annexed table, from which it will be seen that undoubted sun-spots were visible in China on three occasions previous to the year A.D. 321—the date given by Père Mailla in his "Annales de la Chine"—namely, in the years A.D. 301, 302, and 307. The solar phenomena observed in 807 and 840 are also mentioned in the Chinese record.

The remarks regarding the apparent sides of the sun-spots, &c., are literal translations of the Chinese text.

ALEXANDER HOSIE

British Consulate, Canton, April 1

NATIONAL WATER-SUPPLY EXHIBITION

HYDE PARK and Trafalgar Square experiences have very plainly shown that the simplest way to induce a clamorous populace to forget what they fancy they want, is to let them hold their meetings and pass resolutions. It is a matter of such very small exertion to hold up a hand in favour of a resolution compared with taking any personal trouble to see that any steps are taken towards carrying it into effect. Human nature is only in certain phases influenced by a man's occupation, and whether resolutions are passed by "labourers" or by "professional gentlemen," they stand much the same chance of being forgotten after the press has recorded that they have been passed. Last year the Society of Arts in loyal response to the request of its Royal President, held a conference to discuss the water-supply question. After two days' work a resolution was carried urging that a small scientific commission should be appointed to collect information and suggest further inquiries on the subject. Twelve months elapsed and a few days ago another conference was held, when it was made known that the only step taken with regard to that resolution was that just before the Conference it had reached the Lords of the Treasury. Last year the Society directed that a *résumé* and sort of index should be made of what had been done by Parliamentary inquiries and official reports with regard to water-supplies, and the result was a volume called "Notes on Previous Inquiries," which, though very incomplete, may serve as a basis for a larger and more comprehensive work. The very fact of the imperfections in these notes showed to those more immediately connected with their compilation the need of enlisting wider sympathies if anything of real value was to be printed. A letter in the *Times* of April 14 of this year mentioned that although the notes had been published for many months, "not a single word" had been sent in response to the request printed on the back of the title-page that suggestions or corrections should be sent to the secretary. The idea was then suggested of founding a permanent free museum for the purpose of keeping before the public mind those subjects, apart from the question of low rates only, which should be considered in arranging water-supplies. It was decided that a temporary exhibition should be first tried as an experiment and after some difficulties in finding it a *locale*, the management of the Royal Aquarium kindly arranged for the use of the south gallery for the purpose. This exhibition is now open and a handbook is issued. It is marked "under revision," and on the title-page attention is appropriately drawn to the fact that it is the *first* public exhibition of the kind.

This handbook, we are told, has been drawn up under great disadvantages in many ways. One great difficulty has been that the exhibition has grown beyond what seemed at first likely to be its extent, and entries for the handbook have come from time to time, though but slowly. This was, perhaps, to be expected in an exhibition, the first of its kind, which was, therefore, to some extent, an experiment; and that many should hold aloof till success was assured was but natural. Although this gradual growth is a matter that must be a satisfaction to those interested in spreading a knowledge of what a study of water-supply means, it has entailed much unexpected labour on the part of the management.

Among those who have helped in the scientific sections are—Col. Beaumont, M.P., Col. Bolton, Baldwin Latham, F.R.S., J. G. Symons, F.R.S., J. E. Gardner, F.S.A., Dr. Granville Cole, Prof. Wanklyn, Prof. G. Bischoff, W. Cooper, Joseph Lucas, F.G.S., A. T. Atchison, M.A., C. E. De Rance, H.M.G.S., F.G.S., J. B. Jordan, F.G.S.

The comprehensive scope of the exhibition may be gathered from the following list of the sections into which it is divided :—

Section I.—Rainfall.
" II.—Geology and Hydrogeology.
" III.—Collection and Storage of Water.
" IV.—Suggested Development of Supplies.
" V.—Distribution of Water.
" VI.—Water Examination.
" VII.—Filtering.
" VIII.—Hardness.
" IX.—Disease.
" X.—Antiquarian.
" XI.—Pollution.
" XII.—Literature.
" XIII.—
Class 1.—Appliances for Cooling Water in Summer.
" 2.—Waters artificially Aërated.
" 3.—Miscellaneous.

A scientific committee has been formed to draw up a report on the exhibition, especially to point out what defects should be remedied in future exhibitions of the kind, and it is announced that next week "demonstrations" will be given on the sections embracing scientific apparatus.

NATURAL SCIENCE DEGREES AT OXFORD

MANY of our readers have no doubt noticed the scheme which some *soi-disant* "friends of science" in authority at Oxford have brought forward professedly in the interests of science. One of the prime movers in the new scheme for the creation of B.N.S. and M.N.S. degrees is Canon Liddon, who insists that for the degree of Arts Greek shall be indispensable, but for the inferior degrees in science may be dispensed with. Since the meeting of congregation at which the scheme was discussed, there has been much correspondence in the *Times* on the subject, the letters of most importance being those of Canon Liddon and Prof. Odling. The former in his correspondence professes to have the interests of natural science purely at heart in the creation of the new degree, which, he maintains, would give facilities to a much wider class to obtain the stamp of the University than if Greek were insisted on, as he maintains must be the case with *the* degree of the university. The opposition of Prof. Odling and those who think with him, is not to the creation of a degree in natural science, but to any course that would degrade it in public estimation. He urges on the university the desirability of framing such statutes in reference to any such degree, as shall assure it a high place in general estimation, and shall more especially obtain for it the approval and sympathy of the cultivators of natural science. He considers it important to this end that the possession of a degree in natural science shall imply on the part of the student, first, general cultivation, and second, special knowledge in some branch of science. But according to the proposed innovation, if

such general cultivation is based on classical studies, the student cannot get the new degree, but must take the Arts degree, which *quoad* natural science must be held to be an inferior degree. But he shows that by the proposed statute the science graduate need know little of natural science, as he may take his degree in the School of Mathematics; thus he shows a degree in natural science might be confined to those who had never got beyond its rudiments; why, then, he asks, does not Canon Liddon propose a new degree in mathematics, and thus "assign one set of students a new decoration which will honourably represent their real attainments." Prof. Odling shows that many of those who in the debate insisted on Greek being necessary to a degree in Arts, admitted it was not necessary to a liberal education; and thus, a degree in Arts must be held as something different from a certificate of liberal education.

"If, then, it be once conceded, and the concession was made without hesitation, that Greek is not essential to a liberal education, and that the studies of mathematics and natural science and modern languages do constitute liberal studies, how is it possible," Prof. Odling asks, "to refuse a degree in Arts to those who, in addition to considerable acquaintance with Latin and German, are possessed of special attainments in either mathematics or natural science, and also of not inconsiderable attainments in the alternative one of these two subjects."

According to the proposed statutes, Prof. Odling concludes, the new natural science degree, while it will certify to an ignorance of Greek, will not certify to a knowledge of natural science.

In reply to Prof. Odling, Canon Liddon asserts that Greek "is an instrument of unrivalled delicacy for effecting the general training of the mental powers, and especially for imparting to them those habits of exactness and refinement without which it is impossible to reach the higher characteristics of an educated man." "An education which excludes Greek," he maintains, "is certainly less liberal than an education which insists on it." For the liberal education of the highest order, only, according to Canon Liddon, to be attained by learning Greek, the highest honour of the University should be reserved; to a lower degree of liberality attained through means of natural science, even with a training in Latin or German, an inferior honour can only be conceded.

At present we give these arguments and assertions without comment.

NOTES

An influential committee has been recently formed for the purpose of obtaining subscriptions to procure a portrait of Dr. W. B. Carpenter, F.R.S., to be presented to the University of London as a permanent memorial of his long and assiduous labours on behalf of that institution. We need not say one word to commend the object of the "Carpenter Memorial Committee" to the practical consideration of our readers; Dr. Carpenter's services to science and to the London University are so well known, that we are confident the proposal of the Committee will meet with a satisfactory response. Earl Granville is chairman of the Committee, which contains many names eminent in science, as well as in other departments. The honorary treasurers are Sir John Lubbock and Dr. William Smith, to either of whom cheques and post-office orders should be made payable. Subscriptions should be sent to either of the honorary secretaries, J. G. Fitch, 5, Lancaster Terrace, Regent's Park, or G. Knight Watson, Society of Antiquaries, Burlington House.

We take the following from the *Gardeners' Chronicle*:—"The *London Gazette* of the 24th inst. announces that Her Majesty has been graciously pleased to confer the appointment of Companion of the Most Distinguished Order of St. Michael and St. George on George Bentham, Esq. While we rejoice to find some official recognition made of the life-long services to botany rendered by Mr. Bentham, we regret that such recognition has been so tardy, and that it is so inadequate. Such distinctions are not as a rule highly prized by scientific men, inasmuch as they are not specially appropriate to them; but if paid at all, they should be prompt and adequate." Baron von Müller, Government Botanist of Victoria, has been promoted to the dignity of Knight Commander of the same order, and a well-deserved knighthood has been bestowed on Mr. Henry Bessemer.

We regret to record the death at Halifax, Nova Scotia, of Prof. John James Mackenzie, at the age of thirty-two. After graduating from Dalhousie University, and passing several years as a teacher of mathematics and physics, he went in 1873 to Germany, where he underwent a thorough course of physical training at Leipzig. Here he received, in 1876, the doctor's degree, presenting an able dissertation on the absorption of gases by saline solutions, based on a most exhaustive and extensive series of experiments. The following year was passed in research in Helmholtz's laboratory at Berlin, where Dr. Mackenzie, among other results, succeeded in showing that in the relations hitherto supposed to exist between light and electricity, the optical phenomena observed were not due to electric tension itself, but probably in a secondary manner to the heat evolved. In 1877 he accepted a call to the Chair of Physics at Dalhousie University, Nova Scotia. At the commencement of a scientific career from which much was expected by his numerous friends, he was suddenly taken away by an insidious complaint induced a year since by the inhalation of the nitrous fumes from a Bunsen battery.

M. Gyldén has been elected a Corresponding Member in the Astronomical Section of the Paris Academy in place of the late Father Secchi.

We notice the appearance in May of the German *Jahresberichte über die Fortschritte der Chemie* for 1877. The present volume forms the thirtieth of the series founded by Liebig and Kopp, and is at present under the editorial supervision of Prof. Fittica of Marburg, assisted by a corps of eleven German and Austrian chemists. It is by far the most important and the most extensive of all annual reviews, and affords to even a superficial observer an interesting glimpse into the variety and extent of the chemical discovery of our day. Of its 1,400 pages, 196 are devoted to theoretical and physical chemistry, 120 to inorganic chemistry, 714 to organic chemistry, 66 to analytical chemistry, 152 to technical chemistry, 104 to mineralogy, and 46 to chemical geology. Of the space devoted to organic chemistry—more than one-half of the work—364 pages are occupied with the chemistry of the aromatic series, 48 with animal chemistry, 47 with vegetable chemistry, &c. The index of anthors contains over 1,750 names, and in comparison with the indices for 1867 (850 authors) and 1857 (720 authors) shows the rapid increase of late years in the number of those devoted to chemical research. Nine volumes of the *Jahresbericht* are now out of print, and complete sets are quoted at 800 marks. Individual volumes bring as high as 100 marks. German booksellers state that this rarity is occasioned in a notable degree by recent extensive purchases for public and private libraries in the United States.

During the past week Etna has been in active and increasing eruption. A very considerable number of new craters have opened, and that on both flanks of the mountain. The lava has reached many miles from the mountain, almost to the River Alcantara, laying waste the surrounding country. The village of Mojo has been destroyed, and others are threatened.

A volcanic eruption which has broken out in a mountain on the banks of Lake Balaton in Hungary, seems to have begun almost simultaneously with that of Etna, referred to in next note.

THE following are the most recent reports of earthquakes from various quarters:—From April 25 until May 2 repeated violent shocks were felt in the Senio valley in the Romagna. Several buildings were destroyed completely and many others damaged. The village of Palazzuolo suffered most, and the inhabitants left the dwellings and camped out in the fields.—Another series of shocks occurred at Shabka, in the Soroki district, Bessarabia; they were preceded by a subterranean noise similar to the report of a cannon, followed by a long rumbling noise. Twenty-four houses fell in; fissures appeared in the soil, from which water flowed out. Fifty-four trees were uprooted.—A third and fourth phenomenon of this nature were observed at Serajewo (Bosnia) on May 14 in the morning, and at Maramaros-Szigeth (Hungary) on May 18 at midnight. Altogether the volcanic phenomena in the Austrian Empire have been remarkable recently, and the signs of eruption shown by the Csobancz, one of the mountain cones on the shores of Lake Balaton, which has been extinct for centuries are no less so.—The last report which has reached us comes from Batavia, where, on April 4, a violent earthquake was observed. At Tjandjoer, some fifty miles from Batavia, a number of stone houses fell, burying many of the inhabitants beneath their ruins.—A Samarang paper states that the volcanoes in Eastern and Western Java are simultaneously in eruption. From the Smeru volcano a broad fiery stream of lava is making its way through a ravine to the sea-shore on the south, while at the other end of Java the Gedeh mountain is casting out an immense quantity of ashes, which spread themselves for miles round the neighbourhood.

AN exceptionally large meteor was observed at Herford (Westphalia) on April 25 at 8.30 P.M. The nucleus was nearly of the apparent size of the moon's disk, and its light was so brilliant that while the phenomenon lasted (*i.e.*, three seconds) no fixed stars could be seen.

THE Italian State Secretary for Public Buildings has sanctioned the plans submitted to him for the construction of an observatory on the summit of Mount Etna.

THE Anthropological Exhibition at Moscow seems to be one of great interest. It is contained in a vast building lent by the Minister of War, and used in winter for drilling soldiers, and the exhibition has been rendered as picturesque as it is scientific. A garden which has been arranged most artistically for the purpose presents, among other features, a very remarkable "palæontological valley." This is planted with lycopods, gigantic ferns, and other fossil plants; this forest is inhabited by models representing megatheriums, mammoths, ichthyosaurs, &c. On miniature mountains, the age of which is indicated by artificial geological sections, are shown *fac-similes* of Russian, French, Danish, and other tumuli. Besides this, an ethnological garden is peopled with models representing the principal human types, especially those of Russia. There is, besides, a remarkable anatomical and craniological exhibition. Altogether this is one of the most remarkable anthropological exhibitions ever brought together, and has been an immense success.

THE question of the definite location of the observatory for which a legacy of 700,000 dollars was provided by the late James Lick, has resolved itself into a selection of one of the three peaks of Mount Hamilton—Observatory Peak, 4,302 feet high; East Peak, 4,448 feet; and Middle Peak, 4,318 feet. At the suggestion, it is said, of Prof. Simon Newcomb, of the U.S. Naval Observatory, to whom the question was submitted, the trustees have referred the subject of a selection to Mr. S. W. Burnham, an amateur astronomer of some distinction. So soon as this decision is announced, the work of erection will be at once proceeded with.

A FEW weeks ago the fossil head of a *Rhinocerus tichorhinus* was found in Siberia, and is said to be in a very good state of preservation. The valuable object was presented to the Museum of Moscow University by the Siberian branch of the Russian Geographical Society, and will find a place in the Anthropological Exhibition at Moscow.

A NEW sensation is in store for visitors to Niagara; whether desirable or otherwise will depend on the tastes of the visitors. The "Niagara Falls Prospect Park Company" have ordered one of the largest-sized Brush machines and sixteen lamps, wherewith, by means of parabolic reflectors and otherwise, to throw light upon the descending water and upon the mist, "thus producing electric rainbows to order in the darkest night." It is also expected that a light can be placed behind the American fall, so as to throw rays out through the water.

THE death is announced of Karl Koch, formerly Professor of Botany in Berlin University.

WE hear that the Abbé Moigno, the editor of *Les Mondes*, who has just published a work in three volumes called "Les Splendeurs de la Foi," has disposed of his journal, and will proceed to Rome in order to lay before his Holiness the *comble* of his science. He may eventually be rewarded by being made a cardinal.

A VENERABLE relic of past engineering skill has been presented by the Earl of Lonsdale to the Patent Office Museum, South Kensington, where it may be seen by the public. This is a specimen of Heslop's Winding and Pumping Engine, a patent for which, numbered 1,760, was taken out in the year 1790. Heslop's engine, one of the immediate predecessors of James Watts's invention, was considered in the days of our great grandfathers to be an almost perfect machine, being superior to the atmospheric engine of Newcomen, even as improved by Smeaton. The present engine has been at work in the neighbourhood of Whitehaven for seventy-three years, having been erected at Kell's Pit for raising coal about 1795, afterwards removed to Castlerigg Pit, and thence to Wreath Pit in 1837. At the latter place it not only lifted coal out of the mine but worked a pump till last summer, when it was brought to London. The engine now at South Kensington is the last survivor of its race.

A TELEGRAM from New York, June 1, states that the States of Kansas and Nebraska have been visited by a tornado, by which about forty persons were killed and over one hundred wounded, while fifty buildings were destroyed, and the crops and other property greatly damaged.

MR. W. H. COFFIN writes us with reference to our note last week on the *conversazione* of the Institution of Civil Engineers. He states that the electric lamp for surgical use exhibited by him is an improved modification of M. Trouvé's "Polyscope Electrique," devised and constructed by Messrs. Coxeter and Son, the surgical instrument makers.

THE Municipal Council of Paris has resolved to adopt the cremation system on sanitary grounds.

AMONG various applications proposed by M. Planté for his secondary couples is that of electrical drilling. It is known that those high-tension currents (which he produces), when made to act on glass in presence of a saline solution, act like a graver or diamond, tracing grooves and making considerable hollows. Rock crystal may be thus attacked, spite of its hardness, and if it is not regularly engraved, it at least breaks into small fragments, and is ultimately disaggregated. Now, in America, black diamonds are used to attack hard rocks and effect the borings for mines. Might not these (M. Planté asks) be advantageously replaced by action of

the electric current in the way indicated? (The diamonds are very expensive and are gradually lost by being detached from the pieces to which they are fixed.) Platina electrodes would not be necessary, for it is not here the metal of the electrode that is altered, but the silicious matter, in presence of the saline solution. Metallic points or rods distributed suitably at the end of the drill-stem, insulated in part of their length and animated by rotatory motion, would bring the electric current to the surface of the rock to be pulverised. The progress recently realised in the production of electricity by mechanical means might facilitate this application.

IF perpetual motion be defined as that of a body which, after having received an impulse, continues to move indefinitely in virtue of its inertia alone, it is, M. Plateau considers, realisable. He introduces a foreign force of constant nature to destroy resistance, instead of (as in the case of a pendulum) restoring motion which resistance has withdrawn. Thus, conceive a horizontal disk movable round a vertical axis fixed to the centre of its under surface. A small hemispherical cavity is made on the upper face. A motor force of rapid rotation is got from a reservoir below the lowest water of a river, giving a uniform intense flow by a lower orifice. Before letting the water act on the disk, a top, previously set in very quick rotation, is deposited with its point in the middle of the hemispherical cavity; then the top is covered with a glass bell jar, which is fixed with its axis coinciding with that of the apparatus. The disk with the bell jar is then set rotating by means of the water in the same direction as the top. After a certain time (it may be supposed) the movements of disk, top, and inclosed air will be equalised; then the top will no longer experience resistance at its point, for the support turns as quickly as it and in the same direction; nor will it, from surrounding air, for this also has the same angular velocity. Thus we should have the curious spectacle of a top remaining indefinitely in equilibrium on its point, presenting a case of perpetual motion in the sense defined. Of course the water would have to be let off after action on the apparatus, also the surplus water of the reservoir.

WE have received from Messrs. Dent and Co. an interesting summary of the principal works executed by that house since its foundation in 1814. The last noted is the commencement in 1879 of the great galvanic chronographic apparatus of the Imperial Observatory of Japan.

TWO other volumes of the "Natural History Rambles" series have been sent us by the S.P.C.K.—"Mountain and Moor," by Dr. J. E. Taylor; and "Lakes and Rivers," by Mr. Groom Napier.

THE Asiatic Society of Japan are showing considerable activity in the issue of their publications, for another number of their *Transactions* has lately come to hand. This opens with some curious notes on the analysis of bamboo-shoots, which are much used as an article of food in Japan. Dr. Dwars arrives at the conclusion that the shoots examined at that period of their development must be considered a nourishing vegetable, and that they may even rival the cauliflower and asparagus. Mr. Satow supplies the first of a series of papers on ancient Japanese rituals, as well as some instructive notes on the vicissitudes of the Church at Yamaguchi from A.D. 1550 to 1586.

A NOTABLE change has taken place in the Jardin des Plantes of Paris, and should be noticed by foreigners. All the galleries and houses are open every day from one to four without any ticket of admittance being required from visitors. The plant-houses only are closed on Sunday.

A MUNICIPAL SCHOOL has been recently established in Paris for apprenticeship in the work of wood and iron.

A PART of the buildings of the Universal Exhibition has been purchased by the French War Office for the use of the aëronautical school at Meudon. It will be utilised for building and inflating balloons.

THE large Giffard Captive Balloon is ready for inflation, and the gas will be passed into it as soon as the state of the weather will permit the operation to begin.

THE additions to the Zoological Society's Gardens during the past week include a White-thighed Colobus (*Colobus bicolor*) from West Africa, presented by Dr. H. Hart; two Silky Marmosets (*Midas rosalia*) from South-East Brazil, presented by Mrs. Hector; a Capybara (*Hydrochœrus capybara*) from South America, presented by Mr. H. B. Whitmarsh; a Puff Adder (*Vipera arietans*) from West Africa, presented by Surgeon F. Speer; a Brown Hyæna (*Hyæna brunnea*) from South Africa, an Argus Pheasant (*Argus giganteus*) from Malacca, purchased; a Michie's Tufted Deer (*Elaphodus cephalophus*) from China, deposited; an Axis Deer (*Cervus axis*), born in the Gardens.

PREHISTORIC INVESTIGATIONS IN AUSTRIA[1]

I. *Lower Austria.*—At Mount Calvary, near Pellichsdorf, on the Marchfeld, a plain east of Vienna, explorations conducted by F. Heger, from June 26th, to July 28th, 1878. A great number of urns, pateræ, &c., of peculiar forms, not known from any other locality. Although broken by pressure, thirteen were more or less susceptible of reconstruction. Most of them were found in a space inclosed with strong beams of wood. A broken bronze armlet was also met with.

II. *Carniola.*—Explorations conducted by von Hochstetter and Ch. Deschmann, Superintendent of the Provincial Museum of Laibach.

1. Terszisce, near Zirknitz, July 16th, 1878, Prehistoric Fortified Station, and burial-ground, with human bones, more or less burnt, and many objects of bronze and iron, like those of the Celtic burial-ground of Hallstadt in Upper Austria.

2. Grad, near St. Michael, not far from Adelsberg, July 23rd, 1878. Separate skeletons, bronze objects, and Pre-Roman coins.

3. Slemschek, near Waatsch and Littai. Prehistoric Station of the "Hallstadt Period," with extensive burial-place. The graves are flat: some contain skeletons; others burnt remains. The latter are covered with heavy stone slabs, and contain large urns, of various forms, which have burnt bones within or underneath. Many objects, both ordinary and ornamental, of bronze, iron, amber, glass, bone, &c., were found, including a bronze helmet in excellent preservation. From July to October, 1878, about 200 graves were examined, mostly at the cost of the Provincial Museum of Carniola.

4. Dolle, near Gora and Waatsch. Separate graves, of the same character as those at Slemschek.

5. Vier, between Sittich and St. Veit, Lower Carniola. Above the village is a perfect ring-shaped earth-work; below it, on both sides of the high road a number of tumuli. Nearer St. Veit are flat graves, covered with slabs. This was probably the place of the *Acervone* of the Pentigerian Tables, or the Roman *ad Acervos*, which name, according to Prof. Müllner, is derived from these Pre-Roman tumuli.

6. Moratzch, near Heiligenkreuz. Flat graves and tumuli, August 1st, two skeletons were dug out, a male and a female, with earthen vases, iron knives, and a bone comb. These burials are probably later than those of Nos. 1-5.

7. Mariathal, south-east of Littai. Ancient castle surrounded with a rampart; also flat graves and tumuli containing skeletons August 2nd and 3rd, a male skeleton without arms, and with violently fractured skull was exhumed, together with many objects, including an elegantly ornamented urn, similar to those found at Slemschek.

8. Ober-Strascha, on the left bank of the river Gurk, above Rudolfsworth. Old ring-rampart and a few scattered tumuli.

[1] "Prehistorical Investigations in Lower Austria, Carniola, and Bohemia." By F. von Hochstetter, President of the Prehistorical Commission of the Imperial Academy, Vienna. (Imperial Academy of Sciences, Vienna, Meeting, January 16, 1879.)

9. Gradische, near Tepliz, Lower Carniola. Ancient castle with rampart.

10. Gsindeldorf, near Weisskirchen. Numerous tumuli, and traces of ancient dwelling-places; and some few bronze objects.

11. Landstrass, on the River Gurk. Many tumuli.

Besides the above localities of prehistoric dwelling and burial places, six others are known, but not yet explored.

12. Kreuzberg Cave, near Laas. This is very extensive, difficult to get at, and abounding with bones. In four days more than 2,000 bones of *Ursus spelæus*, besides more or less perfect skulls of the Bear, were taken out, belonging to at least from 40 to 50 individuals and possibly to a hundred and more. Most of the bones were scattered, but some remained together, so that a perfect skeleton was obtained for the Imperial Mineralogical Museum. Besides bones and teeth of the cave-bear, remains of *Gulo spelæus* and of a Marten (near *Mustela foina*), also cervical vertebræ of *Lupus*, and coprolites of *Hyæna* were found in this cave.

13. Jellenza Cave, near Tepliz, Lower Carniola. Excavations, August 5th, 1878, showed that this cave had been in-inhabited by Man.

III. *Bohemia.*—Of late years many antiquities have been met with about Hradischte, near Beraun, probably dating from the Marcomans and their predecessors the Boyans, who lived here apparently for centuries. Their burial-places, the tumuli near Lisek, and the old cemetery near Althütten, with its urns, have to be further explored. T. R. J.

SCIENTIFIC SERIALS

American Journal of Science and Arts, May.—Some experiments in cross-breeding plants of the same variety are here described by Prof. Beal, having been suggested by Darwin's book. The plants were Indian corn and black wax beans.—Prof. Young records observations of the spectrum of Brorsen's comet made on April 1 and 2. He is quite positive that the middle band of the spectrum now coincides sensibly (to a one-prism spectroscope) with the green band of the hydrocarbon spectrum.—Dr. Southworth demonstrates this theorem: If a hydrated salt be dissolved in a given volume of water, the volume of the solution will exceed the original volume of the water by a bulk equal to the bulk of saline water contained in the salt dissolved.—The first portion of a paper by Prof. Norton, on the force of effective molecular action, appears in this number, and the remaining papers deal mostly with geological subjects of more local interest, the Fox Hills Group of Colorado, the Hudson River age of the Taconic schists, the Wappinger Valley limestone of Dutchess County, N.Y., the Huronian series of Northern Wisconsin, the mineral locality in Fairfield County, Connecticut, &c.—Mr. Peters gives observations on the planet he discovered on March 21.

Annalen der Physik und Chemie, No. 4.—Herr Kayser here arrives at the conclusion that the velocity of propagation of sound-waves is independent of the intensity of the tone. His final method (two others, with use of Kundt's dust-figures, having been rejected) was to note the phases of vibration of a piece of mica at the top of a vertical glass tube used for resonance to a tuning-fork above it, set vibrating with different intensities by electric means. Water could be admitted laterally at the bottom of the tube, so as to obtain the maximum resonance. As the water-stopper is displaced, the same figure of vibration always returns whenever the displacement has reached half a wave-length. Herr Kayser finds the velocity of sound in free space 332·5m., calculated by Kirchhoff's formula from velocity in tubes, and making therein $\gamma = 0·0235$. (The case of explosion-waves is excluded from consideration, these being quite distinct in kind from sound-waves.)—Herr Wiedemann, in extension of a former research, takes up a number of points relating to torsion; repeated torsion in the same, or in opposite direction, permanent torsion of a wire often twisted a certain amount, influence of weighting during permanent and during temporary torsion, influence of oft-repeated weighting, rotation of molecules, action of vibrations, &c.—Herr Auerbach, considering (from the physiological, psychological, physical, and musical stand-points) what is the absolute number of vibrations required for production of a tone, thinks it is probably about *twenty*.—Herr Schmidt furnishes a new table of gas densities.—Herr Zöppritz continues his papers on hydrodynamic problems in relation to the theory of ocean currents.—Herr Sohncke replies to an objection by M. de Lapparent to his new theory of crystalline structure.—We have elsewhere referred to Herr Elster's researches on the electromotive forces which occur in free water jets.

Atti della R. Academia dei Lincei, March.—We note here the following:—On the secular variation of the magnetic needle at London since the year 1580, by Mr. Jenkins.—Researches on Cinchonine, by Prof. Fileti.—On the atmospheric disturbance of February 24 and 25 last, by S. Respighi.—On prenite and laumonite from the mines of Montecatini, by Prof. Bechi.

Reale Istituto Lombardo di Scienze e Lettere. Rendiconti. Vol. xii. fasc. vi.—We note here the following:—Influence of manures on the combustibility of tobacco, by S. Cantoni.—Considerations on the palatine bones, by Prof. Verga.—Some studies with reference to physiology and the expression of attention in man, by Dr. Riccardi.

Fasc. vii.—Rigid suspension bridges, by S. Clericetti.—On the area described by an invariable line moving in a plane according to a determinate law, by Prof. Bardelli.—On arithmetical hemiteria, by Prof. Maggi.—Some reflections on a recent note of Jamin, on the theory of dew, by Prof. Cantoni.—Reflections on the theory of dissimulated electricity, by S. Serpieri.—A steel yard densimeter, by Dr. Chistoni.

SOCIETIES AND ACADEMIES

London

Royal Society, May 8.—"On the Results of the Magnetical Observations made by the Officers of the Arctic Expedition 1875-76," by Staff-Commander E. W. Creak.

1. After leaving Portsmouth the first magnetical observations were made at Godhavn, Disko. On arrival at winter quarters, observatories were constructed where observations of the three magnetic elements and hourly observations of the differential declination magnetometers were made during the winter.

2. The diurnal variation or inequality of the declination formed one of the chief objects of interest at the winter quarters, as, although the period was remarkable for frequent magnetic disturbances, and an absence of brilliant auroras, no connection could be observed between appearances of that phenomenon and the movements of the declinometer magnet. This accords with the remarks of previous observers within the region comprehended between the meridians of 60° and 90° W., and north of the parallel of 73° N.

3. It has been established that 8 A.M. and 1 to 2 P.M. are the hours of the greatest easterly and westerly deflection of the declinometer magnet in middle latitudes. At the winter quarters, Discovery Bay, the westerly extreme was reached at 10 A.M., the easterly at 11 P.M.

4. An analysis of the disturbances of the declinometer magnet showed that the disturbing force never ceased, that it was at a minimum about the solstice, and a maximum at the equinox, and was greater during the day than the night.

5. Comparing the days of principal disturbance at Kew and at the winter quarters' observatories, it was found that for the most part the disturbances occurred on the same days. The two greatest disturbances or "magnetic storms" occurred on February 19 and March 25-26, 1876, during the same hours of Greenwich mean time as at Kew, but the magnets were often in opposite directions from the normal at the two stations.

6. An important result obtained was the evidence of but small secular change having occurred in the inclination and force since the observations of Kane and Hayes in 1854 and 1861 respectively. The declination is, however, more decidedly changing, especially about Godhavn, the needle moving towards the east as in England.

May 15.—"Note on a Recent Communication by Messrs. Liveing and Dewar," by J. Norman Lockyer, F.R.S.

In my paper of last December[1] I called attention to the importance of discussing Young's observations of the chromospheric lines in connection with the spectra of the metallic elements. In subsequent communications I have given preliminary results of this discussion so far as it has already proceeded.

Since my paper was read Messrs. Liveing and Dewar have, in a paper printed in the last number of the *Proceedings*, given a table which professes to state the number of times various lines in certain metals were seen by Young in connection with certain reversal phenomena observed by themselves.

[1] *Proceedings*, No. 191, p. 172.

The statements, however, made in this table with regard to the visibility of certain lines in the chromosphere do not appear to be in accordance with Young's published tables, and as Messrs. Liveing and Dewar have in a still later paper drawn theoretical conclusions from these statements, I think it desirable to call attention to the fact, in order to prevent any confusion which might otherwise arise.

It will be sufficient to refer to two cases.

I. Messrs. Liveing and Dewar state that two lines of aluminium, the wave-lengths of which they give as 6245 and 6237, have each been seen by Young eight times.

According to Thalén's measurements, which are the best that we possess, there are no lines of aluminium in these positions. He gives, however, lines at 6244·0 and 6234·0.

Young, moreover, states that he saw reversed a strong line (clearly shown in Ångström's map to be an iron line) at 6245·4, and a line which he does not ascribe to any element at 6237·3, which is more than three divisions of the scale from the position of the aluminium line.

II. In the case of potassium, Messrs. Liveing and Dewar give two lines at wave-lengths 4044 and 4042 as having been seen by Young three times. I know of no potassium lines at the places given; Young, moreover, has recorded the reversal of no potassium line in this region. What Young distinctly states he saw, was the reversal of the iron line at 4045·0, which is one of the most marked iron lines in the spectrum of the sun. To this reversal I referred in my paper of December 12.[1]

It is perfectly true that there are two potassium lines in this region: they were not mapped by Thalén, and they were only seen as a single line by Lecoq de Boisbaudran[2] and the wave-length, given as 4045, as his dispersion was limited, did not enable us to determine its true position with reference to the Fraunhofer lines.

Last year, however, I not only stated the double nature of this line on photographic evidence,[3] and pointed out that both components were absent from the spectre normal, but I gave their wave-lengths as 4042·75 and 4046·28 (positions which will only find the last place of decimals altered, even if it be altered, in the revision of the map now being proceeded with), and on the strength of them announced the existence of potassium in the sun. Messrs. Liveing and Dewar do not state whence their wave-lengths were derived, neither do they refer to my communication.

It would appear therefore not only that the reference to Young's work in many cases is founded upon some misunderstanding, but that a higher degree of accuracy than that employed by Messrs. Liveing and Dewar is necessary to determine such coincidences.

I may state generally that my eleven years' work on this special branch has led me to the conclusion that all statements of coincidences between metallic and solar lines with a lower degree of accuracy than that employed by Thalén and Young are to be avoided when possible, as they may be worse than useless, they may mislead. Indeed, though the map on which I am working is on twelve times the scale of Ångström's, it would be better if it were larger; and when I say this I must add my tribute of admiration of the accuracy of the work of those who have preceded me, notably Ångström, Thalén, Cornu, and Young, with whose work I am more familiar, as it is expressed in wave-lengths.

May 29.—"Note on the Spectrum of Sodium," by J. Norman Lockyer, F.R.S.

I have lately been engaged in studying the spectrum of sodium under new experimental conditions. In anticipation of a detailed communication I take leave to state that the vapour given off from the metal after slow distillation in a vacuum for some time shows the red and green lines without any trace whatever of the yellow one. Hydrogen is given off in large quantities, and at times the C line and the red "structure" are seen alone. After this treatment the metal, even when red-hot, volatilises with great difficulty.

Linnean Society, May 1.—Lieut.-Col. Grant, C.B., vice-president, in the chair.—Mr. Edw. S. Morris exhibited a quantity of the berries, whole and ground, of the *Coffea liberica*, grown by him near Monrovia.—A living example of the rare and curious *Welwitschia mirabilis*, reared at Kew, was shown and commented on by Mr. W. T. Thiselton Dyer.—The chairman also called attention to a series of the teaching diagrams illustrating the "Anatomisch-physiologischer Atlas der Botanik," now being issued by Dr. Arnold and Carolina Dodel-Port, of Zurich.—A paper on nutrition in its relations to the fertilisation of flowers, by Mr. Thos. Meehan (Philadelphia, U.S.), was read. His observations chiefly refer to *Wistaria sinensis*, *W. frutescens*, *Catalpa syringæfolia*, and *Limina perenne*, from which he deduces that the struggle for power between the growth or vegetative and the reproductive forces decides fertility. He further suggests that the perfection of the polleniferous organs, and consequent potency of pollen, is dependent on phases of nutrition involved in this struggle. Thus in the above-mentioned plants it is seen that potency in pollen—the main element in the reproductive force—operates only when there has been some check given to the force of vegetative growth.—The Rev. G. Henslow read some remarks on Mr. Meehan's contribution, these in the main supporting his views. He states, with regard to the different facts and interpretation of experiments, that results however accurate and true for one country may be very different for another, as has been shown to be the case with *Escholtzia*. We cannot, therefore, be too cautious in presuming that because a phenomenon may invariably occur in our experience it must necessarily do so everywhere and at all times. He recognises five degrees in the effects of the reproductive force—1. Entire abeyance when no flowers are produced. 2. Flowers abundant, but pollen remains a mass of tissue, as in *Ranunculus ficaria*. 3. Flowers produced with good pollen, but no seed set as in *Escholtzia*. 4. Fruit produced only at definite places, as extremity of raceme, or at definite periods, as late in summer. 5. Flowers and fruit occur in abundance as in "tree" *Wistaria*, or freely growing branches of ivy.—A paper on the structure of the Pouched Rats, of the genus *Heteromys*, by Dr. J. Murie, was read in abstract. The anatomical structure and other peculiarities have been worked out and a comparison with other forms given, along with remarks on the sub-family Heteromyinæ generally.—The Secretary read a note by Dr. M. Masters, on the occurrence of a Restiaceous plant in Cochin China, an interesting fact in the geographical distribution of the group.—Messrs. T. E. Brown (of Adelaide), Richd. Rimmer, and P. O. Shanessy (of Queensland), were elected Fellows of the Society, and two Foreign Members were chosen to fill vacancies.

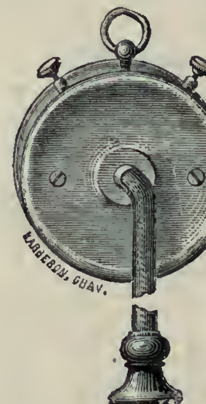
Geological Society, May 14.—Prof. P. M. Duncan, F.R.S., vice-president, in the chair.—The following communications were read:—Further observations on the pre-Cambrian rocks of Caernarvon, by Prof. T. M'Kenny Hughes, F.G.S. The author divides these into (1) the volcanic series, (2) the felsitic series, (3) the granitoid series. He traces the former of these, consisting of coarser and finer varieties, from Caernarvon to near Port Dinorwig. Beyond these come the felsite series, which is overlapped by grits and conglomerates as far as the Bangor Road, north-east of Bri hdir. Above the latter comes the "volcanic series," well developed in the neighbourhood of Bangor. The author is of opinion that the Cambrian conglomerate, with associated grits, may be traced in the edge of the older massif from Twt Hill, Caernarvon, to Garth Point, Bangor, and that the beds in each of these places and near Brithdir, recently described as separate, are identical; also that the bed with purple fragments near Tairffynnon and the Bangor Poorhouse are only Cambrian conglomerate faulted down. Further, he considers that the strata of the above three series are fairly parallel throughout, and that they only form three subdivisions of one great series.—Notes on the structure of the palæozoic districts of West Somerset, by A. Champernowne, F.G.S., and W. A. E. Ussher, F.G.S. The authors confirmed the general accuracy of Mr. Etheridge's views as to the structure of North Devon and West Somerset, but differed from him in ascribing the limestone of Cannington Park to the carboniferous, both on account of lithological character, the fossils in Taunton Museum, said to be obtained from it, and the latitude of its position with reference to the carboniferous limestone of the Mendip, South Wales, and the steep and flat Holmes. They described four traverses made by them in West Somerset. 1. From Dulverton to Dunster, in which, proceeding northwards, the following beds were encountered:—Culm-measures faulted against Pilton Beds (upper Devonian), Pilton Beds faulted against Pickwell-Down sandstone (base of upper Devonian), Pickwell-Down sandstones becoming slaty in passing into Morte slates (middle Devonian) and troughed in them by faulted synclines, Morte slates passing into Ilfracombe slates (overlying Hangman grits) near Cutcombe, Hangman grits, evidently

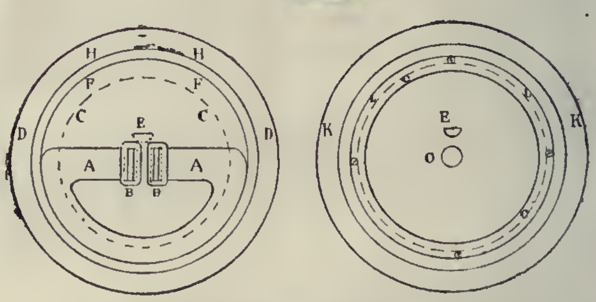
[1] *Proceedings*, 191, p. 172.
[2] "Spectres Lumineux," texte, p. 48.
[3] *Proceedings*, No. 186, p. 280.

faulted against Foreland grits, as no representative of the Lynton beds is present between Oaktrow and Timberscombe. In traverse 2 the fault between the Hangman and Foreland grits is proved by the presence of the Lynton beds in the valley west of Luccot Hill and their conformable infraposition to the Hangman series, and abrupt termination by fault against the Foreland grits of Porlock and Oare Hills. At Oare a patch of schist of the Lynton zone was noticed resting on the Foreland grits on the north side of the fault. The 3rd traverse in the Tone Valley gave the following succession of beds:—Culm-measures on Pilton beds; Pilton beds with grits, much flexured, on Olive slates with *Lingula* and grits with *Cucullæa*, conformably overlying Pickwell-Down grits, which make a conformable junction (following the feature) with the underlying quartziferous slates of the Morte series (middle Devonian); the latter were observed between Huish Champflower and Clatworthy; but, as the middle Devonian slates appear to extend considerably northward in the Brendons, they were not traversed beyond Clatworthy. The 4th traverse from West Quantockshead to Cannington Park proved the composition of the Quantocks along that line to be grits, in places associated with schistose shales, apparently belonging to the Hangman series (middle Devonian); whilst the palæozoic inliers, in the triassic area of Bridgewater, are unlike the Quantock rocks in character. The limestones of Asholt and Hollwell, associated with slates of the Ilfracombe series, are very similar to varieties of the South Devon limestone, and are quite unlike the limestone of Cannington Park.—The Whin Sill of Teesdale as an assimilator of the surrounding beds, by C. T. Clough, F.G.S. Owing to the general absence of mechanical disturbance, the author is of opinion that "the Whin consists in part of altered sedimentary beds, that it partly represents beds which were once in the position it now occupies, that it did not make room for itself simply by thrusting aside these beds, but also by incorporating them into itself." He proceeds to describe sections at Caldron Snout, Cronkley Fell, Noon Hill, &c., which seem to him inexplicable on any other theory. The author discusses objections on chemical grounds, holding that the general uniformity in chemical composition of the Whin may be explained by supposing the absorbed beds to have permeated a large mass of the Whin, as an alloy does melted metal. He thinks the explanation may be extended to other intrusive masses.—On the silurian rocks of the valley of the Clwyd, by Prof. T. M'Kenny Hughes, F.G.S. The author gives a preliminary sketch of the silurian rocks of the southern and western part of the Clwyd Valley. He describes first some beds below the horizon of the Denbigh grits at Ffriddfawr which agree very well in their characters with the base of the Coniston grit, and others near agreeing with the passage-beds between these grits and flags. He next describes sandstones in the Clywedog Valley, the equivalents of the lower grits; and lastly, at Bod Renail, flags, &c., the Pale States, which contain graptolites, and are thus to be identified with the graptolitic mudstones of the Lake-district. Thus he is of opinion there is a basement-series here for the Silurian, corresponding in all its details with that in the Lake-district.

Zoological Society, May 20.—Prof. W. H. Flower, F.R.S., president, in the chair.—Mr. Sclater called the attention of the meeting to several animals and other objects of interest observed by him during a recent visit to some of the zoological gardens on the Continent.—Prof. Owen, C.B., read a paper in which he gave the description of a portion of the mandible of a large extinct kangaroo, proposed to be called *Palorchestes crassus*, from the ancient fluviatile drift of Queensland.—A communication was read from Mr. M. Jacoby, containing descriptions of new species of coleoptera of the family *Halticidæ*.—Mr. Sclater read a paper (the fourth of the series) on birds collected by the Rev. George Brown, C.M.Z.S., on Duke of York Island, and on the neighbouring parts of New Britain and New Ireland. The present collection contained fifty-nine specimens belonging to forty-two species, of which several were believed to be new to science.—A communication was read from Prof. Garrod, F.R.S., containing a series of notes on the anatomy of the Gelada baboon (*Gelada rueppelli*), based on the examination of a specimen that had died in the Society's Gardens. Prof. Garrod came to the conclusion that *Gelada* must be considered as a distinct generic form, more nearly allied to *Cercopithecus* than to *Cynocephalus*.—Lieut.-Col. Godwin-Austen read some notes on and gave a description of the female of *Ceriornis blythi*, Jerdon.

Physical Society, May 10.—Prof. W. G. Adams in the chair.—New Member, Mr. J. Kestrell Evans.—Mr. Wollaston explained the construction of Gower's improved form of Bell's speaking-telephone. The older form, made of wood or ebonite, is open to the objections that it has a very weak voice, soon gets out of adjustment from changes of temperature, and requires a twisted hand-wire which is liable to break. Gower's form has a comparatively loud utterance, is constant, and does not require to be held in the hand, but may be laid on a table or hung on a wall, a speaking-tube leading from it to the operator's ear or mouth. The "call" for attracting attention is also within the Gower telephone itself, whereas in the hand telephone it is an auxiliary apparatus. Every organ of the old telephone has been modified to form the Gower. The magnet A A in the figure in the Gower is of a horse-shoe form, very powerful, the two poles being brought very close together, and each pole is mounted with a small coil of fine wire, B B; the diaphragm C C is much thicker and longer than the Bell diaphragm, the case, D D, is of brass, to expand equably, and a speaking-tube is fitted to the front of the diaphragm. F F is the interior and K K the exterior circumference of the box. The call, E,





consists of a musical reed attached to the diaphragm so as to be opposite a small slit in the latter. To sound the call it is only necessary to send a sharp puff of wind up the speaking-tube, and the reed gives out a note which is heard throughout a room at the distant end. Speaking and cornet music was transmitted by the instrument exhibited, between the third storey over the hall and the meeting. It was very distinct and audible several feet from the receiver. Speaking done some thirty feet from the transmitter was also sent. Conversation was likewise carried on while considerable noise was being made in the room. Prof. Macleod remarked that the timbre of this telephone was very good. —Prof. Barrett then gave an account of some attempts which he had made to overcome the induction clamour on telephones caused by the ordinary telegraph currents on neighbouring wires. He had tried recently the Bell telephone on a line from Dublin to Armagh, ninety-five miles long, but the induction noises completely stifled the speaking, whereas the Edison transmitter gave good results. The clamour could be got rid of either by neutralising the induction currents, or by eliminating the noises from the speech. He had taken the second line of experiment. Since the vocal currents differ from the induction ones in potential and period, he attempted to make the latter discharge across from the line to earth by fine needle points, and from a heated spiral of wire, in a vacuum, leaving the vocal currents to

pass on to the receiver, but without success. Also since the vocal currents are alternately positive and negative, whereas the induction ones are of one sign, he tried to avail himself of the difference in discharging power of positive and negative currents, but without success. He then tried to take advantage of the difference of period or duration of the currents, the induction currents being longer. He therefore tried to break up the induction-currents by interposing a rapidly revolving current interrupter, and to make the sections of the musical note obtained *interfere* with each other by means of an acoustic interference-tube, but practically failed in this also. He mentioned these facts for the benefit of others who may be going over the same ground. Mr. Wollaston pointed out that a perfect cure for induction on underground wires consisted in twisting the going and returning wire of the telephone circuit round each other.—Mr. Wilson then read a paper on the divisibility of the electric light by incandescence. By Joule's law the amount of heat developed in a circuit of resistance, R, by the passage of a current $C = C^2 R$; where R is the resistance of generator and connections, r, added to the resistance of the light emitter or incandescent wire, P. Therefore since by Ohm's law $C = \frac{E}{R}$ we have—

$$C^2 = \frac{E^2}{(r + P)^2}, \text{ and } C^2 P = \frac{E^2 P}{(r + P)^2}.$$

From this equation the value of P may also be determined. $C^2 P$ is the amount of heat developed in the incandescent wire. He infers that the smaller the mass of the wire the higher the temperature generated in it, therefore the mass of the wire should be diminished until the fusing point of the metal is almost attained. The question of divisibility resolves itself into our being able to divide a single incandescent source into a number of smaller ones giving the same total illumination. The author concludes that this can be done by arranging the subdivided sources in "multiple arc" or parallel circuits, provided the total mass, length, and sectional area of the united sources be the same as in the original single source. The objection that increased radiation from the various sources would diminish the first total of light and heat can be met by making the smaller wires still smaller than is theoretically required so as to generate more heat. The author regards the "voltaic arc" as probably falling under the same law, the mass, however, being smaller in this case.—Dr. Coffin then exhibited a Trouvé polyscope, which consists of a small, hand, incandescent platinum wire electric light, designed for illuminating the more inaccessible cavities of the body in surgical examinations. The current is supplied by a Planté secondary battery, and the light is half inclosed in a small silver reflector fitted with a convenient handle. The apparatus is portable. Dr. Coffin found that it was open to several objections which he has remedied. Firstly, the heat generated made the lamp so hot that it could not be held to the body for more than a very short time. He overcame this by making the reflector of double silver plates, and circulating water between by means of india-rubber pipes and a bulb which can be worked by the patient himself, thus serving to distract his attention from the operation. Secondly, the secondary battery exhausts itself in twenty minutes, and the light therefore goes out, while from twelve to twenty-four hours are required to recharge it. Dr. Coffin has superseded it by a Leclanche battery of eight elements, made by Messrs. Coxetter and Sons, in which the carbon pole is replaced by a copper plate faced with platinum, and no porous diaphragm is employed. This gives a constant light for hours.

Anthropological Institute, May 13.—Prof. W. H. Flower, LL.D., F.R.S., vice-president, in the chair.—Mr. Hyde Clarke read a paper on the ethnology, mythology, and philology of races of early culture: Babylonians, Etruscans, Egyptians, Japanese, &c. Pursuing his former investigations, he now produced the comparative philology of Akkad, Coptic, Etruscan, Lydian, Phrygian, Thracian, Carian, &c., copiously illustrated. He showed the relationships of these among each other and with the Ugro-Altaic languages, Georgian, the Himalayan, Naga, Kolarian, and other Indian languages; Basque, the Pomo, Hidatsa, and other American languages. All these he further showed to be related to the numerous languages now spoken in the more advanced highlands of Central and Western Africa, as Mandingo, Bornu, Pulo, Timbuktu, Houssa, Ashantee, &c. By reference to these larger stocks he conciliated the divergences which appeared on the intercomparison of other languages. Thus he illustrated many disputed points in the Akkad grammar of M. Lenormant, and the alleged relations with the Finnic. In treating the murology of the subject Mr. Clarke referred to the marked differences between the Koord, Persian, Armenian, and Eastern Aryans, and the Germanic and other Western Aryans. His conclusion was that the so-called Eastern Aryans are descendants of the pro-existing Turanians, having merely acquired an Aryan language, and are to be assimilated to the Georgian and other white Turanians, to the Assyrians, and the Semites. To them he assigned the Etruscans and Lydians. If the Aryans were to be regarded as descended from High Asia, then the white Turanians may have descended from High Africa, and they were the authors of the early culture. When their power fell, although in Europe and Western Asia they were replaced by the Aryan migrations, yet in other regions they were extirpated by the black and brown (or red) natives. Abyssinia, in conformity with its own legends, was to be regarded as one of the last centres of this ancient empire, and the Himyarite as one of the last invasions under Semitic leaders. To the earlier epochs he assigned the American migrations and the mound-builders, when he considered the Pomo as the possible language. Tracing a like conformity in a primitive mythology as in philology, the author marked out a Turanian epoch of Greece and of Rome, and explained the relation between Etruscan and Norse mythology by the existence of a Turanian epoch of culture among the Germanic nations.—Mr. A. L. Lewis communicated a paper entitled "Notes on some Irish Antiquities." He observed that the country round Dublin, while considered by Irish antiquaries to be comparatively destitute of rude stone monuments, nevertheless contained as many as some of those districts in England where they were most plentiful. In the island of Howth, to the north of Dublin Bay, are the remains of a dolmen called Finns Quoit, the cap-stone of which measured no less than 15 feet long by 6 feet in thickness. South of Dublin, in the ground of Mount Venus, seven or eight miles from the city, is a stone 20 feet long by 3 feet thick, leaning against one 8 feet high. At Killiney Station, on the road to Bray, are remains known as the Druids Altar and Druids Chair. The finest dolmen is in Carrick mines where five upright stones support a capstone 17 feet long by 14½ inside, and nearly 5 feet thick, forming a chamber 10 feet square. In construction these remains resembled those known as the Trevethas Stone in Cornwall. Of tumuli in Ireland the largest sepulchre is probably that known in the New Grange tumulus situated between Navan and Drogheda. Its peculiarities were noticed by the author and contrasted with the remains at Gavr Inis, in Brittany, and with the cuneiform chambers at Wayland Smith, at Wellon, near Bath. Remains that have been observed in the burial-ground of the Abbey Church of Slane, near Navan, were next described, and the paper concluded with some interesting observations on the well-known round towers of Ireland, and with novel suggestions as to their origin and purpose.

Royal Microscopical Society, May 14.—Dr. Beale, F.R.S., president, in the chair.—This was the first meeting in the Society's new room.—Papers were read by Mr. A. W. Waters, F.G.S., on the occurrence of recent Heteropora; by Mr. J. Davis, on a new species of Cothurnia; and by Mr. Wenham, on homogeneous immersion objectives.—The exhibits included photographs of blood-corpuscles, by Dr. Treadwell; Rutley's petrological microscope, by Mr. T. W. Watson; and various microtomes, by Mr. Crisp, &c.—Five new Fellows were elected, and eight nominations read for the next meeting.—The second scientific evening of the session, held on May 21, was very numerously attended, many objects of novelty and interest being exhibited, together with apparatus, amongst which were oil-immersion objectives, by Zeiss and Powell and Lealand.

Photographic Society, May 13.—J. Glaisher, F.R.S., in the chair.—Mr. C. Bennett read a paper in reply to the discussion on a previous paper read by him, on gelatine emulsions. He stated that he still held the opinion that when an emulsion was lightly salted with silver bromide, the particles were fine, and remained so during long emulsification—as also the converse with heavily salted specimens. With respect to the light admitted for working his extremely sensitive emulsion, he found that four square feet of four thicknesses of deep ruby glass were preferable to one square foot of one thickness.—Mr. T. S. Davis, F.C.S., read a paper on preparing small quantities of gelatine emulsion, advocating the admixture of the silver and bromide salts in powder to the gelatine solution instead of previously dissolving them.—Mr. W. S. Bird read a paper on

the photography of vision, showing from researches made by M. Kuhne and Prof. Boll, that a visual purple pigment existed in the eye, and a theory therefrom of a result similar to that in photography, viz., a fixation of an image by physical changes in certain minute rods and cones found in some membranes of the retina, the experiments recorded tending to the old theory that the eye of a deceased person or animal retained the last visual impression.

Statistical Society, May 20.—Mr. Wm. Newmarch, F.R.S., vice-president, in the chair.—The paper read was by Mr. John B. Martin, M.A., banker, of Lombard Street, "On some Effects of a Crisis on the Banking Interest."

EDINBURGH

Royal Society, June 2.—Sir C. Wyville Thomson, vice-president, in the chair.—The following communications were read:—On the carboniferous volcanic rocks of the basin of the Firth of Forth: their structure in the field and under the microscope. Second paper, by Prof. Geikie.—Additional observations on the fungus disease affecting salmon, by A. B. Stirling, Conservator of the Anatomical Museum (communicated by Prof. Turner).—On the form and structure of the teeth of *Mesöplodon layardi* and *M. sowerbyi*, by Prof. Turner.

PARIS

Academy of Sciences, May 26.—M. Daubrée in the chair.—The following papers were read:—On the refraction of obscure heat, by M. Desains. With a view to getting lenses which will cause to converge to a point rays from the beginning and end of the dark spectrum, he tries to follow and recognise in dark spectra a given group of rays, spite of differences in the refringent and dispersive powers of the bodies employed, so as to reach the absolute value of the refractions of dark rays of given length in different diathermanous bodies. Hence may be calculated the radii of lenses of flint and crown glass, *e.g.*, which will give the convergence sought.—Chemical researches on the formation of coal, by M. Fremy. He concludes that coal is not an organised substance; it has taken plant impressions readily, because of its bituminous and plastic nature. The plants which produced coal seem to have first undergone *peaty fermentation*, which destroyed all vegetable organisation, and the coal was formed at expense of the peat, by a secondary action, produced by heat and pressure.—Determination of the difference of longitude between Paris and Berlin, by MM. Lœwy and Le Clerc. Astronomers of the two countries made simultaneous observations in contiguous tents, but with instruments and methods of their own choice. The principal differences of method are indicated. From the French observations (in one series of which M. Lœwy was in Berlin and M. Le Clerc in Paris, in the other *vice versâ*), the ultimate value of the difference of longitude with Cassini's meridian was 44m. 13·99s. (careful tests were applied). This showed a difference of 0·13s. with the German's result, which the authors think due to a slight variation of the optic axis in one or other of the instruments of either mission. From the various longitudes effected in Europe, several values of the longitude between Paris and Berlin may be deduced indirectly, and the authors hope, by discussing these numbers, to arrive at the true value.—On the distribution of work to a distance by electrical means, by M. Tresca. This relates to experiments made at some sugar works. A Gramme machine driven by a steam-engine, set in action another Gramme machine 400 metres or 650 m. off (as desired), and this latter rotated a drum with cable, which worked a double plough. An effective force of 3 horse-power was thus transmitted. The (copper) wire was formed of nine strands 1 mm. diameter, giving a section of 7 square mm. The first Gramme rotated 1,123 times per minute, the second 890.—On earthquakes which occurred in the East from the seventh to the seventeenth century, by M. Tholozan. According to the data obtained, Persia seems to have been most frequently attacked (the other countries are Mesopotamia, Egypt, Syria, Arabia, and Magreb); but one cannot draw very exact conclusions from the records. M. Tholozan, however, is able to contradict von Hoff's assertion that from the beginning of the thirteenth to the second half of the seventeenth century there was almost complete cessation of earthquakes in Syria and Judea; and Quatremare's, that the north-east of Africa has been almost always exempt.—M. Gyldén was elected Correspondent in Astronomy in room of the late P. Secchi.—On the characteristics of functions, by M. Jordan.—On a new representation of imaginary quantities, by M. Dupont.—New demonstration of the law of reciprocity, in the theory of quadratic residues, by M. Schering.—On the development of cot. x, by M. Le Page.—On the fluorescence of salts of earthy metals, by M. Soret. The liquid was placed in a quartz vessel, on which was concentrated, with a quartz lens, the light of the induction-spark passing, *e.g.*, between cadmium electrodes.—On the determination of calorific wave-lengths, by M. Mouton. The method was that of M. Fizeau, freed from the uncertainty resulting from ignorance of the law of dispersion of double refraction of the plate employed in calorific radiations.—On a peculiar mode of transmission of sound to a distance, by M. Decharme. One may, by a purely mechanical process, transmit 5, 10 . . . metres, the different sounds of a vibrating plate, a tuning-fork, or a stringed instrument, by putting these in communication, by means of metallic wires not stretched but in spiral, with suspended sheets of Dutc metal or tin (the fastenings are with wax).—On the diffusion of lithia and its presence in sea-water, by M. Marchand. He claims to have found lithia in sea-water before M. Bunsen did.—On the salts of guanidine, by M. Jousselin.—Experimental researches on the physiological signification of the terminal nervous plexus of the cornea, by M. Ranvier. The arrangement seems simply relative to the transparence of the cornea. The nerves themselves are nerves of general sensibility.—On the metamorphosis of cantharides (*Lytta vesicatoria*, Fab.), by M. Lichtenstein.—On the body-cavity of sedentary annelids, and their segmentary organs; some remarks on the genus Phascolosoma, by M. Cosmovici.—On the *Taenia giardi*, and on some species of the group of Inermes, by M. Moniez.

VIENNA

Imperial Academy of Sciences, March 20.—The following among other papers were read:—On *Cerianthus membranaceus*, a contribution to the anatomy of the Actinia, by Dr. von Heider.—Action of salt solutions on aldehydes (continued), by Prof. Lieben and Herr Zeisel.—On the formation of a rational plane curve of the third order on a conic section, by Prof. Weyr.—On the passage of light-rays in a homogeneous ball, by Prof. Lippich.—On the chemical composition of pyroxilin and the formula of cellulose, by Prof. Eder.—On the relation between heat-radiation and temperature, by Prof. Stefan.—Studies on ellagic acid, by Prof. Barth and Dr. Goldschmiedt.

April 3.—On the methods of investigating the polar actions of the electric current in striated muscle, by Prof. Hering.—On the polar actions of the electric current in muscles deprived of nerves, by Dr. Biedermann.—On phosphate of zinc, by Herr Demel.—On the solution of dynamical problems by means of Hamilton's partial differential equation, by Dr. Hocevar.—Contribution to a knowledge of copper chloride, by Herr Rosenfeld.—Geological description of North-east Thessaly, by Herr Teller.—On some points in geography and geology of European Turkey, by Dr. Boué.—Researches on the diffusion of salt solutions, by Herr Schulemeister.—On resorcindisulpho-acid, by Herr Tedeschi.—Action of melting caustic soda on aromatic acids, by Herren Barth and Schreder.—On derivatives of a phenoldisulpho-acid, by Herren Barth and Schmidt.—On a local influence on the magnetic observations in Vienna in the period 1860-71.

EVOLUTION, OLD AND NEW

Evolution, Old and New; or, The Theories of Buffon, Dr. Erasmus Darwin, and Lamarck, as compared with that of Mr. Charles Darwin. By Samuel Butler. (Op. 4.) (London: Hardwicke and Bogue, 1879.)

THE present work will not add to the reputation of the author of "Life and Habit." It is, nevertheless, an interesting and useful book, inasmuch as it gives a pretty full account of the theories and opinions of several authors whose writings are almost unknown to the present generation of naturalists. The sketch of the lives, and the numerous quotations from the works of the celebrated men named in the title page, are instructive and sometimes amusing. Quotations are also given from Mr. Patrick Matthew, Étienne and Isidore Geoffroy St. Hilaire, and Herbert Spencer, illustrating their views on evolution, and giving altogether a fair idea of the progress of modern thought on this important subject. But the main object of the book is to show that all these authors have been right, while Mr. Charles Darwin is altogether wrong; and that the works of the former contain a more philosophical, more accurate, and altogether superior view of the nature and causes of evolution in the organic world than those of the latter.

Mr. Butler finds in all the writers whose views he advocates, opinions which agree more or less closely with those so ingeniously and forcibly developed by himself, and to which full justice has already been done in the pages of NATURE (vol. xix. p. 479). No one can object to his adducing these points of agreement to fortify his own position, or to his arguing that his own hypotheses, thus supported, form an important and even a necessary supplement to the theory advocated by Mr. Darwin. But he goes much further than this, and maintains that the action of external conditions, combined with the desires and habits of animals, are the all-powerful causes of evolution, and that "natural selection," or "survival of the fittest," is comparatively unimportant, and is quite unworthy of the position given to it by Mr. Darwin and his followers. In doing this he not only falls into much confusion as to the phenomena of variation, but indulges in an amount of petty verbal criticism, quite unworthy of the high reputation established by his previous work; and I believe that naturalists in general will endorse the remark in my review of "Life and Habit" (which Mr. Butler has, apparently under the impression that this volume refutes it, placed in a conspicuous position on the fly-leaf of his book), that "the want of a practical acquaintance with natural history leads the author to take an erroneous view of the bearing of his own theories on those of Mr. Darwin."

In discussing the views and arguments of Buffon, Mr. Butler suggests that the numerous contradictory statements of this eminent writer are due to the necessity he was under of not arousing the enmity of the Church. He therefore adopts the method of directly contradicting himself whenever he has been a little too advanced. Over and over again he points out the evidence of the several families of animals and plants having each had a common ancestor, and he specially mentions the horse and the ass, man and apes, as having been thus derived. But he puts it all hypothetically, and then, to satisfy the Sorbonne and the public, he proceeds thus: "But no! It is certain from revelation that all animals have alike been favoured with the grace of an act of direct creation, and that the first pair of every species issued full formed from the hands of the Creator." These, and numerous other passages quoted, certainly support the theory that many of Buffon's statements are ironical; and that while himself a firm believer in the development of all organisms from common ancestors, he purposely contradicted himself sufficiently to prevent the suppression of his work as being opposed to religion.

Most interesting among the quotations from Buffon, however, are those which show how near he was to seizing upon the idea of "selection" as a means of modifying organisms. Thus he says:—"The dog is short-lived; he breeds often and freely; he is perpetually under the eye of man; hence when—by some chance common enough with nature—a variation or special feature has made its appearance, man has tried to perpetuate it by uniting together the individuals in which it has appeared, as people do now who wish to form new breeds of dogs and other animals." And again, in discussing the origin of our cultivated fruits, &c., he says: "It was only by sowing, tending, and bringing to maturity an almost infinite number of plants of the same kind that he was able to recognise some individuals with fruits sweeter and better than others." Here he clearly recognises the selection of individual variations as the source of varieties, and the necessity for breeding or growing on a large scale, in order to obtain such individual variations as are required. But he never laid hold of this idea with any firmness; for we find him elsewhere dwelling on the influence of change of climate, food, and treatment, as having produced the changes in domestic animals and cultivated plants; especially change of climate while accompanying man in his migrations, and the action of these changes on habits "influencing their natures, instincts, and most inward qualities."

We next come to Dr. Erasmus Darwin, of whose life, writings, and opinions a very interesting account is given, and who is an especial favourite of Mr. Butler on account of his views as to the transmission of memory and habit from parent to offspring, and as to the existence of sensation and voluntary motion in plants, although he laid more stress on imitation and instruction than on inherited habits, and in this departs widely from Mr. Butler. Dr. Darwin anticipated Lamarck in arguing that the transformations of animals "are in part produced by their own exertions in consequence of their desires and aversions, of their pleasures and their pains, or of irritation or of associations; and many of these acquired forms or propensities are transmitted to their posterity." He also had a glimpse of the mode of action of sexual selection; for, speaking of the spurs with which the males of many game birds are armed, and which they use in fighting, he says: "The final cause of this contest among the males seems to be that the strongest and most active animal should propagate the species, which should thence become improved." We cannot see, however, that he had any clear notion of the general action of the law of the

survival of the fittest, nor of the important part it necessarily plays in the accumulation and perpetuation of variations, however these may be caused. In this respect he was probably not so enlightened as Buffon.

Lamarck's writings are very largely quoted and his opinions fully illustrated; and we freely admit with Mr. Butler that, as a thorough and consistent evolutionist, he was not inferior to Mr. Darwin himself. But although he clearly saw the *fact* of evolution, and almost demonstrated the reality of the fact by a variety of arguments and a wealth of observation, yet, so far from adducing any adequate *causes* for evolution, he was actually inferior to his predecessors Buffon and Dr. Erasmus Darwin, since he appears to have had no glimpse of the way in which domestic races have actually been produced by human selection, and still less of the action of the law of the survival of the fittest on animals and plants in a state of nature. Everything he imputes to changed conditions and changed habits, developing new desires in animals and inducing new courses of action. He dwells much on the time required for these changes, and considers that we have a practically unlimited amount at our disposal, remarking that "a time infinitely great *qua* man is still infinitely short *qua* nature."

Lamarck is exceedingly vague in his statements as to the cause and mode of change. After describing the different kinds of locomotion, walking, leaping, flying, swimming, and the great need of these powers of movement to most animals, he adds: "Since, then, the power of locomotion was a matter affecting their individual self-preservation, as well as that of their race, the existence of the want led to the means of its being gratified." He does not seem to have perceived the struggle between individuals of the same species owing to their excessive numbers, but only the struggle between distinct races; as when he says: "The strongest and best armed for attack eat the weaker, and the greater kinds the smaller. Individuals of the same race rarely eat one another; they war only with other races than their own." He also refers to the excessive multiplication of the smaller kinds of animals, and shows how their numbers are limited, but he never observed that the race was thereby invigorated and might even be modified. He sums up his theory in the following three propositions:—

"1. That every considerable and sustained change in the surroundings of any animal involves a real change in its needs.

"2. That such change of needs involves the necessity of changed action in order to satisfy these needs, and, in consequence, of new habits.

"3. It follows that such and such parts, formerly less used, are now more frequently employed, and in consequence become more highly developed; new parts also become insensibly evolved in the creature by its own efforts from within."

These arguments are repeated in a variety of ways, and are applied to explain the origin of all our breeds of dogs and other domestic animals, as well as of all wild species; and he evidently had no notion that though these may be real causes, they would be utterly inadequate to produce any such effects as we see in nature without the accumulating power of natural selection. Mr. Butler, indeed, maintains that this power is implied in Lamarck's reasoning. He maintains "that one [of the most important conditions of an animal's life is the relation in which it stands to the other inhabitants of the same neighbourhood—from which the survival of the fittest follows as a self-evident proposition." And he adds: "Lamarck would not have hesitated to admit that, if animals are modified in a direction which is favourable to them, they will have a better chance of surviving and transmitting their favourable modifications."

But it is clear that Lamarck neither saw it nor admitted it; and his theory is therefore radically deficient. And he evidently sees this deficiency himself, for he says that frequent crosses with unmodified individuals will destroy the effect produced, and that therefore isolation is necessary.

We come next to Mr. Patrick Matthew, who in 1831 put forth his views on the development theory in a work on arboriculture; and we think that most naturalists will be amazed at the range and accuracy of his system, and will give him the highest credit as the first to see the important principles of human and "natural selection," conformity to conditions, and reversion to ancestral types; and also the unity of life, the varying degrees of individuality, and the continuity of ideas or habits forming an abiding memory, thus combining all the best essential features of the theories put forth by Lamarck, Darwin, and Mr. Butler himself. The following quotations illustrate Mr. Matthews's views:—"As the field of existence is limited and preoccupied, it is only the hardier, more robust, better-suited-to-circumstance individuals who are able to struggle forward to maturity, these inhabiting only the situations to which they have superior adaptation and greater power of occupancy than any other kind; the weaker and less circumstance-suited being prematurely destroyed. This principle is in constant action; it regulates the colour, the figure, the capacities, and instincts; those individuals in each species whose colour and covering are best suited to concealment or protection from enemies, or defence from inclemencies or vicissitudes of climate, whose figure is best accommodated to health, strength, defence, and support; in such immense waste of primary and youthful life those only come forward to maturity from the strict ordeal by which nature tests their adaptation to her standard of perfection and fitness to continue their kind by reproduction." He then goes on to show how this law tends to the production of almost uniform groups of individuals which we term species, and then adds: "This circumstance-adaptive law operating upon the slight but continued natural disposition to sport in the progeny, does not preclude the supposed influence which volition or sensation may have had over the configuration of the body." This, he says, is a matter to be inquired into, as well as "its dependency upon the preceding links of the particular chain of life, variety being often merely types or approximations of former parentage; thence the variation of the family as well as of the individual must be embraced by our experiments." These, and many other passages, show how fully and clearly Mr. Matthew apprehended the theory of natural selection, as well as the existence of more obscure laws of evolution, many years in advance of Mr. Darwin and myself, and in giving almost the whole of what Mr. Matthew has written on the subject Mr. Butler will have helped to call atten-

tion to one of the most original thinkers of the first half of the 19th century.

The last four chapters of the work are devoted to a critical comparison of the theories of Mr. Darwin with those of Lamarck, Dr. Darwin, and Buffon, greatly to the disadvantage (in Mr. Butler's opinion) of the former. Much of this criticism, however, is merely verbal, and is quite valueless; much of it, also, is founded on a confusion as to the meaning of such terms as "variation" and "variety," and on an inability to grasp the fact of the extent and universality of the individual variations of organisms; while another portion arises from taking the hypotheses of Lamarck as established facts. Of these several classes of unsound criticism we will give a few examples.

Mr. Butler first quotes (p. 339) numerous expressions from the "Origin of Species," referring to our great ignorance of the laws of variation, and our total ignorance of the cause of each individual difference; and then speaks of Lamarck "having established his principle that sense of need is the main direct cause of variation," and that variations thus engendered are inherited, which sufficiently accounts for all the facts. If Lamarck had "established" anything of the kind, Mr. Darwin and all evolutionists would certainly have followed him, but he nowhere proves or even attempts to prove his "principle," but merely states it as an "hypothesis" to account for facts which he saw no other way of explaining. Again, Mr. Butler himself says, that owing to the conditions of life being permanent for long periods—"The thoughts of the creature varying will thus have been turned mainly in one direction for long together; and hence the consequent modifications *will also be mainly in fixed and definite directions* for many successive generations; as in the direction of a warmer or cooler covering, &c. . . . It is easy to understand the accumulation of slight successive modifications *which thus make their appearance in given organs and in a set direction.*" The passages which I have italicised look like statements of fact—of what actually occurs; yet no such facts have ever been made known. If the law thus stated had been sufficiently effective to produce any permanent variations, breeders would sometimes have made use of it. Yet they certainly do not do so, whereas they do systematically and very successfully make use of selection. According to the above theory Australian sheep must have their thoughts constantly turned in the direction of less wool owing to the great heat of the climate, and a much larger proportion of each succeeding generation should have thin and scanty fleeces than occurs in England, especially in the tropical colony of Queensland, which, in proportion to its population, produces as much wool as the other colonies. If Mr. Butler could adduce, on good authority, such a fact as this, he would have some evidence in his favour, instead of which he can only make suppositions. The fantail and pouter pigeons, the crested Poland fowls, and all other strange domestic varieties, have been produced by selection of variations or sports which occurred among animals all subject to the same tolerably uniform conditions; while no proof has ever been given that anything more than very slight changes can be produced and perpetrated by change of conditions unaided by some kind of selection.

Mr. Butler's want of appreciation of what variation and natural selection really are, is shown by his referring to "the fact that *one* in a brood or litter, is born fitter for the conditions of existence than its brothers and sisters"—by his continually laying stress upon Mr. Darwin not having shown "how the individual differences first occur"—by his thinking that because natural selection is not the cause of "variation" it is therefore not the cause of "modification" or of a "variety" or "species"—and by his hardly ever referring to the enormous multiplying powers of animals, and the consequent extermination of a much greater number annually than the whole average living population. In my former article on the works of Mr. Murphy and Mr. Butler (NATURE, vol. xix. p. 477) I have shown how we may look at the whole population of a species at any given time as divisible, with regard to any one of its characters, into a more and a less developed moiety, and I believe that this mode of viewing the question will at once almost entirely remove the coincident-variation-in-the-right-direction difficulty, which forms the great stumbling-block of almost all the opponents of Mr. Darwin.

The difficulty as to the "cause of variation" also disappears from this point of view, for "variation" is seen to be synonymous with "want of perfect identity" between any two organisms, and this is clearly due to the almost infinite complexity of structure and minuteness of parts of all living things and the absolute impossibility that any two can have passed through an identical series of conditions or even had an origin in two identical germs. We see infinite variety arise in the inorganic world where there is a far less complexity of structure or variety of conditions. Even among the sands on the sea-shore no two grains are probably so nearly identical that a good microscopist could not detect a difference; while it is certain that nowhere in the world are there two hills or two rivers with any approach to complete similarity, though the entire process by which many of them have been produced must have often been almost identical. Variation, such as *always* occurs between the individuals of a species, is therefore an ultimate fact of nature which wants no further explanation than that we cannot even conceive it to be otherwise. We may indeed conceive more likeness on the average than actually exists, but we cannot really conceive of *perfect identity* between individuals formed and developed as are animals and plants. We may, on the other hand, seek for the causes of unusual or abnormal variation, and Mr. Darwin has suggested several. It is quite possible that those suggested by Lamarck and Mr. Butler may also be real causes, but they have certainly not been proved to be so; and even if they had they would not in the least affect the law of natural selection which *accumulates and perpetuates variations*, however they may have been produced.

The numerous verbal criticisms or quibbles in which Mr. Butler indulges are quite unworthy of his subject. When Mr. Darwin says, "Variation will cause the slight alterations," Mr. Butler remarks that this is the same as saying "Variation will cause the variations." Again, Mr. Butler maintains that the term "conditions of existence" is identical with or includes "survival of the fittest," which is identical with "natural selection." Therefore, when Mr. Darwin says "natural selection is

the main but not the exclusive means of modification," he must mean "the conditions of existence are the main," &c., &c.; therefore he really agrees with Lamarck, whose opinions he has called "erroneous!" Again, because Mr. Darwin has once used the term *nature*, metaphorically, for natural selection, our author seizes hold of it for a little ridicule, thus: "When, therefore, Mr. Darwin says that natural selection is the most important, but not the exclusive means whereby any modification has been effected, he is really saying that nature is the most important means of modification—which is only another way of telling us that variation causes variations, and is all very true as far as it goes." In the same style the use of the term "by *means* of natural selection" is criticised, and the use of "natural selection" at all, when "survival of the fittest" is admitted to be a more accurate term; and Mr. Butler seems to think that if the latter term were always used, a great deal of the force of Mr. Darwin's arguments would be lost. I venture to assert, however, that every argument can be stated with equal accuracy and effect, using only "survival of the fittest;" but there is this great advantage in using the term "natural selection," that it keeps before the mind the striking analogy and almost identity between the action of man and of nature in modifying species, an identity that was never seen by any of the older writers, but which was first clearly apprehended by Mr. Patrick Matthew, and first fully worked out by Mr. Darwin himself.

In the last chapter Mr. Butler takes the celebrated case of the Madeira wingless beetles to test the respective theories of Lamarck and Charles Darwin, and he could hardly have made a more unfortunate choice. According to Lamarck, he says, when a beetle found the wind taking it in a wrong direction, *which it knew would be fatal to it*, it ceased flying, and thus, by long-continued disuse, gradually lost its wings. Here we have the assumption that such insects as beetles know beforehand that if blown out to sea they will be drowned, an assumption for which not one particle of evidence is adduced, while, as every entomologist knows, pages might be filled with facts proving that insects of various orders do not possess any knowledge of the kind, but year after year go recklessly to their death by myriads.

Hardly less weak than this statement of the Lamarckian theory is the objection to that of Mr. Darwin, which is as follows:—"For Mr. Darwin cannot mean that the fact of some beetles being blown out to sea is the most important means whereby other beetles come to have smaller wings—that the Madeira beetles, in fact, come to have smaller wings, mainly because their large-winged uncles and aunts go away." Though Mr. Butler has tried to put this so as to look like an absurdity, it is strange that he cannot see that it contains an important truth. If the "large-winged" beetles go away, the small-winged remains to breed, and each succeeding generation will have, on the average, smaller wings than the last; and if, so long as any fly at all, the larger-winged continue to "go away," at last none will fly, and then, the wings being unused, will become abortive and rudimentary. As a crucial case, and to compare the power of the two theories as agents of change, let us suppose them both applied to the human inhabitants of Britain. First we will suppose all the men and women above the average height to go away year by year to Australia or elsewhere, while those under the average height remained. Does Mr. Butler doubt that at the end of, say, ten generations, the average height of English men and women would have been considerably reduced? This would be selection pure and simple. Now for the Lamarckian theory. Let all the people be taught (and believe) that to be short is to be beautiful and virtuous, and let all doors and all public vehicles be made low to suit short people and inconvenience tall ones, and moreover, let short people alone be eligible for a number of posts of honour and dignity, there would thus be created a general desire to be short oneself and to have short children, and the Lamarckian principle would be brought fairly into play. Now supposing that no artificial selection of any kind was practised, and that, owing to the prevalence of high moral principle, the health, lives, and affections of tall people were valued and cared for as much as those of their more favoured short fellow-countrymen, does Mr. Butler seriously maintain that at the end of ten generations any perceptible effect would be produced on the average height of the people; or that anything like the same amount of effect would be produced as by the other experiment? But if not, then "selection," whether natural or artificial, is the *main cause* or *means* of modification; the plain reason being that it accumulates differences which actually exist, whereas, by the other mode, you must produce an increase or diminution of these differences by causes which have not been proved to act at all, and which, even if they do produce any effect, can only do so with extreme slowness.

In conclusion, then, we may admit the possibility that the causes of variation adduced by Lamarck, as well as those so well set forth by Mr. Butler in his "Life and Habit," are real causes; we may further admit that some or all of these causes are essential to the origin and development of the more important organs of animals, and that they constitute the chief supplementary agencies the existence of which Mr. Darwin himself recognises; but, even admitting all this, we still maintain that they would be all powerless to effect great or permanent modifications without the accumulating action of natural selection, which may therefore be truly described as the "means" by which alone the "origin of species" has been actually brought about.

ALFRED R. WALLACE

OUR BOOK SHELF

Elementary Arithmetic and How to Teach It. By George Ricks, B.Sc. (London: Isbister, 1879.)

MOST school-books, especially those of an elementary character, are mere poison, and very disagreeable poison too. But Mr. Ricks has supplied us in this volume with really healthy food. We heartily recommend it to all young teachers, and believe, moreover, that many who deem themselves experienced may obtain from it several useful hints. In Part I. the teacher of an infant school is shown how to proceed with his pupils; in Parts II. and III. similar information is afforded to the teacher in a junior school; Parts IV. and V. relate to senior schools; Part VI. is devoted to advanced scholars. We have discovered nothing very remarkable in the latter half of the book; indeed, Mr. Ricks seems to get a little beyond himself as soon as he advances from the juniors to the seniors. This, however, is a matter of small consequence.

It is the elementary part of a subject which is always so badly taught, chiefly because it is a general belief that any one can teach a child. We are, therefore, pleased to welcome in Parts I., II. and III., an exceedingly clear statement as to what sections of arithmetic should be taught, and how they should be taught to young children.

LETTERS TO THE EDITOR

[*The Editor urgently requests correspondents to keep their letters as short as possible. The pressure on his space is so great that it is impossible otherwise to ensure the appearance even of communications containing interesting and novel facts.*]

A Machine for Drawing Compound Harmonic Curves

IN NATURE (vol. xx. p. 103) there appears an abstract of a paper by Prof. E. W. Blake on a machine for drawing compound harmonic curves. Prof. Blake is doubtless not aware that this machine is based on a plan proposed by Prof. Perry and myself in our paper on "the music of colour and visible motion," read before the Physical Society, November 23, 1878. In that paper, after the description of our own motion-compounder, will be found the following :—"But it is possible that in our new machine we shall adopt a totally different plan, and one which we think is new. If the two extremities of a long rigid rod have parallel motions perpendicular to the rod, the middle of the rod has a motion equal to half the sum of the extremities. Thus the parallel motions of 2, 4, or 2^n points may be compounded. Similarly for 3 points, one-third of the sum of parallel motions is obtained from the centre of a rigid triangular piece of which the points are the corners; so that by bars and frames of simple construction it is easy to get the sum of the parallel motions of any number of pieces."

But I think that this method which we suggested, and which is the one now described by Prof. Blake, is inferior to the roller-cam principle employed by us in the instrument we constructed, and explained to the Physical Society, in that with the latter in its complete form we can alter, while the machine is actually in motion, the *amplitude* as well as the *phase*, by any *desired* amount, of *any one* of the component vibrations. This facility, although not possessed, as far as I am aware, by any other motion compounder, is extremely desirable for the varied description of compound curves, whether these curves be merely intended, as in the ordinary forms of such instruments, to show the resultant of two or more vibrations, or be designed, in accordance with the plan of Mr. Perry and myself, to work on the emotions, in the rendering of a new genus of music, by the varied, yet controlled, motions of the body, or bodies, describing these curves.

W. E. AYRTON

Lightning Conductors

ON the night of Wednesday, May 28, shortly after ten o'clock, my father's house at Caterham, in Surrey, was struck by lightning. We had not noticed any thunder before going to our bedrooms, but shortly after doing so we saw a very vivid flash, followed by thunder after an interval of perhaps five seconds; three or four minutes after this there came with a terrific crash the flash which struck the house, and afterwards no more thunder or lightning sufficient to attract our attention while we were intent upon investigating the mischief done.

The house stands high, upon a hill upwards of 700 feet above the sea; it is somewhat higher than any house or other object in its immediate vicinity. Roughly speaking, it may be described as a square block surmounted by a steep tiled roof, the ridge of which runs north and south, and astride upon the ridge stand two chimney stacks of equal height; from one corner of the square block runs away an extension, the roof and chimney stacks of which are upon a somewhat lower level.

Upon the northern chimney stack, at its eastern end, was the lightning conductor, which consisted of the usual hollow rod (½ inch) at the top, continuous with a flat plaited rope of copper and zinc wire (1 inch in width), carried through glass insulating rings along the slope of the roof, over the rain-water gutter, and down the side of the house into the ground.

The flash first struck the lightning conductor, hurled the rod down, and shattered the chimney-pots and a little of the brick-work; it seems to have followed the chimney-stack down to the ridge of the roof, and there to have divided. That portion of the discharge which passed down the eastern slope of the roof seems to have followed the chain portion of the lightning conductor as far as the rain-water gutter (iron); this it slightly broke, and broke also two panes of glass immediately beneath it, but this portion of the flash could be traced no further, and dead leaves, &c., about the remainder of the lightning conductor would seem to indicate that none had passed down that, at least not any large quantity.

The greater part of the discharge seems to have utterly left the guidance of the conductor, and to have first followed the lead flushing of the chimney stack down the western slope of the roof; a foot or so below the end of the flushing the roof was perforated, and the tiles broken and thrown down; thence, without any disturbance of the intervening tiling the discharge leapt a distance of some 15 feet, perforated horizontally a 9 inch-brick wall, covered on its exterior by weather tiling, and so reached an iron water cistern immediately within this wall. The woodwork about the cistern was started, but not much splintered; thence the discharge passed downwards by way of the water pipes, down two stories to a force-pump in the scullery, and thence, probably, by the pipes, down into the subterranean water-tanks.

But the pump in the scullery was provided with a pipe and tap over the sink, and there was also a small "tell-tale" pipe from the cistern above, designed to show when the cistern had been filled. This also terminated over the sink. Along these some part of the discharge was led, and not being safely conducted away, threw down and shattered the slate about the sink.

The perforation in the brick wall was circular, large enough to easily admit one's finger, and was blackened on its interior; when first found, eight or ten minutes after the occurrence, it was still quite hot.

The practical question that presses for an answer is, what did the lightning conductor do for us? Its selection as the point struck seems as though it brought the discharge upon the house; certainly it, although I believe of the usual construction, was utterly inadequate to carry off, or even direct the course of, the discharge, for a most copious and violently destructive discharge passed altogether from it and down over the opposite or western slope of the roof.

On the other hand, the iron water-tank and its pipe system proved adequate and safe conductors of the electric fluid, which left not the smallest trace of its passage along them until it reached the scullery sink, and there would presumably have done no harm, had it not been for the existence of the tap pipe, which led a portion of it astray. And on both faces of the house the iron gutters and rain-water pipes seem to have proved efficient conductors, for no violently destructive effects were manifested, save the breaking of two panes of glass after the electric fluid reached them. But as I am no electrician I can add nothing useful to the bare narration of the facts. I should add that the soot was very completely and violently ejected into the rooms from the chimneys of the stack struck.

CHARLES S. TOMES

P.S.—Subsequent closer examination of the portions of the lightning-conductor showed that there were traces of fusion of the hollow copper rod at its junction with the rope which had been inserted into it; the sectional area of copper here available for carrying the discharge seems to have been less than that in either the rod or the rope. Slighter traces of fusion existed here and there in the whole length of the rod. In its passage round the water-gutters the discharge cracked each one at its junction with the next segment; that is to say, the iron was cracked wherever the interposition of a little red lead to make the joint tight offered increased resistance to its passage, and the lead flushing of the roof was fused below the perforations in the brick wall, indicating that the whole discharge did not go through the wall to the iron water-tank.

THE effects produced by the recent thunderstorms are so interesting and instructive that I think it worth while to record the results of investigations which I have made personally or had made for me.

On May 31 there was published in the *Times* particulars of the damage done to the church at Laughton-en-le-Morthen, and the conductor was described as a thin corrugated tube of copper made

in sections, apparently fastened together, but in fact disconnected and with bad earth contact.

A disastrous result followed the use of a similar conductor in the case of Mr. Osbaldiston's house near Sheffield, in the storm of Tuesday, the 5th instant, when his house was completely wrecked.

Here the flash, after coming partly down the tube and breaking the worse than useless insulators, left the conductor about nine feet above the ground, and passed through a thick wall to the gas-pipe, behind the drawing-room mirror, which it smashed to atoms, broke some Sèvres vases on the mantelpiece, melted the gas-pipe and set fire to the gas, destroyed the gilded ceiling and cornice, ripped up the floor above, destroyed the furniture, and in short did damage estimated at about 500*l*.

In this case the lightning having left the conductor to go to the gas-pipe shows that the corrugated tube contained too little metal—though it was seven-eighths of an inch in outside diameter, and that the earth contact of the tube was not so good as the gas-pipe.

The next case which I have had examined was Mr. Tomes's house at Caterham, which was struck on Wednesday, May 28, about 10 o'clock P.M. The supposed conductor here was a woven band about an inch wide, made of twelve small copper wires, with two zinc wires interwoven! forming a worse conductor than the copper tube. The top terminal appears to be made of a soft alloy of tin and zinc, with a small steel wire in the centre! This was fastened on to a thin copper tube measuring half an inch outside and about six feet long.

To the lower end of the tube the band was attached, and here again the abominable glass insulators were used. The tube was fixed to a chimney and the band carried over the roof, coming in contact with the iron water spout on its way down. The end of the band was simply struck into the chalky soil to a depth of about a foot, so that it formed a very bad earth contact.

The lightning struck the point (the alloy round the steel has been melted or broken off some time ago, for the steel point is rusty), and passed down the band to the iron water-spout, which went round the eaves of the roof till it came to some lead flushing on the other side of the house away from the conductor; it then went up the lead, which it partially fused, and entered a small water-cistern in the attic, which luckily was connected by an iron pipe leading to a large iron tank under the ground, which thus formed an admirable earth contact. The distance to the conductor to the top water-cistern was about fifteen feet.

The damage done in this case was limited to little more than breaking two panes of glass and the glass insulators, and it proved that the band did not form an efficient conductor.

The third case which I have to report occurred on the same afternoon as that at Sheffield. The church of Saint Marie, Rugby, was struck, and might have been burned to the ground, had not the workmen employed in repairing the spire taken shelter in the church from the coming storm. They had been on the top and saw a dense black cloud approaching, and luckily came down, and had not been long in the church which, at 3 P.M. was so dark that they could scarcely see each other at a distance of a couple of yards, when a terrific crash was heard, and as suddenly the gas under the organ loft was lighted and the woodwork began to blaze. The men got the fire extinguished, and found that the lightning had melted the soft metal gas-pipes at a T-piece joint.

The spire is 212 feet high, and when it was built a conductor of copper-wire rope half an inch in diameter had been fixed. This has been repaired at the top by the present contractor attaching to it about fifty feet of rope of seven-eighths diameter. No insulators had been used, and so far as could be ascertained by a short inspection, the conductor appeared complete.

About half way up the spire there is a peal of eight bells. These have iron wires about one-eighth of an inch diameter leading from the clappers down to the back of the organ loft, but terminating in the spire a short distance from an iron gas-pipe about one inch in diameter fixed against the wall of the organ loft.

In this case I think that the rope conductor carried off part of the flash, and that part came down the bell-wires and went through the wall to the gas-pipe, for part of the stone wall next the organ, about a foot in diameter, was exploded off and thrown into the organ loft. The flash then partly ran along the iron pipe and melted the soft metal pipe, which is three-quarters of an inch diameter and a sixteenth thick, and set fire to the gas, and the remainder of the flash went to earth.

It was fortunate that no one was working the chimes, for if he had he would certainly have formed part of the circuit and been killed. The church, however, escaped with very slight damage.

R. S. NEWALL

Bud-Variation in Bananas

IN my garden there is a large plant (planted about eleven years ago) of a variety of banana, distinguished by purplish stems and petioles, red fruits, and by a very peculiar flavour of the latter. From the centre of this plant, covered by the rotten stems of former years, there are now growing green stems, with green petioles; one of them has already produced fruits, which were green when immature, and yellow when ripe, and the flavour of which I found to be but slightly altered. All the young stems growing from the circumference of the plant are purplish.

May not many of the varieties of bananas have been produced by bud-variation?

FRITZ MÜLLER

Itajahy, April 7

Fertilization of Erica carnea

ALL our Vaccinieæ and Ericaceæ, with tubular corolla, as far as hitherto known, are adapted to cross fertilization by Apidæ; for instance, *Vaccinium myrtillus* and *Vitis idæa*, *Arctostaphylos uva ursi* and *Erica tetralix*. I was, therefore, much struck yesterday by the observation that *Erica carnea* is abundantly visited and cross fertilized by a butterfly, *Vanessa cardui*, but not by a single bee. And, indeed, the colour and structure of this flower corresponds far more to the taste and habits of butterflies than of Apidæ. Like all other alpine flowers adapted to butterflies (*Saponaria ocymoides*, *Silene acaulis*, species of Dianthus, etc.), *Erica carnea* is also of a gay red (pink) colour, and its inclined tubular corolla is so narrowed downwards that its small opening is almost completely occupied by the anthers projecting from it. Hence butterflies which are most distinctly attracted by the colour of this flower, as also by its structure, are alone able easily to insert their thin proboscis into its corolla and to reach its honey.

Wherever in a sunny place of the Albula Valley *Erica carnea* is in full flower, and I observed more than thirty such places yesterday and to-day, *Vanessa cardui* is frequently found visiting and fertilizing it—so frequently that sometimes five or six specimens are visible at the same time.

HERMANN MÜLLER

Bergün, in the Albula Valley, June 3

Early Sun-Spot Records

To the very small number of non-Chinese observations of solar spots prior to the invention of the telescope we may add one, which I find in the voyages of Henry Hudson, published by the Hackluyt Society. He appears to have noticed such a phenomenon on March 21, 1609. Hudson says, "Then we observed the sunne, having a slake, and found our heigth to bee 70 deg. 30 min." A note says, the word slake, as a substantive, seems to be a north country word, meaning according to Brocket "an accumulation of mud or slime from slijck, cœnum, lutum." It will be remembered that there is a paper by Mr. Williams, the late Secretary of the R.A.S., on Chinese observations of solar spots in the monthly notices for April 1873. Mr. Williams's translation records forty-five such between the years A.D. 301 and 1205 inclusive. It will be seen that this list does not correspond with that given in Mr. Hosie's communication to NATURE of June 5. In the above interval Mr. Hosie records twenty-four spots not mentioned in Mr. Williams's paper; and in the latter there are nine recorded that do not occur in the longer list of Mr. Hosie. The number of naked eye records of sun-spots that may be brought to light will never be sufficient to carry back Dr. Wolf's sun-spot periods previous to the introduction of the telescope. There is, however, another Chinese record that it would be interesting to see translated. Mr. Williams, in the paper referred to, says, "these observations are continued in the supplement to Ma Twan Lin's Encyclopædia," and that he had found in the history of the Ming dynasty many observations of solar spots, the latest being November 29, 1638.

Upton Helions Rectory, Crediton, June 9

A Meteor and the Weather in New Caledonia

According to my promise to send you accounts of any remarkable meteors that I may see here, I now notify one which appeared yesterday evening, April 13, at 20 minutes past 6 P.M. We were driving slowly home from Ansevata, near Noumea, when a splendid brilliant *pure white* meteor fell from the zenith, about 30°, quite perpendicularly and slowly. It burst into three pieces, and instantly disappeared. From Noumea its direction was due south, and in size it appeared four or five times larger than Venus. We heard no noise; the sound of the carriage wheels grinding on the road would have prevented any but a rather loud one being audible. It was not dark, but twilight.

We have been suffering much from unusual heat, and the atmosphere is surcharged with electricity. Heavy storms brew in the mountains, but we have been free from them here in Noumea. Heavy rain squalls gather to the southward, and on reaching the south point of New Caledonia either divide and run along the mountains on one side or the circling reef on the other, or also pass solidly in either direction, leaving the peninsula of Noumea perfectly dry. E. L. Layard

Brit. Consulate, Noumea, April 14

Intellect in Brutes

Mr. Romanes has alluded to some of the peculiarities of my feline pets, but really those are by no means the most striking instances of their intelligence. My wife and I are devotedly fond of our cats, so much so as to afford amusement to our friends, and we are never tired of expatiating on their indications of intelligence. A pedigree book is kept, and any reader of Nature desirous of possessing a kitten of an intelligent stock is welcome to one on three or four months' notice.

I wish to give one other story of them which seems to show that they are apt to indulge in revenge and to act in systematic co-operation to accomplish it. They are of very cleanly habits, and, save under the circumstances about to be narrated, have never given any trouble in this respect. But some time ago we had a visitor who had a strong and very badly-concealed dislike to them. The dislike was quite mutual. Very soon after the arrival of this visitor the cats became very objectionable on account of messes, and these were concentrated in and near the bedroom occupied by the object of their aversion. Their insanitary proceedings became so pronounced that it almost appeared as if they had invited all their feline friends in the neighbourhood to join in the establishment of a "night-soil tip." No amount of correction, aided by pepper of the most pungent kind, could stop it, and I most reluctantly determined upon a wholesale felicide. The visitor departed, however, before this was carried into effect, and immediately the nuisance ceased, and our cats resumed their original cleanly habits.

Lawson Tait

I have perused with interest the admirable summary of the "Animal Intelligence" question by Mr. Romanes. On reading the article in question, it occurred to me that I had at hand some memoranda concerning animal intelligence which bear on the presence, not merely of *abstract* reasoning in dogs, but also upon the presence in dogs of traits of character remarkably resembling those we are accustomed to name "retaliation" and "revenge" in man. I now send you the jottings in question, obtained, I may add, from personal friends. About thirteen years ago, a now deceased medical man residing near Edinburgh, possessed a favourite collie, "Cheviot" by name. The incident I am about to relate, I may mention, was related to me by the son of the gentleman in question, both father and son, along with a perfectly disinterested party, having corroborated the facts. The then provost of the burgh in which "Cheviot" resided, had issued an interdict against unmuzzled dogs during the "dog days," and "Cheviot" submitted with no good grace to the operation of securing his jaws. Frequently "Cheviot's" master and the members of the family spoke in the dog's hearing, in no measured terms of the cruelty of the provost's order. But the end of the "dog days" came, and "Cheviot's" muzzle was removed. On the afternoon of the day of liberation, the provost called on "Cheviot's" master, to say, that in the morning he had heard a dog whining at his front door. The provost opened the door; "Cheviot" was in waiting, his muzzle in his mouth. One look at the provost, and the muzzle was dropped at his feet, "Cheviot" scampering off in the highest glee, as if delighted to have had the opportunity of laying the cause of his grievance at the door of his enemy.

The details were vouched for by the provost himself, also a medical practitioner in the burgh.

Here it seems to me you possess an incident of dog character explicable only on the supposition that there are germs in the canine philosophy of acts and traits fully developed in ours.

Incident number two deals with the doings of a retriever, some four or five years old, who, whilst bearing an implacable enmity to felines at large, had struck up a close friendship with a household cat, which, from kittenhood, had been associated with him. For sanitary reasons the cat was condemned to die. According to the orthodox method, puss was placed in a sack weighted with stones, and carried to the sea, "Keeper," the dog, following in the wake of the procession. The cat was duly thrown into the sea, "Keeper" waited to see if it would rise, but on seeing no signs of his feline friend, he at once dived for the sack, and landed it at an adjacent pier. Being met by the executioners and divining that puss was yet in danger, "Keeper" re-entered the water, sack in mouth, and swam across the bay to a point of safety, and landed his burden. Puss was spared in deference to "Keeper's" anxiety.

I can find still another example of extreme unselfishness in a mongrel dog, who, for some years before the death of an old deaf and blind companion, was accustomed to proceed to his resting-place, and bark in his ear to warn him of the presence near at hand of the milk which the kindly hand of the mistress of the house was accustomed to place for the delectation of both. This proceeding was repeated day by day, with unvarying regularity, and in its nature suggests strongly that the exercise of self-denial—amidst the obvious temptation of an easy acquirement of luxury—has to be placed to the credit account of the canine race. Andrew Wilson

Edinburgh Medical School, June 6

With reference to the article in Nature of 5th June, permit me to narrate an instance of "abstract reasoning" in a retriever that I was witness to last autumn.

Having shot a hare so slightly as to make it a long chase for the dog (a young one), I watched the retriever follow the hare over the open hills of Aberdeenshire for upwards of two miles until the chase was lost to view under a stone dyke. In a few moments the dog was observed to carry something in his mouth with which he disappeared over the dyke into a turnip field. "He has killed the hare and he is too tired to bring it back, so he is burying it," quoth the keeper, "we shall come up with it in the evening." The day's sport over, we made for the dog's burying ground, but the retriever, if you please, knew nothing about it; and careered wildly about in every direction except the right one. The keeper, Henry Ledingham of Tarland, Aboyne, having a remarkable gift of spotting fallen game, actually put his foot on the very spot among the turnips where the burial had occurred. After immense affectation of surprise the retriever was forced to unearth the hare. The hare, however, was a rotten old carcass of a hare, with no eyes and teeth, that the retriever had picked up and buried to save himself the pains of following the live hare. Perfectly conscious of his misdeed, the dog had given evidence of abstract reasoning in each stage of the transaction.

Charles Baillie Hamilton

St. Stephen's Club, Westminster, June 10

I have followed the discussion in your columns on "Intellect in Brutes" attentively, and I maintain that Mr. Henslow's distinction between man's power of abstract reasoning, and the reasoning of animals from objects present to the senses (a faculty they certainly possess, if the theory of deductive reasoning, that all inference is from particulars to particulars be accepted, which, however, cannot be proved), is perfectly valid, in spite of any accidental errors of illustration.

The fact that a cat or a dog subject their food to examination before eating it, does not most assuredly prove the possession of abstract powers of thought in the animal. Mr. Romanes here says:—"The motive of the examination being to ascertain which general idea of quality is appropriate to the particular object examined."

Here he attributes to an animal whose nature he does not fully understand his own process of thought, and this appears to me to be a constant source of error in the investigation of animal psychology. That brutes possess self-consciousness, introspection, imagination, abstract thought, cannot, I think, be proved. The

fact that animals possess faculties differing from those of man is an insuperable obstacle to a perfect analysis of their intelligences.

Name these faculties as you please, call them "inherited habit," "inherited memory," it is perfectly certain that man does not possess them.

H. D. BARCLAY

WILLIAM FROUDE

THE death of Mr. W. Froude, F.R.S., is a loss to science that cannot well be estimated. For many years he laboured with great ability and success in a field of research that was beset with difficulties, and had previously been almost barren of results. He was educated at Westminster, and went from there to Oxford, where he distinguished himself in mathematics. After leaving Oxford he became a civil engineer, and assisted Mr. Brunel in railway and other engineering work. He retired from active professional life in 1846, but his love of applied science retained such a hold upon him that he never ceased to occupy himself with important scientific investigations, and the solution of practical problems of peculiar difficulty. His intimacy with Mr. Brunel led to his mind being directed towards the study of those laws of nature which govern the motion of floating bodies. Mr. Brunel had devoted himself, among other things, to the improvement and development of iron steamship construction. In the *Great Western* and *Great Britain* he had made great advances in this direction; while in the *Great Eastern* he showed that iron and steam power could be employed in the production of ships of practically unlimited dimensions, and that by means of these agencies all the advantages appertaining to increased size might be realised.

In designing ships of such exceptional character and dimensions, Mr. Brunel found little to guide him in judging of their behaviour at sea. They were so different to any vessels afloat whose behaviour and qualities might have been ascertained, that he was unable to appeal to experience, while the light of science was so feeble and doubtful as to afford him no aid. Nobody at that time knew anything of the laws upon which a ship's motion at sea depends. There was a large mass of traditional experience, but this was often at variance with fact, owing to phenomena which are familiar to seamen being regarded as absolute, and possessing a reality of existence as well as of appearance; while, as must be obvious, they are only relative in their character, and cannot be accurately defined without making due allowance for the position and motion of a ship, with reference to the sea. The rules and maxims that had been adopted upon such incorrect and distorted data, were either unimportant or misleading; they were of no value. Mr. Froude said, quite correctly, in 1861, that our shipbuilders, while extending their knowledge in other directions, seem to have guided themselves by rhetorical phrases or random speculations in this particular branch of their art, "so that when a new ship is sent to sea, her constructor has to watch her behaviour in a seaway, with as anxious and uncertain an eye as if she were an animal he had bred and was rearing, and hoped would turn out well, not a work which he had himself completed, and whose performance he could predict, in virtue of the principles he had acted on in its design."

Mr. Froude, at the request of Mr. Brunel, commenced in 1856 an investigation into the laws of motion of a ship among waves. This had been previously attempted by D. Bernouilli, Euler, Moseley, and others, but without success. None of these writers had realised the fundamental conditions of the action of wave-water upon a ship, viz., that the direction and intensity of the fluid-pressure at any point is continually changing, and that the direction of pressure is normal to the surface of equal pressure passing through that point. They based their theories upon hypotheses respecting wave-action that were all more or less erroneous, and prevented any useful result being realised. Mr. Froude's method of dealing with the subject was, first of all, to determine the manner in which a wave acts upon a ship; or, in other words, the mode of operation of the agency whose effects he wished to comprehend. In this he was completely successful, and proved in an unexceptionable manner the mechanical possibility of that form of motion known as the trochoidal sea-wave. On the assumption that the motion of each particle on the surface of a wave describes an exact circle, whose diameter is the height of the wave from hollow to crest—which agrees with the results of observation—and that the motions of all particles lie in vertical planes which cut the wave-ridges at right angles, he deduced the theory that the form of the wave would be trochoidal, and that the periodic time would be equal to the time occupied by a heavy body in falling through a height equal to the circumference of a circle whose diameter is the length of a wave. It also followed that all sub-surfaces of equal pressure would be trochoids of the same length as the surface-wave, but of a height which would diminish with the depth in accordance with the equation $\frac{r_o}{r_d} = e^{\frac{\pi}{L}d}$, where e is the base of Napierian logarithms, L the length of the wave from hollow to crest, d the depth of the centre of the circle described by any particle below that of the circle described by the surface-particle, r_d the radius of the circle at the depth d, and r_o that of the circle at the surface. Prof. Rankine also independently deduced the same theory. A striking feature of the investigation was the rapid decrease in the motions of the particles as they are traced to lower depths. Prof. Stokes showed that for all waves of ordinary proportions, the motion at a depth equal to the length of the whole wave from crest to crest is only $\frac{1}{535}$ of that which belongs to a surface particle. The dynamical conditions of wave-water being thoroughly investigated and established, Mr. Froude next proceeded to base upon it a scientific theory of the rolling of ships among waves.

The subject was first brought before the public by Mr. Froude in a paper read before the Institution of Naval Architects in 1861. He stated that he felt some diffidence in bringing forward "what assumes to be a tolerably complete theoretical elucidation of a difficult and intricate subject, which has hitherto been treated as if unapproachable by the methods of regular investigation." He pointed out that the characteristic feature of the dynamical laws to which it would be necessary to refer the movements of a ship when rolling is the gradual accumulation of angle during several successive rolls, the cumulative action thus growing up into a maximum, and then dying out by very similar gradations until the ship becomes for a moment steady, when a nearly similar series of excursions commences and is reproduced; while in reference to the momentary pause, or cessation of motion, it seems clear that it occurs, not because the waves themselves cease, or cease to act, but because the last oscillation has died out at a moment when the ship and the waves have come to occupy, relatively, a position of momentary equilibrium. This is so closely analogous to what happens when a pendulum is subjected to a series of impulses, partially synchronous with its own excursions, that it seemed probable that the laws which govern the latter class of phenomena would be found, *mutatis mutandis*, applicable to the elucidation of the former also. The investigation of the laws of rolling motion, when thus regarded, therefore assumed the form of the inquiry, "What is the cumulative result of the continuous action of a series of consecutive waves operating on a given ship?"

In order to determine this it was necessary first to determine how each individual wave will act upon a ship at each instant of time; or, in other words, "What is the position of momentary equilibrium for a body floating on a wave, and what accelerating force towards that position

will the body experience in terms of her momentary deviation from it?" Mr. Froude has demonstrated both *à priori* and experimentally that to a stabilised particle floating at any point on the upper surface of a wave, the position of momentary equilibrium is that which would place the axis of equilibrium normal to the wave surface at the point where it floats, and that to another similar particle, floating or suspended below the surface, the position of momentary equilibrium is that which would place the axis normal to the sub-surface of equal pressure passing through the point where it is placed. If we take account of the aggregation of particles which a ship displaces, and for which she herself is substituted, and of which she accepts the aggregate dynamic condition, we know that her position of momentary equilibrium must be the mean of the positions belonging to the various particles displaced; and we may assume, with a close approximation to the truth, that this is the position which would place her axis of equilibrium, or her masts, at right angles to one of the wave sub-surfaces of equal pressure.

The sub-surface of equal pressure through the centre of gravity of a ship's displacement may be regarded in theory as a sufficiently close approximation to the effective wave surface; and it follows that when a ship deviates from the normal to this surface the effort by which she endeavours to conform to it depends upon the momentary angle of deviation in the same manner as her effort to assume an upright position when inclined in still water depends on the angle of inclination. Hence her stability or effort to become vertical in still water, measures her effort to become normal to the effective wave surface in wave water. The equations of motion for a floating body, oscillating in still water, which had previously been investigated, could therefore be applied to undulating water by introducing the condition that the position of equilibrium changed with the direction of the wave slope. Mr. Froude was not able, at first, to solve the resulting equation by adopting the trochoidal hypothesis. He therefore substituted the curve of sines for the trochoid, which gave him a form of equation he could deal with. Prof. Rankine afterwards solved the equation obtained by using the trochoid, but the results agreed with those arrived at by Mr. Froude under the conditions to which the investigations applied.

The assumptions made in order to adapt the problem to mathematical treatment were (1) that the ship is rolling passively in the trough of the sea; (2) that she is exposed to a regular series of similar waves; (3) that the waves are so large as compared with the ship that she may be assumed to accept the motion of the part of the wave she displaces; (4) that the variations of apparent weight may be neglected in comparison with the actual weight; (5) that the ship is of such a form as to make her still water oscillations isochronous—this being approximately the form of the old line of battle ships; and (6) that the rolling is unresisted—the effects of resistance in modifying the motion being separately considered.

The equations thus obtained by Mr. Froude, representing the oscillations of a ship among waves as compared with those performed in still water, are most interesting; but our space will not admit of giving a full analysis of them. Their general character may, however, be appreciated if we call attention to some of their most striking features.

One critical case is that of a ship rolling among waves, whose periodic time synchronises with her own time of oscillation. It may be readily deduced from Mr. Froude's fundamental equations that, if it were not for the resistance to rolling caused by surface friction and form, a ship placed broadside on to waves which have her own periodic time, must ultimately roll completely over, however small the wave may be. It is not uncommon to find the length of a half-wave ten times the height. Such waves would increase the angle of roll by 14·1° at each inclination, so that six successive impulses, or three complete waves, passing a ship would produce almost a complete overset. Though this conclusion requires to be greatly limited by introducing the element of resistance, it is obvious that such synchronism of wave-period and ship's-period must produce most formidable effects. Mr. Froude produced the result thus indicated by his theory by direct experiment with floating bodies of such form as would give approximate cases of unresisted rolling. He immersed a sphere to two-thirds of its radius; a prolate spheroid to about the same proportion of its major axis; and a body like a flattened orange was wholly immersed, having only a very narrow neck projecting from it above the water-level, like the stem of a hydrometer. By an ingenious arrangement for regulating the period of the waves it was found that, when the oscillations of the floats and the wave-period were made to synchronise, all the floats were upset after the transit of a very few waves, while a very small change in the natural period of one of the floats, made by slightly altering the position of its centre of gravity, made its behaviour plainly exceptional as compared with the two others. It now refused to be completely overset by the series of waves which would upset the two others almost at the same moment, though it was itself overset by a series slightly quickened or retarded according as its own period was quickened or retarded by the altered position of its centre of gravity, the other two being at the same time released from all danger of capsizing.

Another critical case is when the ship possesses infinite stability; or an infinitely small radius of gyration or moment of inertia. This is not a practical possibility, but is noticed on account of the indication it gives of a ship's tendencies according to the degree in which it may possibly be approached. In this case the ship will be perfectly quick in her movements and will follow precisely the slope of the wave. The movements of a flat board laid on the water are a practical illustration of this condition. The periodic time of such a board may be practically treated as = 0; and if a ship could be so constructed as to fulfil this condition, there might be some wisdom in attempting it. It is impossible, however, to construct a ship that will even approximately fulfil this condition, and as an approach to it could only be effected by giving her the greatest possible stability, she would only the oftener meet waves with which she would synchronise and experience the evil consequences of that condition.

One other critical case, the conditions for which are deducible from the equation of rolling motion, is that in which a vessel exposed to a series of waves performs her oscillations not in her own period but in that of the somewhat different wave period. In this case the still water oscillations would not synchronise with the wave period; but a relation subsists which enables the increasing slope of each wave to just counteract the growing inclination of the ship. At the wave hollow and crest a ship under such conditions would be upright: and she would reach her greatest inclination to the vertical when she was in an intermediate position upon the greatest slope of the wave. She would roll so that her masts would always lean towards the wave.

A general feature of the theory as deduced from the equation of rolling motion is that when the natural time of oscillation of a ship and the wave period do not synchronise, and when the rolling has not become permanent, the ship's oscillations will pass through phases analogous to the action of a pendulum when subjected to a series of impulses partially synchronous with its own excursions; and, as we have seen, this deduction is in accordance with the observed phenomena of rolling.

The results given by Mr. Froude's equation for unresisted rolling give, so far as character is concerned, a generally correct view of what actually occurs. But, quantitatively, the angles of oscillation indicated are

largely in excess of the truth. A most important practical circumstance is left entirely out of account in the equation, viz., the fact that the oscillations are performed in a resisting medium. The laws of resistance to rolling are not sufficiently well understood to enable their modifying effect to be introduced into a general equation, and a direct and theoretical solution of the question thus attempted. Mr. Froude has shown, however, how in the case of any individual ship an approximate solution may be obtained with certainty by help of data derived from a single experiment with the ship herself, or even with a carefully made model of her, tried in still water. He has also pointed out that if a well-selected series of such experiments were tried for ships of different forms, and the results tabulated, the series of corresponding solutions would enable him to determine, as if *à priori*, what modifications the results of his equation would require for any ship whatever.

The resistance which a ship experiences in oscillating through a given angle among waves is practically the same as it would be if she were performing an oscillation of the same range in still water. If she is set rolling in still water the resistance will rapidly bring her to rest when the force which caused her to roll ceases to act. In the same way, when rolling among waves, the same resistance will reduce the angles of oscillation. It is this circumstance which prevents dangerous angles being reached in the critical case of synchronism, and which, at all times, fixes the limiting position to which a ship will roll. The action of the waves in increasing the angle of roll is balanced by the opposing tendency of resistance to reduce it. The aggregate resistance of a ship to rolling is made up of three parts: (1) That due to the friction of the fluid in moving over the skin of the ship; (2) the direct resistance of the keel and fine parts at the ends to being pushed through the water at right angles, or nearly so, to their planes; and (3) what Mr. Froude calls the "wave-making function," or the element of resistance caused by the successive displacements of fluid in rolling which affect the surface as waves, and travel away from the ship, thus abstracting from her the energy they embody.

The aggregate resistance to rolling being of such a character, and containing elements which vary in different ways with the rate of motion of the surface of a ship's bottom, its exact computation in a particular case would be very difficult. Mr. Froude has, however, done much towards enabling a sufficiently close approximation to be arrived at by direct calculation. For practical purposes, however, Mr. Froude's original suggestion of determining the amount of resistance by still water experiments is employed. A ship is set rolling in still water, and upon reaching an angle of sufficient magnitude, she is allowed to come to rest under the action of resistance only. The rate of extinction of her range of oscillation is continuously noted and registered in the form of a curve. It will be obvious that the difference in amplitude of two successive swings measures the aggregate effect of the resistances operating upon the ship, and that by means of a complete curve of extinction a measure of the resistance opposed by her to rolling among waves may be obtained.

This is, necessarily, but a general description of Mr. Froude's theory, and does not include many details and some collateral matter which are of importance in making it quite complete; but it will serve to give an indication of its broad features.

Mr. Froude's theory has met with general acceptance as being a sufficiently close approximation to a correct expression of the laws of motion of a floating body among waves. Some of the departures from absolute accuracy contained in the assumptions necessary to the formation of the theory, such as that wave-water is continually changing its form, and a ship being a rigid body, cannot therefore, strictly speaking, be said to accept the dynamical conditions of the displaced fluid as it accepts the statical conditions of its still-water displacement; and the objection that a sub-surface of equal pressure does not correctly represent the effective wave surface have been criticised; but the criticisms have only shown that the errors thus involved are very small in amount and have no appreciable effect upon the general results of the theory. Mr. Froude has always insisted himself upon the existence of imperfections in his theory, but he has constantly been at work upon their removal, and upon the determination of the tangible amount of error they introduce into the ultimate result.

Mr. Froude's work was undertaken at first with a practical object, on account of Mr. Brunel's requirements, and it has already accomplished great practical results. It has led to the conclusion that ships of long periods are least likely to meet with waves which will cause them to roll heavily, and that the rolling of a ship can be greatly reduced by means of deep-bilge keels. These ideas have been extensively acted upon in H.M. Service. Our heavy armour-clads and other ships of war have been designed in accordance with this theory, so as to have great steadiness at sea, and in many special cases their properties have been determined by Mr. Froude beforehand, so that instead of working in the dark the Admiralty have known what behaviour to expect from a ship after she is built. The effect of bilge-keels in extinguishing rolling was clearly shown by Mr. Froude in 1871, with a model of the *Devastation*. Without bilge-keels the model performed 31½ complete oscillations before coming to rest in still water, after being inclined to an angle of 8½°, but with a bilge-keel equivalent to 36 inches in depth on the full scale of the ship, she came to rest in eight oscillations, and with a bilge keel double this depth she came to rest in four oscillations. The same model when tried among waves which capsized her when no bilge keels were fitted only rolled to an angle of 13½° with 3 feet bilge keels, and to 5° with 6 feet bilge keels. These experiments showed conclusively the effect of bilge keels in limiting the range of oscillation among waves.

The importance of bilge keels was further tested by comparative trials conducted by Mr. Froude off Plymouth in 1872 between H.M. ships *Greyhound* and *Perseus*—both of the same class—the former having bilge keels and the latter being without them. Mr. Froude also conducted an elaborate series of experiments on board the *Devastation* at sea in 1873 and 1875, and, by means of a most ingenious machine of his own construction, obtained continuous automatic records of her behaviour. These records showed (1) the relative inclination of the ship and the effective wave slope at any instant; (2) the inclination of the ship to the vertical at any instant; and (3) the period of oscillation of the ship at any time, that is, the number of seconds occupied in completing the roll from port to starboard, and *vice versâ*. From the diagrams upon which (1) and (2) are traced in the form of curves Mr. Froude deduced, as a differential result, the period and angle of slope of the effective wave surface at any instant, thus determining it with a much greater degree of exactness than that with which the form of a surface wave could be ascertained.

Mr. Froude was constantly checking and correcting his theoretical results by the aid of experiment, and though he had succeeded in fully establishing the true theory of the rolling of ships among waves, he did not rest satisfied with his success, but had recently made arrangements at his experimenting tank at Torquay for proceeding with further important lines of investigation by means of observations upon the behaviour of models in waves mechanically generated.

We have only dealt with Mr. Froude's labours in connection with the question of the rolling of ships in this number, and must reserve a description of his investigations into the laws of resistance and propulsion, which are at least of equal importance, for another occasion.

(*To be continued.*)

THE COLD WEATHER OF LAST WINTER AND SPRING

THE winter and spring just past will be historically memorable for the unprecedentedly cold weather which has been the outstanding characteristic. More intense cold has no doubt been experienced in former years for single nights, or for brief intervals of a few days, than has been recorded anywhere in these islands during the past six months; but for upwards of a century since thermometric observations of the temperature of the air began to be made in Great Britain there has not occurred, so far as these observations show, a tract of weather so cold, as respects duration and intensity combined, as has prevailed during the half year ending with May.

From January, 1764, we have a consecutive series of monthly mean temperatures before us from observations made on the south shores of the Moray Firth and of the Firth of Forth. From this unique and valuable record we give the following periods of protracted low temperatures extending over intervals of from five to ten months, which have occurred in North Britain during the past 115 years, the amount of the depression below the means of the months being at least three degrees:—

Date of Cold.	Duration in months.	Under mean temperature of the months.
		°
February–November, 1782	10	−5·1
January–August, 1799	7	−3·8
October–March, 1799–1800	6	−3·3
November-April, 1807–8	6	−3·5
March–August, 1812	6	−3·4
October–March, 1813–14	6	−3·6
November–August, 1815-16	10	−3·5
January–May, 1838	5	−4·2
January–May, 1855	5	−3·5
December-April, 1859–60	5	−3·0

Of these periods the most intense and, excepting that of 1815-16, the most protracted cold was that of 1782, when, during the ten months beginning with February, the temperature was 5°·1 under the mean of these months, the deficiency being 5°·4 for the five months from February to June, and 4°·8 from July to November. It may be noted that of these ten periods of protracted cold weather none occurred from 1764 to 1781; there were no fewer than seven during the next thirty-four years, and during the sixty-three years which have elapsed since 1816, only three such cold periods have been recorded.

Happily the extraordinary development and extension of meteorological observation which has taken place in late years enables us to define with some precision the distribution of the great cold of 1878–79 over the British Isles. For this purpose we have selected ninety-two places well distributed over the United Kingdom, and calculated their mean temperatures for the six months from December to May, and compared them with Buchan's mean temperatures and isothermals of the British Isles.

From the results thus obtained, it appears that this cold weather was felt in its greatest intensity in Central Enlgand, where, within a circuit roughly defined by a line passing near Stonyhurst, Shrewsbury, Cirencester, Oxford, Audley End, Yarmouth, Kelstern in Lincolnshire, and Durham, the depression of the temperature below the means of the six months exceeded 6°·0, falling to 6°·7 below the average at Cirencester and 7°·4 at Shrewsbury. Large portions of the south of Scotland between the Solway and the Firth of Forth and in Perthshire had also a mean temperature for the period fully 6°·0 under the average. Northwards through Central Scotland as far as Lairg in Sutherland, the depression of temperature was only about 5°·0 below the average; and this appears to have been about the deficiency experienced over central Ireland, falling, however, to 5°·7 at Armagh, and 5°·3 at Lissan, on the west of Loch Neagh. Everywhere round the coast the cold was less intense than in the interior. Temperatures were from a degree to a degree and a half relatively milder along the east coast, and still milder on the west coast; indeed, Shetland, Orkney, the Hebrides, the south of Ireland, Scilly, and the Channel Isles had a mean temperature only from 2°·0 to 3°·0 below the average temperature of the period, so greatly was the conserving influence of the ocean felt on the temperature of places in the west and south during this memorable cold weather.

During these six months, the greatest depression of temperature, absolutely as well as relatively to the monthly means, took place in December and January. If the monthly means be only looked at, the absolutely greatest temperature depression during the period was in December, in the counties of Cumberland and Dumfries, and along the upper reaches of the Tweed and Clyde, with their affluents. Within this region the mean temperature of December, reduced to sea-level, did not rise above 29°·0, falling at some places as low even as 27°·5. The week of intensest cold was the second week of December, when the mean temperature fell at many places in England, Scotland, and Ireland, to from 15°·0 to 18°·0 below the average of the season.

If we look at the monthly mean temperatures of the past 115 years as compared with their averages, with the view of ascertaining the duration of the most protracted periods of cold weather which have occurred during this long interval of years, defining as a period of cold weather an interval of time during which the mean temperatures of the months were continuously under their averages, we find that there have occurred four such noteworthy periods of protracted cold weather, during which the mean temperature of no month included in it rose above its average. These, arranged in the order of their duration, are (1) A period of 19 months, extending from September, 1798, to March, 1800, the mean temperature of this long period being 2°·8 below the average; (2) A period of 17 months from September, 1859, to January, 1861, which was 2°·2 below the average; (3) A period of 15 months, from October, 1815, to December, 1816, which was 3°·0 below the average; and (4) A period of 14 months, from February, 1782, to March, 1783, the mean temperature of which fell 4°·4 below the average of the months. It is thus only too evident that while the cold weather most of us have been suffering from these six months exceeds in intensity any other past period of cold weather in these islands of like duration of which we have an exact and authentic record, the temperature observations of the past 115 years disclose to us tracts of unseasonably cold weather, two or even three times more protracted than the interval which has yet elapsed since the present cold set in with such intensity and persistence in November last.

THE ICE CAVERN OF DOBSCHAU[1]

WHILE on a tour in Hungary last summer I had the opportunity of visiting an ice cavern near the town of Dobschau; the discoverer of the cavern kindly conducted me through it and wished me to make it known to the English public; with this object in view I have written the following short account:—

The cavern is situated to the north-west of Dobschau, and is approached through a narrow winding limestone valley, "the Stracenaer Thal." It has a general direction from west to east in the interior of a mountain whose slope faces north; the descent into it varies from oblique to precipitous, the entrance, which is very narrow, being situated at the highest point of the cavern; the ice consists of innumerable layers frozen together one upon the

[1] Dobschau is situated a little to the south of the Kaschau-Oderberger-Bahn, the nearest station on that line being Iglo.

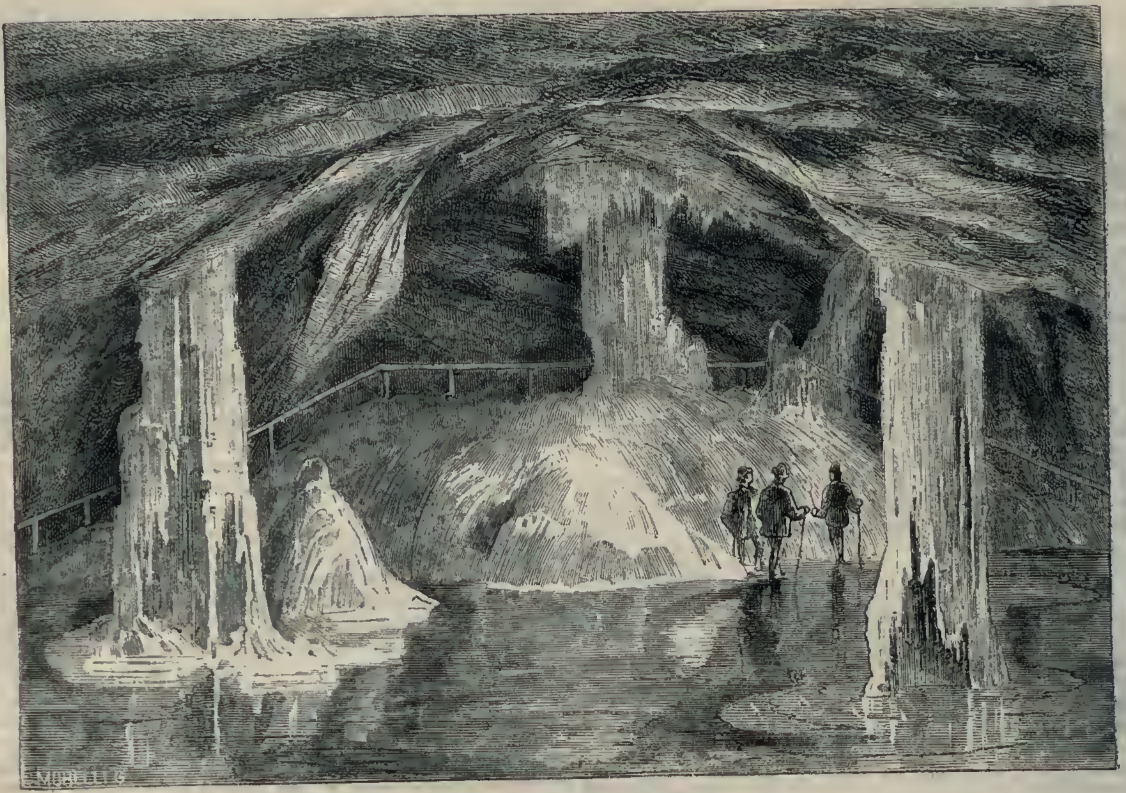

Fig. 1.—Portion of the Great Saloon.

Fig. 2.—The Corridor.

other, and assuming various fantastic shapes. The total surface of ice and rock is 8,874 square metres, that of the former being 7,171 square metres, of the latter 1,703 square metres; the mass of the ice amounts to 125,000 cubic metres.

The cavern consists of two parts, an upper and lower stage; the former is reached immediately after leaving the entrance, its floor being formed of ice, its roof and walls of limestone; it is partially divided into two unequal chambers, the small and great saloons (Fig. 1), by a curtain of rock descending from the roof. The small saloon is not situated on the same level as the great saloon. In the great saloon are three ice pillars (Fig. 1); they are translucent, and down the cylindrical hollow of one pillar there is a continuous though small flow of water; in addition there are numerous other ice ornaments which have received fanciful names. The eastern end of the saloon is contracted into a very narrow corner; at this point there has been a landslip corresponding to a crater-shaped depression in the slope of the Duosa Mountain, in which the cavern is situated. In the small saloon to the right of the entrance is a waterfall composed entirely of ice.

The lower stage consists of a corridor (Fig. 2) following the south side wall of the saloon; the downward prolongation of the dome-shaped rock wall of the saloon forms the south corridor wall, while the naturally formed cross-section of the ice constitutes the northern. The corridor originally consisted of two portions, a right and left wing, separated by a mass of ice; this has now been bored through. The entire length of the corridor is 200 metres.

The right corridor wing is reached from the small saloon by going down a steep flight of steps through a natural opening; the mass of ice whose upper surface forms the floor of the saloon after touching the roof suddenly terminates so as to make a nearly vertical wall to the corridor; the floor of the latter sinks down into the depths below, terminating in a mass of *débris*; this point probably forms a natural outlet for the water.

In the left corridor-wing is a magnificent ice structure termed the Grotto (Fig. 3).

The cooling of the air and the permanent low temperature (the mean of the year being $-\cdot86°$ C.) of the cavern are due to its height and northern aspect, as well as to its narrow opening and contracted exit canal, and to its floor gradually sloping inwards; as a result of this, the water is converted into ice, and the permanence of the latter thus insured.

Through the kindness of Herr Ruffiny, the discoverer, and Dr. Pelech, I have been enabled to obtain the loan of the woodcuts.

W. BEZANT LOWE

FIG. 3.—The Grotto.

THE VISITATION OF THE ROYAL OBSERVATORY

ON Saturday last the annual visitation of the Royal Observatory was held, when the Astronomer-Royal read his annual report, which refers to a period of thirteen lunations, from the new moon of 1878, May 2, to the new moon of 1879, May 20. We notice some of the most important points in this report:—

Considerable alterations have been made in the great equatorial, so as to make the instrument easy for use with the long half-prism spectroscope. The declination axis being meridionally excentric by 14 inches as regards the polar axis, the observing-chair may be made available for eye-observations and for spectroscopic observations respectively, by reversing the instrument in hour-angle so as to take advantage of this excentricity.

With regard to the numerous group of minor planets, the Berlin authorities have most kindly given attention to the Astronomer-Royal's representation, and we have now a most admirable and comprehensive ephemeris.

The meridian observations of stars are directed primarily to the determination, with the greatest attainable accuracy, of the places of 215 fundamental stars observed throughout the day and night, and these are supplemented by observations of stars taken from a working catalogue of about 2,500 stars. About 1,300 of these stars were observed in 1878, forming a larger annual catalogue than usual.

As might have been expected, the Astronomer-Royal's report on the weather of the past year is not satisfactory. After a fine autumn, the weather in the past winter and spring has been remarkably bad. More than an entire lunation was lost with the transit-circle, no observation of the moon on the meridian having been possible between January 8 and March 1, a period of more than seven weeks. Neither sun nor stars were visible for eleven days, during which period the clock-times were carried on entirely by the preceding rate of the clock. The accumulated error at the end of this time did not exceed 0s.·3.

"During the past year, spectroscopic observations have been almost entirely suspended, in order that the reductions of accumulated photographic observations might proceed more rapidly. The sun's chromosphere has been examined on seven days only, and, on five of these, prominences were seen. Two measures of the displacement of the F-line in the spectrum of α Virginis, and 26 of the *b* lines in the spectra of 6 stars (3 of them not previously examined), as compared with the corresponding lines of hydrogen and magnesium, have been made. In five of these, though the stars were of the second magnitude only, a dispersive power equivalent to fifteen prisms of 60° was used. These observations were checked by reference to the F or *b* lines in the spectrum of the moon or of the sky. The spectrum of Brorsen's comet has been examined with the half-prism spectroscope, and that of the eclipsed moon on 1868, August 12, with the single-prism spectroscope.

"Photographs of the sun have been taken on 150 days, and 228 of these have been selected for preservation. The photographs show a complete absence of spots on 121 days out of 150; and on comparing them with those of the preceding year, when there was an absence of spots on 66 days out of 156, it appears that we have not yet passed the minimum.

"The following are the principal results for magnetic elements in the year 1878:—

Approximate mean westerly declination	18° 49′.
Mean horizontal force ...	3·905 (in English units). 1·801 (in Metric units).
Mean dip	67° 37′ 10″ (by 9-inch needles). 67 38 12 (by 6-inch needles). 67 38 59 (by 3-inch needles).

"The magnetic reductions for the years 1865 to 1876 are nearly completed. The results are exhibited in the form of annual and monthly mean curves of diurnal inequality, as in preceding investigations, the abscissæ showing the variation of magnetic declination, and the ordinates that of horizontal force, throughout the twenty-four hours. The annual curves of diurnal inequality are now complete for the period of thirty-six years, from 1841 to 1876; and from the great length of this series of observations," the Astronomer-Royal goes on to say, "all made on the same system and with similar instruments, most important inferences may be drawn, both as to the laws of diurnal inequality in general and its changes in different years and seasons, and as to the connection between magnetic phenomena and sun-spots. These annual curves show a well-marked change in close correspondence with the number of sun-spots. About the epoch of maximum of sun-spots they are large and nearly circular, having the same character as the curves for the summer months; whilst about the time of sun-spot minimum they are small and lemniscate-shaped, with a striking resemblance to the curves for the winter months. We think with the Astronomer-Royal that it may be worthy the consideration of the Board whether the whole of these results, with any modifications that experience suggests, should not be printed and circulated as a separate volume.

"The monthly curves, 1865-76, have been formed for three periods of four years each, corresponding roughly to periods of minimum, maximum, and mean of sun-spots, and the whole series stands thus (the general character of the curves being added):—1841-47 (curves) mean; 1848-57, small; 1858-63, large in summer, small in winter; 1865-68, small; 1869-72, very large; 1873-76, mean. The maxima of sun-spots occurred in 1848, 1860, and 1870, and the minima in 1844, 1856, and probably in 1879.

"The connection between changes of terrestrial magnetism and sun-spots," the Astronomer-Royal states, 'is shown in a still more striking manner by a comparison which Mr. Ellis has made between the monthly means of the diurnal range of declination and horizontal force, and Dr. R. Wolf's "relative numbers" for frequency of sun-spots. It appears from this that not only is there a general correspondence in the two sets of phenomena, but that the minor irregularities of the sun-spot curve are reproduced in the curves of diurnal magnetic range; and further that the well-marked annual inequality in the latter is itself variable, being greatest at the time of maximum of sun-spots and least at that of minimum. It will be an interesting inquiry, when sun-spots become more numerous, to determine whether the present paucity of earth-currents is connected with the fewness of spots."

The Astronomer-Royal, by these researches, has endorsed the work we owe to Sabine, Broun, Stewart, and others.

The Report states that the Westminster clock has not been quite so well regulated as usual. During the period to which this Report refers, its error exceeded 1s. on 77 days; on 15 of these it was between 2s. and 3s., on 4 between 3s. and 4s., and on 1 day it exceeded 4s.

With regard to the last Transit of Venus results, the past year has been occupied in putting reports and calculations in a shape adapted to eventual printing of the account of the whole enterprise. With regard to the Transit of 1882, the Astronomer-Royal informs us that the general impression appears to be that it will be best to confine observations to simple telescopic observations or mcirometer observations at ingress and egress, if possible at places whose longitudes are known. For the first phenomenon (accelerated ingress) the choice of stations is not good; but for the other phenomena (retarded ingress, accelerated egress, retarded egress), there appears to be no difficulty. The adoption of a south-polar station seems to be practically abandoned.

With regard to the numerical lunar theory, the Report states that the incessant pressure of the business of the observatory has prevented the Astronomer-Royal advancing so rapidly as he had hoped. "The solar perturbing forces are all computed to 10^{-7} in all cases, and to 10^{-8} and 10^{-9} in those cases in which large factors are introduced by theory as necessary for obtaining the correction to tabular coefficients from discordance of computed deductions (lunar places on one side, with solar forces on the other). The lunar places with the same arguments, first computed to 10^{-7}, are now extended to 10^{-8} or 10^{-9}, for the powers of radius vector. The computations of the same kind for the other assumed elements (longitude and latitude) are not begun. In regard to the discordance of annual equation, to which I called attention in the last Report, I suspend my judgment. I have now discussed the theory completely; and, in going into details of secular changes, I am at this time engaged on that which is the foundation of all, namely, the change of

excentricity of the solar orbit, and its result in producing lunar acceleration."

With reference to the practicability of reducing the extent of the printed volume of "Greenwich Observations," the report concludes with some of the suggestions that have been made by certain members of the Board. The introduction, it has been suggested, might to some extent be stereotyped. No reduction, it is thought, should be made, in regard to the details of meridional and altazimuth observations.

To the strong appeal made for extension of the spectroscopic observation of stars, in reference to their motion in the line of sight, the Astronomer-Royal has given a tacit response by the modification of the S. E. Equatorial, so as to facilitate that extension. "The tendency of external scientific movement," he remarks, "is to give great attention to the phenomena of the solar disk (in which this observatory ought undoubtedly to bear its part). And I personally am most unwilling to recede from the existing course of magnetical and meteorological observations. All these, however, are inferior in importance, with regard to the question now before us, to the extent of printing the original details of astronomical observations."

"The general tendency of these considerations is," the report concludes, "to increase the annual expenses of the Observatory. And so it has been, almost continuously, for the last forty-two years. The annual ordinary expenses are now between two and a half and three times as great as in my first years at the Royal Observatory. I would fain flatter myself that the value of its results has increased in a greater degree."

NATURAL SCIENCE DEGREES AT OXFORD

DR. ODLING, replying in the *Times* to Canon Liddon's letter, referred to in NATURE, vol. xx. p. 132, maintains that unless some little Greek is considered absolutely essential to a liberal education, there can be no ground for refusing a degree in arts to students who, though unacquainted with Greek, are familiar with such like studies as geometry, arithmetic, and astronomy, which equally with grammar, dialectics, and rhetoric, have been counted from time immemorial among the liberal arts. And assuming the compulsory modicum of Greek now brought up by mathematical and natural science students to be a non-essential element of their liberal education, as certified to by a degree in arts, how can a degree in arts be hereafter refused to advanced students of either of these subjects who, while still bringing up Latin, shall in future offer a considerable amount of German, together with some amount of both mathematics and natural science as a substitute for the present modicum of Greek?

Dr. Odling, rather than degrade science by awarding its graduates an inferior degree, seems disposed to retain the little modicum of Greek at present required for a pass; he would have been contented with Canon Liddon if the existing arrangements had been undisturbed. His objection is not to the incubus of Greek, but to the slur about to be put on natural science.

Canon Liddon replies that, in speaking of the educational advantages of Greek, he was in part thinking of the *minimum*. He believes Dr. Odling mistaken in thinking that the new degree was intended as anything but an honourable distinction. No one could suppose, he believes, that the majority of the present Council could be unfriendly to physical science. The statute appeared to him to be drawn almost exclusively in the interests of natural science students, and with a view to relieving them of an uncongenial study.

In a subsequent letter Dr. Odling quotes a passage from a lecture delivered by Dr. Whewell some twenty-five years ago. In the course of showing that the great contributions made to intellectual education by Greece, Rome, and modern Europe in succession have been geometry, jurisprudence, and physical science respectively, he wrote as follows:—

"Our intellectual education now, to be worthy of the time, ought to include in its compass elements contributed to it by every one of the great epochs of mental energy which the world has seen. . . . A mind well disciplined in elementary geometry and in general jurisprudence would be as well prepared as mere discipline can make a mind for most trains of human speculation and reasoning. . . . But however perfectly the habits of deduction may be taught by these studies, such teaching cannot, according to the enlarged views of modern times, compose a complete intellectual culture. . . . As the best sciences which the ancient world framed supplied the best elements of intellectual education up to modern times, so the grand step by which, in modern times, science has sprung up into a magnitude and majesty far superior to her ancient dimensions should exercise its influence upon modern education, and contribute its proper result to modern intellectual culture."

Happily the further discussion has been postponed until Michaelmas Term; by that time it is hoped that some method will be found by which natural science will be honoured without hurting the feelings of any one. We may state that the Council of the Cambridge Senate recommend to the Commissioners that power be given in the statute to recommend degrees in science (B.Sc., M.Sc., D.Sc.).

ON SOME MARINE ALGÆ[1]

THE successor of Harvey in the Chair of Botany in the University of Dublin has taken, as his eminent predecessor did, the algæ for the principal object of his study. In 1877 Dr. E. P. Wright published in the *Transactions* (vol. xxvi. Science) of the Royal Irish Academy two memoirs, one on a green unicellular alga (*Chlorochytrium Cohnii*) parasitic in the mucous tubes of some diatoms, in *Polysiphonia urceolata*, and in *Calothrix confervicola*; the other on a parasite deprived of chlorophyll (*Rhizophydium Dicksonii*), which develops itself in the cells of an Ectocarpus, and which has been taken, at least in one case (*E. crinitus*, Harv.), for the fruit of an Ectocarpus. This present year the *Transactions* of the same Academy contain two additional memoirs by the same author, which are accompanied by three coloured plates drawn by Tuffen West. The latter memoirs seem to me to be conceived in a spirit, and executed after a manner, which one does not always meet with in the writings of the British algologists. Dr. Wright has studied the living plants, an innovation on which he cannot be too much congratulated. One would only wish that his exact and minute observations on the development of organs, a subject in which he has shown himself at home, had been joined to an experimental determination of their functions, a determination which morphology by itself is powerless to declare to us. It is easy to prove this latter statement by a few instances taken from authors whose abilities have been placed beyond all doubt. Thus it has been said over and over again—Naegeli himself believes it ("Algensysteme," p. 134, Pl. 1, Fig. 34; 6)—that the heterocysts of the Nostocs are reproductive bodies, while experiments the most easily made prove that they are nothing of the sort. Cramer ("Phys. syst. Untersuch. über die Ceramieen," Heft 1, p. 125) has mistaken the antheridia of Bonnemaisonia for young cystocarps. Dr. Wright has, as we will show further on, been himself the victim of a similar error. Morphology is not like the spear of Achilles; it does not heal the wounds which it makes.

Griffithsia setacea is a pretty, red alga, well known to

[1] From the French of Ed. Bornet.

all collectors of marine plants. It is composed of branched filaments made up of large cylindrical cells placed end to end in a single row. When it is in fruit, the filaments are furnished with short branches terminated by a globular involucre, in the interior of which are ranged the reproductive bodies. How are these formed, and how do these filaments and appendages grow? What modifications do the cell-contents experience during this formation and growth? These are the points explained with a good deal of clearness by Dr. Wright in the first of the two latter memoirs referred to (on the cell-structure of *G. setacea*, and on the development of its antheridia and tetraspores). Referring to the memoir itself for details, I would only call attention to a peculiarity noticed in the development of the involucre. The rays which compose it take their origin in a circle from the penultimate cells of particular ramuli, formed by a small number of cells and slightly club-shaped at their superior extremity. These rays are not all at once free. Detached from the protoplasmic mass on which the apical cell reposes, they for a long time increase underneath the common membrane which clothes the frond, and they are only made free somewhat later on by the rupture of this membrane. First of all figured, but very imperfectly by Derbes and Solier, well represented from life by Thuret, this peculiar disposition is shown by Dr. Wright as made clear by the use of reagents, and it would appear to be equally met with in the genus Pandorea, recently described by J. Agardh.

In following from their first appearance the development of the reproductive organs on the rays of the involucre, Dr. Wright observed that the cells destined by their origin and their position to form the tetraspores, did not all comport themselves in the same manner. Some of them produced the ordinary four spores, but in the interior of the others globular cells arose provided with a beak, from which there came out colourless corpuscles, wonderfully like the antherozoids of the Florideæ. The resemblance of these bodies to species of Olpidium did not escape Dr. Wright, but struck by their constant presence on the specimens which he examined, by the regularity with which they appeared on determined points of the involucre, he thought they might be regarded as the antheridia of *Griffithsia setacea*, and here he has overlooked the fact that true antheridia, of the ordinary type in the Florideæ, had long since been described and figured in this very species by Thuret (*Ann. des Sc. Nat.* 3 ser. Bot. Tom. 16). On this occasion Dr. Wright, however, records an observation as new as interesting, viz., that he has seen the corpuscles as they left these wrongly imagined antheridia perform movements after the manner of amœbæ.

In the second of the two memoirs, having for its title "On the Formation of the so-called 'Siphons,' and on the Development of the Tetraspores in Polysiphonia," the author describes with much care the method of the formation of the frond in *Polysiphonia urceolata*, and very exactly proves the relationship existing between the "tube central" and the "siphons," and between the siphons themselves. For a great part he therein only confirms the results of those preceding him in such investigations, for the history of the development of the frond in Polysiphonia has been almost exhausted by the works of Naegeli, Kny, and Magnus. I am almost afraid that an analysis of these minute details would inspire the reader with that horror which, according to Naegeli, such morphological researches bring with them to the systematic botanists, but I cannot bring myself to omit extracting the following passage, in which some curious vital phenomena are incidentally described by Dr. Wright, as he found them to exist in the cells of Bryopsis.

"Under the influence of some local irritation, which must not be enough to injure the cell wall of the specimen under examination, the denser portion of the protoplasm will often be found to draw itself from the upper part of these cells. As it does so, the very conspicuous chlorophyll granules will be seen to be drawn together until they become pretty tightly packed. There is an apparent rounding off of the upper portion as it gets drawn down in the tube of the cell wall, and under a low power of the microscope this convex surface seems pretty sharply defined; but turn on a high quarter of an inch or an eighth of an inch objective, and a very remarkable phenomenon will present itself—for there will then be seen a mass of pseudopods not easily to be forgotten and difficult to describe under any other name; they stream away from below the apex of the cell wall, converging downwards until they are lost in the centre of the convex margin of the withdrawing mass of protoplasm. Here they are broad, while towards the apex of the cell they disappear through their very tenuity. Coursing down along these pseudopods, very minute granules can be, on careful focussing, detected; these are ultimately lost in the denser protoplasmic mass which engulphs them. This streaming goes on for a while, until all the protoplasm of a certain density is drawn into the lower mass; this then finally rounds itself off and forms an independent cell wall in front, which of course will be below the former growing point of the cell. There is apparently no plastic protoplasm remaining above this—no small disc even of homogeneous mucilage to be seen; all the viscid protoplasm seems to have gone to the rear, and it would appear as if the upper portion should now become sphacelated—perhaps disappear—and a new apical growth proceed from below it; but this is not so; there is life in the front still; it goes on growing as before, and in process of time it will be found to leave in its rear dense chlorophyll-bearing protoplasm, and so on through the several layers until the *punctum* itself is, as before, reached."

OUR ASTRONOMICAL COLUMN

BIELA'S COMET.—As bearing upon the possible return of Biela's comet during the latter part of the present year, it will not be out of place if we here summarise the results of an investigation made by Prof. Oppolzer in 1873, on the possible connection of the comet discovered by Mr. Pogson at Madras on December 2 previous, with Biela's comet and the great meteoric shower of November 27, 1872. It will be remembered that the comet in question was found in consequence of a telegram sent by Prof. Klinkerfues to Madras immediately after the meteoric display, to the effect that Biela's comet had "touched the earth" on the evening of November 27, and urging Mr. Pogson to search for it near the star θ Centauri. From the Madras observations on the nights of December 2 and 3 (the only occasions on which the weather was favourable), as they were first approximately reduced, Oppolzer derived the following data:—

1872, December 3·0 M.T. at Berlin.

Comet's geocentric longitude (λ)	... ...	223 15′·6
,, ,, latitude (β)	... ...	− 20 10·0

And the unit of time being a mean solar day,

$$\frac{d\lambda}{dt} = + 187'\cdot 0, \ \frac{d\beta}{dt} = + 46'\cdot 3.$$

At a subsequent time Mr. Pogson published more accurate positions of the comet than those at first communicated, which would give the following similar data, differing, it will be seen, in no material degree from those adopted by Oppolzer:—

1873, December 3·0 M.T. at Greenwich.

$$\lambda \ldots 223^\circ\ 21'\cdot 1 \quad \beta \ldots -20^\circ\ 8'\cdot 6 \quad \frac{d\lambda}{dt} \ldots + 189'\cdot 9 \quad \frac{d\beta}{dt} \ldots + 46'\cdot 4$$

It had soon been found, as might have been expected, that no satisfactory conclusion could be arrived at by comparison of Michez's elements of Biela's comet with

the observations, proportionally small variations in the elements producing greatly magnified effects upon the geocentric place and geocentric motion, in consequence of the close proximity of the comet.

Oppolzer describes his method of calculation in No. 1,938 of the *Astronomische Nachrichten*, to which we must refer the reader, as an outline of it would unnecessarily extend this note. He makes three assumptions as to the distance of the comet from the earth and deduces three orbits for comparison with the orbit of Biela's comet, as follow :—

	(A)	(B)	(C)	Orbit of Biela.
Distance assumed ...	0·04	0·08	0·12	—
	° ′	° ′	° ′	° ′
Mean anomaly	− 4 54·4	− 5 6·8	− 5 4·8	—
Long. of perihelion ...	128 48	141 9	151 50	109 45
,, ascending node	247 38	244 34	242 12	245 50
Inclination	9 14	10 28	11 46	12 22
Angle of excentricity..	51 36	54 17	56 49	48 48

It must be added that Oppolzer pre-supposes the comet moving in an orbit with same semi-axis major as that of Biela, the corresponding mean daily motion being 530″·1; hence with the above mean anomalies on December 3·0, the dates of perihelion passage on the three hypotheses would be respectively January 5·3, January 6·7, and January 6·5.

The similarity of these systems of elements is striking; only in the longitude of perihelion are there comparatively large differences, which Oppolzer observes, may not appear so noteworthy when it is remembered that Michez's elements do not include the effect of perturbations from 1866 to 1872, nor those which might just have resulted from the presumed exceedingly close approach of the comet to the earth on the night of the meteoric shower. The great difference of nearly three months in the perihelion passage, however, he regarded as against the identity of the object with Biela's comet, though from the anomalies which the disintegration of the comet might have occasioned, this circumstance might not really possess all its apparent signification. His general conclusions may be stated thus :—It may be asserted with confidence that assuming the distance of Pogson's comet from the earth December 3·0 to have been within the limits 0·04 and 0·12 of the earth's mean distance from the sun, we are led to elements which show a remarkable resemblance to those of Biela's comet, as well as with the course of the great shower of meteors on November 27, 1872. When the distance is much increased we find materially different elements, and the greater distance cannot be regarded as improbable; in this, Oppolzer remarks, lies in his opinion the weakest point of the argument, and only by observations at a future time can a certain conclusion be attained. Nevertheless he considers the striking coincidences following on arbitrary assumptions, taken together, militate strongly in favour of the approximate correctness of his assigned distance. Thus there seems to be under the above suppositions as to the comet's distance, a most remarkable connection with the meteor-shower of November 27. If, as a rough approximation, it is assumed that the comet at 8 P.M. on that day touched the earth, and further, that the differential daily variation of the distance within the $5\frac{6}{8}$ days was equable, an hypothesis, which in the case of a contact, will not differ much from the truth, there will be deduced from the three values, for the distance of the comet on December 3, respectively 0·061, 0·071, and 0·080; comparing these values with those assumed, it is seen at once that an agreement is established with the final value, when the distance = 0·07 nearly. This result Oppolzer urges as highly deserving of note, and in his opinion almost demonstrates the connection of the swarm of meteors with the comet. On the supposition that the true values of the elements must be sought between the systems (A) and (B), considering further that the earth on November 7·3 was in 65°·9, heliocentric longitude, and that the comet if it gave occasion to the meteor-shower must have been situate near its descending node, so the longitude of the node by this criterion would be 245°·9, a value which also falls between the limits (A) and (B).

Further, if the distance of the comet from the earth is calculated from the above elements for the time of the meteor-shower, the following series is formed :—

A		B		C
0·024	... ...	0·009	... ...	0·053

and it is seen that the assumption of 0·07 for the distance on December 3, leads to a very close approximation of the comet to the earth at the time of the shower. Calculating now the comet's radius-vector for November 27·3, the three systems give logarithmically—

A		B		C
0·0042	... ...	9·9950	... ...	9·9908

while the log. distance of the earth is 9·9940. Consequently with elements A and B the comet is a little outside the earth's orbit, and with elements C it would occupy a position within it. At the first glance it will appear probable that necessarily the last relation must have place, or the comet would certainly have been detected ere it reached its least distance from our globe. On the one side, from the uncertainty of the data for calculation, the results may be considerably in error, on the other there may be some probability that the comet was visible in the southern hemisphere, and we might have received intimation that a comet of great brightness and with rapid motion was there recognised. Calculating from the three systems of elements the geocentric place, there result—

	A		B		C
λ	67°	... ...	110°	... ...	180°
β	+11	... ...	− 75	... ...	− 25

so that, in fact, with the system B, which appears to approach nearest the truth, the circumstances of visibility for the southern hemisphere would be favourable.

Weighing all these circumstances, Oppolzer thought it must be granted that Pogson's comet stands with high probability in intimate relation with the meteor-shower of November 27, and that it is possible the observed object was one of the heads of Biela. That the second head was not found, is not decisive against this, since the same, on account of close proximity to the earth, might have been situate in an entirely different quarter of the heavens, and besides, from its greater relative distance, might have been considerably fainter, so as easily to escape detection. Thus, at the time of writing his paper on the subject, Oppolzer was of opinion that the connection of Biela's comet with Pogson's object and the meteor-shower was by no means to be regarded as improbable.

GEOGRAPHICAL NOTES

THE *Golos* publishes a telegram, dated the 13th of May, from the celebrated Central Asian traveller, M. Prjevalsky, formerly a colonel in the Russian army. At that time he was on the river Buluguna. He had marched 600 versts from Saisan along the river Urumtsu, and would immediately set out for Chemi through the southern Altai mountains. All the members of his expedition were in good health.

THE Alexandria correspondent of the *Daily News* sends some details of Major Serpa Pinto's recent journey across Africa from Benguela to Durban. He tells us little that has not been already made known, and we shall look with eagerness for Pinto's promised work. Science has evidently had considerable attentiont rom Major Pinto during his journey. He has brought home a collection of 1,800 plants and "a superb collection of birds and insects." Astronomical and meteorological observations have been taken along the route, and several volumes of notes made, with maps. The Coandó, which flows into the Zambesi,

is stated to have a length of 600 miles. It says much for the enthusiasm, if not for the knowledge, of the *Daily News* correspondent that he places Major Pinto in the "first rank of African explorers."

THE International African Association have received letters from MM. Cambier and Dutrieux down to March 16. They state their intention of remaining at Tabora till the end of the *masika*, or rainy season, which commonly ceases at the beginning of May. M. Cambier says that he has established friendly relations with the Arabs, and that he has ample resources for the next year without further supplies being sent. He also advises having forwarded an entomological collection made by Dr. Dutrieux. Though intelligence respecting this unfortunate expedition is remarkably vague, it may be hoped that we shall before long hear of their having done some real work, as they are now well advanced into the interior, have ample supplies, and the proper travelling season before them. The Association's second expedition will probably not be long before they start for the interior, as MM. Popelin and Van den Heuvel were to arrive on May 29 at Zanzibar, whither they have been preceded by M. Dutalis, who has already been engaged in a preliminary examination of the River Wami.

M. DE VILLIERS, the new Governor-General of French Cochin China, was Director of the Interior in Algiers under General Chanzy. He is the author of a dictionary of all the Algerian tribes and sub-divisions of tribes. This valuable work was published some years ago at the expense of the French Government.

THE current number of *Les Missions Catholiques* contains an account by Père Schmitt of a journey to Loango, in Western Africa.

THE new number of the *Annales de l'Extrême Orient* contains the first instalment of Dr. J. Harmand's "Notes de Voyage en Indo-Chine," illustrated by a map and copies of Khmer inscriptions. This is followed by part of a paper on New Guinea, in which is embodied much information respecting the Karons, the Kebars, and the Amberbaks. There are also some remarks by R. Friederich on the archæology and iconography of Java.

THE ERUPTION OF ETNA

ON the night of Sunday, May 25, loud bellowings were heard by the dwellers on the northern slopes of Etna. Towards the morning of the 26th these increased, and about midday a dense cloud of smoke was seen to issue from the side of the mountain below the great crater, apparently half way between Randazzo and Linguaglossa. This cloud increased, and on the 27th the mountain was rendered invisible, and an effect like that of an eclipse resulted. A rain of fine black ash, "like powdered emery," fell for miles around, and was so thick that Capo di Schiso could not be seen from Taormina, a distance of two miles. This black rain continued all day, accompanied by thundering noises from the mountain. No exact information could be procured concerning the position of the centre of disturbance, because no one could approach the new craters. During the night of the 27th the ashes continued to fall, and "huge fires could be seen looming through the black clouds"—no doubt the reflection of the molten lava on the smoke above it. It was reported in Piedemonte, a village on the north-

east flanks of Etna, that three craters about a mile apart had opened at the points of a triangle, about six miles above Passo Pisciaro, a posting station nearly midway between Randazzo and Linguaglossa. Lava was said to be flowing in a valley to the north of the Val del Bove. On the 28th a great stream of lava was seen from Taormina to be descending the mountain in the direction of Randazzo, "while from the new craters great balls of fire were thrown high in the air, and burst into showers of fire like gigantic rockets, accompanied by thundering explosions." On May 29 the lava was still flowing, but the shower of ash was diminished. The facts, as above stated, were witnessed by an Englishman living in Taormina, 800 feet above the sea, at the north-eastern termination of the flanks of Etna, about fifteen geographical miles from the new craters.

Daily bulletins in the newspapers have given us the history of the eruption since May 29. It is to be regretted that these have not been more concordant. Many times has the lava stream reached the bed of the river Alcantara, according to the telegrams, and often the next day has it been a kilometre distance. A telegram from Rome dated

June 3, and published in the *Times* for June 4, asserted that "the lava has still half a metre to run before reaching the Alcantara." The previous telegram asserted that the lava had run eleven kilometres from the craters, had rolled into the Alcantara, and had obliterated the Commune of Mojo; while the telegram of the following day made the stream 350 yards from the Alcantara. The fact is, that part of Etna is not thickly populated; distances are often guessed at; the new craters are not easily reached; and the shower of ashes prevented accurate observation, hence the discrepancies. But by a careful comparison of the telegrams, with the *Dettagli sull' eruzione dell' Etna*, issued by the Prefect of Catania at frequent intervals, the broadside sheets entitled *Guasti dell' eruzione dell' Etna*, and the letter written, on May 29, from Taormina, to the *Times*:—by comparing these with the fine map (scale = 1·266 inch to the mile) of the Italian Stato Maggiore, some of the discrepancies disappear, and a just estimate may be formed of the position of the new craters.

All accounts agree in placing the new craters near Monte Nero, but unfortunately there are two minor cones near together which bear the name of Monte Nero. We are helped out of this difficulty, however by the statement that the new craters are 1,900 metres (6,232 feet) above the level of the sea, that the higher of the two Monte Neros is far above this level, while the lower of the two has a little to the west of it a space marked by contours 1,900 metres. Here, accordingly, we shall place the new craters without hesitation.

The great crater, Randazzo, and Linguaglossa, form the three points of a nearly equilateral triangle, within which at present the eruption is completely confined. Linguaglossa is 12 miles from Randazzo, and 11 from the great crater, while Randazzo is only 10 miles from the crater. The new craters are 5 miles from the great crater, 7¼ from Randazzo, 7 from Linguaglossa, 7 from Mojo, 6½ from the River Alcantara, and 5 from Passa Pisciaro.

The lava has devastated the wood of Collebasso, and has crossed the main road at Passo Pisciaro, destroying the bridge there. Several vineyards have been destroyed, and if the bed of the Alcantara is invaded, the water supply will be cut off from a large tract of fertile land. The lava stream at Passo Pisciaro is about half a mile broad and 100 feet in depth. On May 30 it flowed at a rate of one metre per minute.

The last bulletin received to-day (June 6) from Catania dated June 1, 10 A.M., ends as follows:—"L'eruzione continua al solito. La lava verso il fiume dilatasi sempre, e scende insensibilmente. Stanotte un nuovo braccio investi la vigna di Salvatore Cimino, che quasi distrusse, producendo un danno di circa trentamila lire. La casina prospiciente sullo stradale versa in imminento pericolo." Signor Silvestri of Catania, together with two Germans, have penetrated as near as possible to the new craters. Silvestri, together with Prof. Blaserna of Rome, and Prof. Gemellaro of Padua, have been appointed to report on the eruption, in the interests of vulcanology. It was asserted in the telegram of June 6 from Messina that the stream of lava is only 100 metres from the Alcantara, and that it is advancing at a rate of fifteen metres per hour. Loud rumblings and dense smoke proceed from the new craters.

During the last few days the telegrams have stated that the eruption is diminishing, and that although the lava has slowly progressed, it has not yet reached the Alcantara. Some curious errors have been propagated in the newspapers. Thus the *Times* correspondent in Naples, writing under the date of June 2 (published June 10), asserts that "the side on the north-west is rent in two, and the fiery mass is ejected to the height of 1,900 metres, or considerably more than a mile." The real facts are that the new craters stand at an elevation of 1,900 metres above the sea; while a fissure which does not extend over even one-half the north-west side of the mountain, has been formed near Monte Nero. It has been asserted that saline mud has recently been ejected; also that the craters emitted on June 2, 450 cubic metres of lava per minute; also that the principal lava stream has a front of 800 metres, and that it has flowed for six or seven miles, But in regard to any exact statements, it will be preferable to wait for the report of Professors Blaserna, Gemellaro, and Silvestri; or at least for the very detailed account of the eruption, which is sure to appear in the next number of Prof. de Rossi's *Bolletino del Vulcanismo Italiano.* G. F. RODWELL

NOTES

WE understand that by permission of the Statistical Committee of the India Office, the new tide-predicter, which has been constructed for the Survey Department by Mr. E. Roberts (*Nautical Almanac* Office), will be exhibited at the closing meeting of the Royal Society on the 19th inst. The instrument, although not yet out of the makers' hands, is sufficiently complete to show its entire working; in fact, the tide-curves for the year 1880 for Bombay and Kurrachee, have been already run off, and the results are now being tabulated for printing. Specimen tide-curves of the Southern Indian, Pacific, and North Atlantic Oceans, the English Channel, and the Mediterranean, will also be exhibited to show the universality of the system of prediction by the instrument.

AMONG those on whom the honorary degree of LL.D. was conferred in the Senate House at Cambridge on Tuesday were Mr. Justice Grove, Dr. W. Spottiswoode, Prof. Henry J. S. Smith, Prof. T. H. Huxley, and Mr. H. C. Sorby.

PROF. HUXLEY has been elected a corresponding member of the Paris Academy of Sciences, in the section of Anatomy and Zoology, in succession to the late Prof. von Baer; and M. Schiaparelli in the Section of Astronomy, in place of the late M. Tisserand.

THE death is announced, on the 9th inst., of Dr. Moore, who for more than forty years has filled the office of Curator of the Botantic Gardens, Glasnevin, Dublin. He was a native of Dundee, and commenced the study of botany under the late Dr. Mackey, Curator of the College Botanical Gardens, whose place his eldest son, Dr. F. W. Moore, now fills. He was for some time employed on the geological survey of Ireland before he was appointed Curator of the Royal Dublin Society's Gardens at Glasnevin. He pursued the study of botany with great ardour, not only at home, but in various parts of the Continent. Among his works were "Notices of British Grasses," "Irish Hepaticæ," and "Irish Mosses."

IT is proposed immediately to establish a zoological station on the Aberdeen coast, in connection with the natural history laboratory of the University, similar to those already instituted for the Universities of Paris, Vienna, and Leyden. The objects of such a station are:—1. To supply the laboratory with fresh animals for purposes of teaching and research. 2. To enable students to become practically acquainted with natural history, and to afford them opportunities of advanced study and independent research, during the vacations. 3. To afford means for the exhaustive study of the marine fauna. For the establishment of such a station on the smallest possible scale it is necessary to have—(1) A movable shed or house with suitable fittings; (2) a large fishing boat and a small two-oared boat; (3) nets and dredges; (4) aquaria glassware and miscellaneous apparatus; (5) the services of a fisherman and a boy for part of the year. For the purchase of boats and apparatus a sum of 250*l*. is required,

and for wages, &c., at least 75*l.* annually. Lord Roseberry has given a donation of 50*l.*, and other subscriptions raise the total sum already obtained to 180*l.* It is not creditable to this wealthy country that it possesses no zoological station, and we trust our readers will do what they can to assist in raising the moderate sum required. Subscriptions may be sent to Mr. G. J. Romanes, 18, Cornwall Terrace, Regent's Park, N.W.

A NEW work is announced by Prof. Boyd Dawkins, on "Early Man in Britain and His Place in the Tertiary Period." In this the results of geological and archæological research, so far as they relate to the history of man in this country, will be placed before the reader in a connected narrative. Man will be treated as the central figure in the tertiary period, and the various changes in geography, climate, and living forms which preceded his arrival in Britain, will be examined, as well as those changes in his environment which took place after he appeared in Europe. His antiquity, his relation to the glacial period, and to existing peoples, and his manner of life, will be discussed, as well as the distribution of the Iberic and Celtic races, their manners and customs, their progress in civilisation, and the extent to which they were influenced by the civilised nations of the Mediterranean. It is the principal object of this work to give a picture of man isolated in Britain, from his first arrival down to the Roman invasion. It will be largely illustrated with maps and engravings. The work will be published by Messrs. Macmillan and Co.

MR. RUDLER has succeeded to the place of the late Trenham Reeks, in the Geological Museum, Jermyn Street.

IN an appreciative article on Sir Henry Bessemer, *à propos* of his knighthood, the *Times* gives some striking statistics to show the vast advances made in the production of steel since the adoption of the Bessemer process:—"Prior to this invention the entire production of cast steel in Great Britain was only about 50,000 tons annually, and its average price, which ranged from 50*l.* to 60*l.* per ton, was prohibitory of its use for many of the purposes to which it is now universally applied. In the year 1877, notwithstanding the depression of trade, the Bessemer steel produced in Great Britain alone amounted to 750,600 tons, or fifteen times the total of the former method of manufacture; while the selling price averaged only 10*l.* per ton, and the coal consumed in producing it was less by 3,500,000 tons than would have been required in order to make the same quantity of steel by the old or Sheffield process. The total reduction of cost is equal to about 30,000,000*l.* sterling upon the quantity manufactured in England during the year; and in this way steel has been rendered available for a vast number of purposes in which its qualities are of the greatest possible value, but from which its high price formerly excluded it. During the same year the Bessemer steel manufactured in the five other countries in which the business is chiefly conducted—namely, the United States, Belgium, Germany, France, and Sweden—raised the total output to 1,874,278 tons, with a net selling value of about 20,000,000*l.* sterling. The works in which these operations were carried on were eighty-four in number, and represent a capital of more than three millions. According to the calculations of Mr. Price Williams, who has made the endurance of rails a matter of careful study, the substitution of Bessemer steel for iron for this purpose alone will produce a saving of expenditure during the life of one set of steel rails on all the existing lines in Great Britain of a sum of more than one hundred and seventy millions sterling. It may safely be said that there is no other instance in history of an analogous impetus to manufacture, or of an analogous economy, being the result of the brain-work of a single individual; still less is there an instance of such results being realised while the inventor was living to enjoy the fruits of his labours, and able to work in fresh directions to increase the benefits which he had already conferred upon his country and upon mankind."

THE enterprising Birmingham Natural History and Microscopical Society have again arranged a marine excursion, this time to Falmouth, during next month, on a somewhat similar principle to those to Arran, which proved so successful in the last two years. Facilities will be afforded for dredging excursions and for land excursions to investigate the botany and highly interesting geology of the district. The botany of the district is very peculiar and interesting, and the geology is unique in the British Islands, Kynance Cove and the Lizard being within easy reach of day excursions from Falmouth. During the summer season a most interesting series of observations may be made on the microscopic larval forms of marine life (hydroids, echinoderms, annelids, &c.), which abound in the sea, and may at this time readily be taken by the tow net. A small steamer will be chartered, which will economise time and add to personal comfort. The marine fauna of the Cornish coast is exceedingly rich and varied. The time for the excursion will be from the 5th to the 14th or 21st of July.

PROF. VIRCHOW has returned to Berlin from Asia Minor, where, as our readers are aware, he had taken part in Dr. Schliemann's excavations. The learned professor was received with great honours at Athens. The Medical Faculty of the High School of that city presented him with the honorary doctor's diploma, and the Medical Society of Athens elected him an honorary member.

IN digging a channel in the neighbourhood of Lake Neuchâtel, a lacustrine canoe, very nearly seven metres long, has been found. It has been placed in the Cantonal Museum.

IN addition to the list of quite recent earthquakes we gave last week, we now have reports of two more. At Aachen (Aix la Chapelle) several shocks were felt on May 26, soon after 8 P.M., which seemed to proceed in the direction from west to east; and at Idstein (in the Prussian province of Nassau) a violent shock occurred on May 27, about 1 A.M.

M. DE LESSEPS has accepted the chairmanship of a committee for arranging the commemoration of the eighteenth centenary of the great eruption of Vesuvius in 79, when Pliny lost his life, and Pompeii and Herculaneum were destroyed. According to the most trustworthy records it was on the 23rd of August that this unexpected event took place.

M. CLAMOND, the inventor of a thermo-electric pile, has succeeded in producing a current strong enough to work a Serrin regulator with tolerable success. The expense is only 7 kilogrammes of coals per hour, and the appearance of the battery reminds one of an ordinary furnace.

THE Paris Academy of Meteorological Ascents has inaugurated the series of its aërial excursions. The first took place at St. Mandes and the second at Arcueil on the occasion of the opening of the École Laplace. The ascensionists propose to take photographs from the car in order to ascertain the position of the balloons and make a verification of the laws of barometric height. The original idea of this difficult operation may be attributed to Leverrier. Each of these ascents will be followed by the publication of diagrams and scientific results obtained. They are prefaced by a lecture, given by a member of the association, on the practice of aëronautics.

FROM June 7 up to the end of the month the exhibition of Beaux Arts at the Paris Palais de l'Industrie will be lighted every night by electricity. The motive power is supplied by 262 Jablochkoff electric lights. 120 have been distributed in the

gardens where statues are exhibited; 142 in the saloons where pictures are suspended on the walls. The 120 candles are surrounded by opaline globes, which diminish the total effect, but the general illumination is satisfactory. The other 142 have been placed in translucent glass spheres, which leaves the light its original force. The appearance of the pictures is splendid and the general impression is exceedingly favourable. It is supposed that the garden could well be arranged shortly according to the same system, and the illumination will be unrivalled in brilliancy. The partial extinctions are very few and generally very easily repaired. The motive force is supplied by four steam-engines placed in a shed at a distance, and is estimated at 300-horse power (seventy-five for each motor). The consumption of coal and other expenses are very small in comparison with the receipts which were more than 200*l.* for the first evening. It is divided in two equal parts, one for the Government and the other for the Jablochkoff Company. But the speculation cannot be said to be a paying one owing to the expenses of installation. The length of insulated wire is about 42,000 yards at a shilling each, and the other expenses in proportion. But it is supposed that the scientific exhibition will inherit the bargain and the electric fixtures, which are said to be worth 20,000*l.* will be in constant use up to the Month of November.

FROM Friedländer and Son, of Berlin, we have received two very full Catalogues of works in Geology and Geognosy, which we commend to all interested in these subjects.

IN reference to a statement in the *Globe* that the prediction of an earthquake to happen on or about May 21 was falsified, a correspondent, Mr. Frank Barnard, writes that on that day he felt the movement of an earthquake at Hastings, at 12 noon. He describes it as a quivering of the ground, slight, but too palpable to pass unheeded, communicating a quiver to his whole frame such as he never felt before. He forwards us a cutting from his sketch-book, on which he pencilled at the time a record of the occurrence.

IN reference to Mr. Hosie's article in last week's NATURE, on Chinese Observations of Sun-Spots, a correspondent writes that Mr. Sayce, in his "Babylonian Literature," shows that more than 4,000 years ago it was recorded in the library of Nineveh that the sun was spotted on the first day of the Chaldean year, "from which," says a *Times* reviewer, "we may infer the presence of an unusually large spot." We may, our correspondent thinks, infer more—the presence of spots.

MR. R. ETHERIDGE has written to the *Times* on a boring made by the New River Company at Ware in Herts, in which it was found that the Gault at a depth of 800 feet rests upon the Upper Silurian rocks (the Wenlock Shale), richly fossiliferous, dipping at an angle of 40 deg., but to what point of the compass is not at present known. The *Geological Magazine* for June reprints the letter and appends a list of the fossils found in the cores of the Wenlock.

WHEN King Victor Emmanuel took possession of Rome he left the Roman Observatory in the hands of the late Father Secchi, out of respect for his exceptional merits. When Father Secchi died, the Pope appointed his successor, who took possession of the establishment and refused to leave the place. He has been expelled, however, *manu militari*.

THE Roman Alpine Club has decided to send an excursion to Etna, which will leave Rome on July 1. Intending excursionists are directed to address the Secretary of the Roman section of the Italian Alpine Club before the 15th instant, as preparations are required for the comfort and safety of the excursionists. We believe that any one, irrespective of nationality, can join the excursion. The travelling expenses from Rome to Catania will be diminished by one-half, owing to the liberality of railway and steamer companies. The duration of the excursion will be at least seven days.

WE have received several numbers of the *Naturalist*, the journal of the Yorkshire Naturalists' Union, from which we see that the many societies composing that union are as active as ever. A most interesting series of excursions has been arranged for the summer.

M. E. MOREL, who has been Belgian Consul at Shanghai for many years, has informed the *North China Herald* that his Government, with the view of bringing the manufacturers of Belgium into greater prominence, contemplate the establishment at that port of a permanent museum in which specimens of all descriptions of Belgian manufactures and produce will be exhibited. It is believed that about 1,000*l.* per annum will be expended on this object.

THE additions to the Zoological Society's Gardens during the past week include a Rhesus Monkey (*Macacus erythræus*) from India, presented by Mr. J. Beech; a Golden Eagle (*Aquila chrysaëtos*) from the Western Hebrides, presented by the Earl of Dunmore, F.Z.S.; a Red and Yellow Macaw (*Ara chloroptera*) from South America, presented by Miss C. Cattlin; two Common Kingfishers (*Alcedo ispida*), British Isles, presented by Mr. W. W. Cobb; a Common seal (*Phoca vitulina*), British Isles; three Javan Peafowls (*Pavo spicifer*) from Burmah, deposited; three Maned Geese (*Bernicla jubata*) from Australia, purchased; an Eland (*Oreas canna*), a Canadian Beaver (*Castor canadensis*), a Great Kangaroo (*Macropus giganteus*), a Red Kangaroo (*Macropus rufus*), a Bennett's Wallaby (*Halmaturus bennetti*), born in the Gardens; four Amherst Pheasants (*Thaumalia amherstiæ*), three Egyptian Geese (*Chenalopex ægyptiaca*), bred in the Gardens.

SCHLIEMANN'S TROJAN EXCAVATIONS

THE *Times* of Tuesday contains several letters from Dr. Schliemann, describing the researches he has been recently making in the Trojan country in company with Dr. Virchow of Berlin, and M. Burnouf, of Athens. They endeavoured to ascertain the geological character of the plain of Troy, by sinking shafts in different parts between Mount Hissarlik and the Hellespont. Dr. Schliemann states:—"We obtained everywhere the same result—viz., below the clay soil a thick layer of coarse or fine river sand, and below it the very compact dark-brown clay of the plain. But the most important result was obtained by the shaft we sunk in the Stomalimne, mentioned by Strabo, which is an easily recognisable swamp, situate between the mouths of the rivers; it slopes abruptly from the plastic clay of the plain to a field of sand which is nearly on a level with the sea. Excavating there, we found below the layer of sand, which is hardly an inch thick, a layer of plastic clay, about 16 inches thick, which is perfectly the same as in the plain, and below it a dark-blue sand containing putrified vegetable matter, which can leave no doubt that here existed a swamp. The upper part of this layer of blue sand is exactly on a level with the sea and with the adjoining inlet, the water of which is brackish and has no current. Having dug in this blue sand a large hole two feet deep, we saw the water filtering from all sides through the sand and soon filling the hole completely, and thus the water's surface was on a level with both inlet and sea; but this water was sweet and drinkable. In no one of our shafts sunk elsewhere did we discover the slightest trace of the sea having ever sojourned there; everywhere we found only the produce of sweet water. Thus it is evident that the soil of the plain of Troy has been produced by sweet water, and that this deposit is anterior to the existence of both the Scamander and the Simois, the more so as the modifications produced by these rivers are but very slight." Therefore he maintains the theory that at the time of the Trojan war the sea formed a deep gulf in the Plain of Troy, that the later Ilium (Hissarlik) was too near the Hellespont, and no space left for the great deeds of the "Iliad"; that consequently the two cities

could not possibly be identical—is now exploded and can never be revived again. Both Professor Virchow and Mr. Burnouf have accepted Dr. Schliemann's theory that the immense bed of the small and insignificant rivulet Kalifatli-Asmak, which has no running water except during the inundations in winter—that this river-bed, which has in many places a breadth of from 660 ft. to 825 ft. —is identical with the ancient bed of the Scamander.

Dr. Schliemann then describes the results of his excavations on the gigantic tumuli called Udjek-Tepé and Besika-Tepé. He now inclines more and more to the conviction that these and other immense Trojan tumuli were no real tombs, but mere memorials erected in commemoration of some great event. "They certainly existed at the time of Homer, who mentions four of them (those of Batieia, Æsyetes, Ilus, and Achilles) as real tombs, no doubt because, in his time, similar conical tumuli were erected at Sardis and elsewhere on the Asiatic coast over the ashes of great men."

In continuing his excavations at Troy, Dr. Schliemann found two other treasures of Trojan gold jewellery, and Ilium, he states, appears now exhausted. Dr. Virchow and M. Burnouf are astonished at the monstrous quantity of bricks, which solely occur in the burnt city. The three explorers are convinced that these bricks must have been slightly burnt in an oven before being used for building.

Mr. Sayce, in a letter in yesterday's *Times*, states that the markings on a fragment of pottery, a *fac-simile* of which was sent him by Dr. Schliemann, are rude attempts to imitate cuneiform characters on the part of a potter who was unacquainted with the meaning of the latter. "As is well known, the specimens of Phœnician art found in the Mediterranean frequently bear rude representations of Egyptian hieroglyphics figured for the sake of ornament, and grouped in such a way as to show that the artist had not the faintest idea of their signification. If my view of the markings on the piece of pottery discovered by Dr. Schliemann is correct, it becomes certain that some kind of prehistoric intercourse was carried on between the Troad and the populations who employed the cuneiform system of writing, and since the remains found at Hissarlik show little or no trace of Assyrian or Phœnician influence, the intercourse must be assigned to the older Babylonian period. Five years ago I suggested that some of the designs on the terra-cotta disks from Hissarlik might be rude imitations of designs on archaic Babylonian cylinders. I may add that Mr. Newton, to whom I showed the *fac-simile* sent me by Dr. Schliemann, thought my view of it very possibly right."

In connection with the above the *Times* states that a recent number of the *Norddeutsche Zeitung* stated that the Chinese Ambassador at Berlin, Li Fangpao, well known in his own country as a great scholar, has lately read as Chinese the inscription on a vase found by Dr. Schliemann in the lowest stratum of his excavations at Hissarlik, and figured on p. 50 of the introduction to his "Troy and Its Remains." Li Fangpao is quite confident that the unknown characters, which recur again and again on the Trojan antiquities, especially on the terra-cotta whorls, are those of his native tongue, and gives as the purport of the inscription, that about B.C. 1200, three pieces of linen gauze were packed in the vase for inspection.

With reference to this Mr. Sayce states that the authority of the Chinese ambassador, high as it is, will never persuade any one acquainted with the characters of the Cypriote syllabary that the characters found on some of the objects from Hissarlik are Chinese. As was stated in a *Times* leader, they belong, Mr. Sayce repeats, to the curious syllabary which seems to have been used on the coasts of Asia Minor and in the islands of the Ægean before the introduction of the simpler Phœnician alphabet, and which continued to be employed in conservative Cyprus down to a late date.

ON THE ORIGIN OF THE SOLAR PROTUBERANCES

WE take the following from a communication made by Herr Spörer to the Berlin Academy on November 7:—

"Simultaneously with the minimum of sun-spots the protuberances have been also insignificant hitherto, but since the middle of this year (1878), while the spot minimum continues to last even far beyond expectation, important protuberances have yet appeared, and among them some from which important deductions may be drawn with tolerable certainty.

"According to my observations of the year 1871 I had distinguished two classes of protuberances, viz., the ordinary hydrogen protuberances, and the flame-like protuberances which are remarkable on account of their intensity and pointed forms. In the latter ones, apart from the H lines and D_3, the magnesium lines may be easily recognised even with the smaller 5-inch telescope, which was then and is now at my disposal; other lines are less easily recognised. When Secchi agreed with me in this division of protuberances he chose the name of 'metallic' ones for the second kind, because the lines of metallic elements principally appear in them, apart from the H lines and D_3.

"No doubt we may suppose that many of the ordinary hydrogen protuberances originate through *storms* forcing up the hydrogen sea in gigantic *whirls* and *waves*, and I have also succeeded in finding examples confirming this, as the changes observed took place entirely after the manner corresponding to our waterspouts; this, however, does not exclude that many of the hydrogen protuberances originate through eruptions from the interior of the sun's body. We are still more inclined to look upon the flame-like protuberances as *eruption* products. I had considered also whether for the explanation of these, electricity might not be taken into account, particularly since then the quick shooting up and the quick change of the formations would not have to be explained merely by the motion of masses, and the over-great velocity would not be so surprising. Indeed, observed zigzag lines of communication between neighbouring flame-like protuberances had suggested the thought of *electric discharges*.

"The thought that bright protuberances do not start from the surface, nor yet from the hydrogen envelope, but rather that they are formed only at a certain height, therefore that perhaps at the low temperature existing at greater heights, *chemical combinations* take place, and that only by these the intense flaring up is produced—this thought may doubtless not be designated as a new one, but no forms of protuberances have been published yet which would decidedly favour this view."

Herr Spörer then quotes from numerous Italian publications a considerable number of protuberances which appeared *perfectly detached* from the surface, and says he could considerably augment these examples from his own observations. But the objection may be made to these cases that the formations described are only the remains of larger ones which previously had their origin at the sun's surface. This objection is perfectly justified since observations have proved often enough that brightly luminous protuberances became partly obscured, and particularly that the foot of a protuberance disappeared while the upper part remained visible.

It is necessary therefore to adduce such examples where the proof may be furnished with certainty that a luminous formation which is observed detached from the surface, did not originate *at* the sun's surface. Now Herr Spörer together with Herr Kempf has observed protuberances of this nature in July and August last year; he deferred their publication in the hope of being able to obtain more examples; this hope was annihilated for the present through the beginning of the unfavourable season, and hence the observations which had been made were made known. There were altogether three observations of this kind, which Herr Spörer describes and represents by illustrations; here we must confine ourselves to reproduce the one case which was the most favourable one to his theory, and which was observed on July 22 from 5h. 30m. until 6h. 50m.

The protuberance appeared in lat. 35°–40° south, and attained a height of 46″, or 34,000 kilometres. First of all it was seen in one point in the shape of an eruption, which, by the action of storms, was partly deviated to the left. In this direction an arc appeared, which expanded further to the left (possibly always in consequence of storms), until later on it touched the sun's surface, and thus spanned a dark segment. Intensely bright rays were remarkable about 5h. 47m. when they first appeared, and which proceeded from the highest part of the arc segment in a vertical direction, and quite detached from the solar surface. The direction of the rays did not permit the idea that they might have been torn off from the protuberance on the right by the action of storms perhaps, or otherwise. Then a larger mass was formed by these rays, whereupon extremely quick and varied changes took place, the exact observation of which was impossible, since the slit of the spectroscope could not be widened and therefore only a part of the protuberances could be observed at a time. At 6h. 12m. the complete arc was seen, the denser part over the middle had become a little looser, but glistening points were again present, standing perpendicular upon the arc; the formation had assumed larger dimensions at 6h.

23m. To the right a new ray had formed, which attained a much greater height than the other parts of the protuberance, viz., to 61", or 46,000 kilometres, and which lasted only for a short time.

It might perhaps be thought possible that the vertical rays over the middle of the segment and the larger protuberances originating there, had yet been in connection with the sun's surface, the dark segment having formed the foreground, so that dark and dense gases of this segment might have hidden the parts behind them from view. But then the segment ought to have appeared as a sun spot later on, if it had not happened to appear at the very extreme limb. On account of the enormous dimensions a spot of this kind could not have disappeared entirely until the following day, on July 23, therefore, at least some remains should have been observed really as a spot. But there were not any spots on the sun's disk neither on July 23 nor on the following days, except two small spots on the northern hemisphere on July 26. At the same time we might remark that in the high southern latitude of the protuberance so large a spot has never appeared before; this we know by experience.

The examples of July 24 and of August 9 are equally important, if indeed less grand in proportions. In both cases the protuberance, seen detached from the solar surface, could not be due to the action of storms, but, like the one described above, rather appeared to favour the hypothesis of the *origin* in higher regions.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

THE Cambridge Museums and Lecture Rooms Syndicate have issued their thirteenth annual report, in which they give details of the progress made in the buildings in course of construction. They report that they have no hope that the necessary expenditure upon the various departments of the museums can again be brought within the limits of the existing allowance for their maintenance. Having regard to the present state of the University finances, they have directed a curtailment of expenditure in all directions. This economy, however, although unavoidable at present, will, if persisted in, lower the standard of scientific education in the University, for it will be impossible to maintain the departments in their present state of efficiency. They hope that at no distant date the University will be in a position to increase the fund to a sum sufficient for their proper maintenance on the enlarged scale rendered necessary by the erection of the new buildings and the increased number of students. Appended to the report are the reports of the various professors, the superintendent of the Museums of Zoology and Comparative Anatomy, the Strickland Curator, and the Trinity Prælector of Physiology on the conditions of their several departments.

A MEETING of the curators of the University of Edinburgh was held on Friday, the 6th inst., with reference to the vacancy in the Chair of Mathematics caused by the death of Prof. Kelland, and it was resolved to hold another meeting early next month as to the appointment of a successor. Meantime, it is requested that the applications of intending candidates, accompanied by any testimonials desired to be submitted, be forwarded by Saturday, July 5. The emoluments, which are derived from a fixed endowment and from class fees, amount to between 1,200*l*. and 1,500*l*. per annum. Any details desired can be obtained from the Secretary to the Senatus Academicus.

THE ninth Annual Report of the Wellington College Natural History Society has to record a good deal of satisfactory work done, as is evident, indeed, from the very full lists and reports appended in the various departments. We should like to see the recommendation adopted given to those Fellows who do not play cricket, that they should devote themselves in the afternoons to the observations of birds and insects. A very fair proportion of the members, however, seem to do work.

THE new university building of Marburg was inaugurated on May 29 in the presence of Dr. Falk, the German "Cultusminister."

SOCIETIES AND ACADEMIES

LONDON

Royal Society, May 15.—"On the Capillary Phenomena of Jets," by Lord Rayleigh.

In this paper are given the results of observations and their discussion on water issuing under varying pressure from orifices of various shapes.

Geological Society, May 28.—Henry Clifton Sorby, F.R.S., president, in the chair.—Edward Garlick was proposed as a Fellow of the Society.—The following communications were read:—On the endothiodont reptilia, with evidence of the species *Endothiodon uniseries*, Owen, by Prof. R. Owen, C.B., F.R.S. The author referred to the characters assigned by him to his *Endothiodon bathystoma*, which had the alveolar borders of both jaws toothless, perhaps covered with horn during life, as in the Chelonians; whilst within this border there were three series of teeth both in the palate and the mandible. He next described a new species, under the name of *Endothiodon uniseries*, founded upon the fore-half of a skull, having only a single row of teeth in the palate, a character which may prove to be of generic importance. The author finally discussed the relationships of this genus, which he regarded as belonging to the order Anomodontia, and as showing, like *Oudenodon*, traces of derivation from *Dicynodon* in the presence of caniniform processes in the upper jaw. The development of teeth interior to the alveolar margins in both jaws was to be regarded as a character of family value, and the author remarked upon the interest of the continuance of a common ichthyic and batrachial dental character in exceptional cases among the reptilia up to the establishment of the crocodilian type, above which, in the vertebrate series, calcified palatal teeth no longer appear.—Note (third) on *Eucamerotus*, Hulke, *Ornithopsis*, Seeley, = *Bothriospondylus magnus*, Owen, = *Chondrosteosaurus magnus*, Owen, by J. W. Hulke, F.R.S.—Description of the species of the ostracodous genus *Bairdia*, M'Coy, from the carboniferous strata of Great Britain, by Prof. T. Rupert Jones, F.R.S., and James W. Kirkby. The long persistence of the genus *Bairdia*, from the silurian period to the present day, and its essentially *marine* character, were first noticed; also the relatively rare occurrence of any species of *Leperditia*, *Beyrichia*, and *Kirkbya* (associates of *Bairdia* in carboniferous strata) in fresh-water or estuarine beds. *Carbonia*, on the other hand, was confined to the fresh or brackish waters in which the coal-measures were formed. The difficulty of defining the species of *Bairdia* from carapace-valves alone, without limbs and soft parts, and the possibility of several genera being grouped under this head, were mentioned. The species of *Bairdia* described and figured in this paper were, it is believed, all that have been found in the British carboniferous rocks, with the exception of M'Coy's *B. gracilis*. Two of Count Münster's Bavarian *Bairdiæ*, from Hof, have not yet occurred with us; neither have four of Dr. d'Eichwald's Russian carboniferous species, nor the Australian *B. affinis*, Morris. Including these, there are twenty-three known carboniferous species of *Bairdia*. Seven of these are recurrent in the overlying permian limestones, which have yielded twelve species of this genus. With six silurian forms, there are altogether thirty-four recorded palæozoic species of *Bairdia*.—Report on a collection of fossils from the Bowen River coal-field and the limestone of the Fanning River, North Queensland, by R. Etheridge, jun., F.G.S.—On a fossil *Squilla* from the London clay of Highgate, part of the Wetherell collection in the British Museum, by H. Woodward, F.R.S.—On *Necroscilla Wilsoni*, a supposed stomatopod crustacean from the middle coal-measures, Cossall, near Ilkeston, Derbyshire, by H. Woodward, F.R.S.—On the discovery of a fossil *Squilla* in the cretaceous deposits of Hâkel, in the Lebanon, by H. Woodward, F.R.S.—On the occurrence of a fossil king-crab (*Limulus*) in the cretaceous formation of the Lebanon, by H. Woodward, F.R.S.

Zoological Society, June 3.—Prof. W. H. Flower, LL.D., F.R.S., president, in the chair.—The Secretary exhibited and made remarks upon two volumes of original drawings of the birds of India, which had been deposited in the Society's Library by Brigadier-General A. C. McMaster. The volumes contained about 270 figures of the birds of India, most of which had been drawn by soldiers in General McMaster's house at Secunderabad.—Mr. Sclater exhibited and made remarks on a small collection of birds forwarded to him by Dr. A. Döring, of the University of Cordova, in the Argentine Republic.—Mr. W. Ottley gave a description of the blood-vessels of the neck and head of the ground hornbill.—Mr. Edward R. Alston read a paper on the specific identity of the British martens, in which he pointed out the distinguishing characters of *Martes sylvatica* and *M. foina*, and showed that the former species only is found in this country.—Messrs. Sclater and Salvin gave an account of the birds collected by the late Mr. T. K. Salmon in the State of Antioquia, United States of Columbia. Mr. Salmon's collections were stated to have been very extensive, having been the product of

some five or six years' assiduous collecting, and to have contained altogether about 3,500 specimens of birds, which were referable to 469 species.—Mr. G. French Angas gave an account of the land-shells collected by the late Dr. W. M. Gabb, in Costa Rica. The collection was stated to contain examples of forty-two species, of which ten or twelve were believed to be new to science.

Anthropological Institute, May 27.—Mr. E. Burnett Tylor, D.C.L., F.R.S., president, in the chair.—A paper by Mr. Hodder M. Westropp was read, entitled notes on fetichism, in which the views of Prof. Max Müller on the subject of fetichism as expressed in his late lectures on the development of religion were combated, and Mr. Westropp advanced an opposite theory of his own. Having stated all the points of difference between himself and Prof. Max Müller, the author explained his position thus:—that those who believe in a primordial fetichism must take it for granted that human beings passed through a rude and primitive phase when their minds were naturally and instinctively endowed with certain vague ideas of spirits and ghosts, which seem to be the spontaneous outgrowth of minds in a rude and primitive condition in all countries and in all ages. In the same way it must be taken for granted that all human minds have passed through a state of infancy.—A paper was also contributed by Mr. J. Matthew, of Little River, Victoria, on the Kabi dialect of Queensland. Although the Australian dialects are usually spoken of as agglutinative, the author considered that if it were possible for a language to be classed as isolated, although having the majority of its words composed of two syllables, such a language is Kabi.

Mineralogical Society of Great Britain and Ireland, June 3.—Prof. T. G. Bonney in the chair.—The election of fourteen Corresponding Members, eight Ordinary Members, and two Associates, was announced.—The following papers were read:—On abriachanite, a new Scottish mineral, by Prof. M. F. Heddle and Dr. W. H. Aitken.—On haughtonite, a new mica, by Prof. M. F. Heddle.—On brechite and xantholite from Scotland, by Prof. M. F. Heddle.—On christophite from St. Agnes, Cornwall, by J. H. Collins, F.G.S.—Minerals from Japan, by John Milne.—On some gold occurrences, by the Rev. J. Clifton Ward, F.G.S.—Additional note on penwithite, by J. H. Collins, F.G.S.—Measurements of angles of basaltic columns from the Giants' Causeway, by Professors Jellett and O'Reilly.

PARIS

Academy of Sciences, June 2.—M. Daubrée in the chair.—A telegram from the Emperor of Brazil stated that Tempel's comet had been seen on the 24th and 25th ult.—On the magnetic impenetrability of iron, by M. Jamin. The experiments prove that a given current through coils magnetises a bar much less when the latter is inclosed in a tube than when exterior to the tube (placed beside it); and the tube is more magnetised in the former case than in the latter. 6 mm. of concentric thickness of iron suffices to arrest almost completely the magnetic effect of an exterior spiral.—On the ultra-violet limit of the solar spectrum, by M. Cornu. Taking fine days, a collodion of constant composition, and a constant time of exposure, very comparable observations are had. The extent of the spectrum diminishes with the altitude of the sun, which tends to prove that the limitation is due to absorption by the atmosphere. The furthest limit obtained was at wave-length 293; this was only twice, on June 24 and August 18, 1878, about noon. M. Cornu discusses the causes of error, the conditions of extending the limit, and the variation of the limit with the height of the place of observation. The limit is pushed back one-millionth mm. in wave-length as you rise 663·3 m. (a small gain; becoming only 6 millionth mm. for 4,000 m. altitude, or about half the difference between winter and summer).—On alkaline amalgams, and on the nascent state, by M. Berthelot. A thermal study of the reducing action of these amalgams on organic compounds. They always liberate, in hydrogenising reactions, more heat than free hydrogen would, the respective excesses for amalgams of sodium and potassium being 32·8 and 27·5.—On stannpropyls and isostannpropyls, by MM. Cahours and Demarçay.—On the quantity of nitric acid contained in the water of the Nile before and after flood, by M. D'Abbadie. Having observed that thunderstorms accompanied most of the Ethiopian rains, he thought traces of the nitric acid formed would be found in the river at Cairo. Samples were taken before, during, and after the flood time, at about two months' intervals from July 10. The several numbers (for nitric acid) were, unexpectedly, 0·01, 0·0038, and 0·002 grammes per litre (of the last there is some doubt). He thinks the flooding of the Nile offers abundant material for study.—On the origin of sounds in the telephone, by M. Du Moncel. In most experiments showing that speech may be reproduced simply by a magnetic core surrounded by a helix, a microphonic transmitter with battery has been used. M. Du Moncel now shows the effect may be had with the induced currents of the Bell telephone, (made by Breguet). The receiver was a small strongly magnetised piece of watch-spring, fixed to a deal board, and surrounded by a small helix of fine wire. The diaphragm in the telephone, serving as armature, exalts the magnetic force of the bar, and is itself affected by the vibrations of the telephonic case fixed to one of the ends of the bar.—On the inter-oceanic maritime canal, by M. de Lesseps. He recounts the steps leading to the recent decision of the Congress; speaks hopefully of the work to which he is designated, and announces his purpose to make an appeal in all countries for a capital of 400,000,000 francs.—On the lines of sodium vapour, by Mr. Lockyer. Sodium vapour, after long distillation in vacuo, no longer gives the line D near the metal.—Widmanstaetten figures on artificial iron, by Prof. Lawrence Smith. He obtains them by heating a siliciuret of iron on lime with the gas blowpipe; the metallic button, after cooling, is placed in warm nitric acid.—M. Schiaparelli was elected Correspondent in Astronomy in room of M. Tisserand, and Prof. Huxley in Anatomy and Zoology in room of M. de Baer.—On a mode of transformation of ruled surfaces, by M. Mannheim.—Solar observations during the first quarter of 1879, by M. Tacchini. Of 35 days utilised, 32 figure without spots and cavities. The mean frequency per day was 0·33 (relative proportion greatest in January); this is less than in 1878, showing extension of the minimum. The hydrogenic protuberances also show diminution; they are nearly all in the northern hemisphere; the faculæ in the equatorial zone.—New arrangement for increasing the sensibility of the vibrating plate in the telephone, by M. Decharme. This consists in fixing the plate by its centre point alone, instead of by its border.—On a combination of alumina with carbonic acid, by MM. Urbain and Renoul. The composition (very unstable) is alumina, 52, carbonic acid, 11, water, 37; a hydrated sub-carbonate of alumina. Prof. Smith stated that the mineral, *Dawsonite* found at Montreal, is composed of carbonate of alumina and soda.—Influence of the pneumogastric and action of digitaline on the movements of the heart in sharks, by M. Cadiat. Digitaline acts as poison directly on the heart, causing tetanisation of the ventricle and diastole of the auricle.—On evolution of the embryo in eggs subjected to incubation in warm water by M. Dareste. He got such evolution to some extent in repeating the experiment of Reaumur (whose results were negative).—On a case of trichinosis observed in a young hippopotamus of the Nile, which died in captivity, by M. Haeckel.—M. Delecheneau described a modification of the phonograph.

ELECTRIC LIGHTING

L'Éclairage Électrique. Par le Comte Th. du Moncel. (Paris: Hachette and Co., 1879.)

Electric Lighting and its Practical Application. By J. N. Shoolbred, M.Inst.C.E. (London: Hardwicke and Bogue, 1879.)

The Electric Light in its Practical Application. By Paget Higgs, LL.D. (London: Spon, 1879.)

THE little work, which now appears amongst the numerous volumes of the "Bibliothèque des Merveilles," though containing much more of real information than many of the sketchy works of that popular series, is somewhat disappointing. Like the other writings which the Comte du Moncel has given to the world, it displays a remarkable amount of industrious compilation, but the arrangement of the matter collected is somewhat cumbrous. A far superior book to his recent work on the Telephone, it is nevertheless marred by the same occasional confusion of thought exhibited in that work. It contains, however, in a small compass, a good deal of useful information, and enough serious reading to make it pass as a scientific book.

After fifty pages of generalities the author settles down to discuss the different systems of magneto-electric machines and their comparative efficiency. Next comes a chapter on "*organes excitateurs* de la lumière électrique," which we discover to include carbons of various manufacturers, and materials for lighting by incandescence. Then follow three chapters on regulators, incandescent lamps, and electric candles; after that a *résumé* of the cost of electric lighting; and finally a capital chapter on its numerous applications.

With regard to magneto-electric and dynamo-electric machines, great pains have evidently been taken to give a fair account of most of the systems of importance. In this respect the present work contrasts very favourably with that of M. Fontaine, in which such a disproportionate amount of space is allotted to the Gramme machines. Beginning with the early machines of Nollet, Wilde, Holmes, and Ladd, the successive inventions of Gramme, Siemens, de Meritens, Wallace, Brush, and Lontin are carefully explained, excellent woodcuts of most of these being appended. The "distributing" machines of Lontin, Gramme, and Jablochkoff are also noticed. We take exception to the statement that the Wallace-Farmer machine is merely an enlarged copy of those of Wilde and Lontin. It differs essentially from the former, and in point of date was earlier in the field than the latter. If there be one machine more than another that it does resemble, it is the machine of M. Alfred Niaudet, of which M. du Moncel makes no mention. On the very important question of the relative efficiency of the various systems, M. du Moncel has nothing to say that is new, but simply reproduces the tabular results published by the authorities of Trinity House and by the Committee of the Franklin Institute. His treatment of the question of the cost of electric lighting is even less satisfactory, the figures obtained as the result of the most recent experiments on a large scale in Paris and London being entirely omitted.

In treating of Regulators the author employs a classification deserving of attention. They are divided into six categories, viz.: (1) Regulators founded on the attraction of solenoids, as those of Archereau, Gaiffe, Jaspar, and Brush; (2) those depending on movements worked by electromagnets, as the lamps of Duboscq, Foucault, Serrin, Siemens, and Rapieff; (3) those with large circular carbons, as the regulators of Wright and Reynier; (4) those depending on hydrostatic reaction, as Way's mercurial lamp; (5) those depending on the reaction of the current itself, producing mutual repulsion between the carbon poles; and (6), lastly, those with fixed carbons, such as the electric candle of Jablochkoff. Lamps on the principle of incandescence so-called are treated of under a different head. The plate-lamp devised by Wallace is not mentioned. The following account of the process of manufacture of the Jablochkoff candles is new, and will be read with interest:—

"The manufacture of these candles carried on on a large scale at the Avenue de Villiers, where six or eight thousand a day are made, is really very interesting, especially the manner in which the insulating portions are fashioned. Upon a marble table slightly oiled is spread, by means of a moulding instrument made of a toothed strip of zinc fixed so as to slide in a suitable frame, a thin layer of plaster of Paris mingled with sulphate of baryta, and mixed so as not to set rapidly. This plaster is placed in front of the moulding instrument, which is then moved over the marble slab in such a way as to form grooves and ridges about two metres long. After the moulding tool has been passed backwards and forwards several times, a fresh quantity of plaster is placed in front of the instrument, thus increasing the thickness of the ridges; and at the end of five or six operations of this kind the ridges have exactly the thickness of the teeth of the moulding-tool, or that required for the insulator. The sides of these insulating strips are naturally made slightly concave to receive the carbons, which are cylindrical."

An account of the condensers employed by M. Jablochkoff in conjunction with the alternate-current generators that feed a series of candles, will also be found of some interest. M. du Moncel states that, without these condensers, the candle which has the least resistance of the four on one circuit absorbs so much of the current, that the other three are put out.

We have noticed, in perusing the work, a number of minor blemishes, which, should the book reach a second edition, might with advantage be removed. Thus we are told on p. 13, that Humfry-Davy (*sic*), in 1813, made the first experiments on the production of the voltaic arc, and that this discovery was "completed" by Foucault by the substitution of gas carbon for wood charcoal. If we remember rightly, Sir Humphry Davy's experiment in the Royal Institution, as recounted in the *Philosophical Transactions* for 1809, were made in 1808. Foucault's suggestion came in 1844.

What are we to understand by the following statement on p. 6?—"The *tension* of a current, *which is often nowadays confounded* (these italics are ours) with the *potential*, is the property of the electric fluid which gives in some sort the impulse of the electric movement . . . ." This statement may be put by the side of another on p. 15, that it is possible "to augment the intensity of a gene-

rator at the expense of its tension by condensing the charges."

Passing on to details concerning the light itself, we are told that the heating of the positive carbon to a higher temperature than the negative (an effect which, by the way, depends also upon the diameters of the two carbons) by the battery current does not take place with currents of high tension produced by induction machines. The author makes Professors Ayrton and Perry responsible for the statement that the resistance of the arc is 255 ohms.

Again, on p. 25 we read that the *Bunsen's* cell was discovered in 1839 by *Grove!* And, on p. 34, that to ascertain the resistance of the circuit a rheostat is employed. We had hitherto imagined Prof. Bunsen's battery to be a somewhat later device than that of Sir William Grove, dating from 1842 or 1843, and that for all practical purposes the unreliable rheostat had long been superseded by reliable resistance-coils. We rub our eyes mentally over these little matters.

In one of the appendices some excellent remarks of Mr. W. H. Preece are transcribed entire. In another a brief account of Mr. Edison's patent is copied from the *Standard*, with the following comment:—"This patent, practicable or not, exhibits the usual ingenuity of Mr. Edison, says the *Standard;* for our part we cannot share this opinion, and can see nothing new in the patent. It is a crude idea which does not seem to us likely to lead to any important results."

There is little doubt that to a large class of readers an English translation of this work will be acceptable. It will, however, require careful revision by a competent editor, especially in those passages—numerous to an almost irritating degree—where the reader is referred to the previous works of the author. If this be done the book will fill a useful place at the present time, when so much ignorance prevails as to the nature of the electric light.

Mr. Shoolbred's "Electric Lighting" is an expansion of the papers read by him before the Society of Arts and elsewhere, and professedly deals chiefly with the question from the point of view of practical application. Hence we have in this volume not only the well-known results of experiments on the cost of the light in tabulated form, but also paragraphs on such outlying subjects as photometers, gas-engines, and water-motors. All the principal machines and lamps are briefly described, and many of them figured on lithographed plates. Under the heading of Electric Candles, those of De Meritens, Wilde, and Rapieff are mentioned in addition to the well-known Jablochkoff "candles." Some account is also given of the chief experiments recently made in this country on the various systems of lighting. The manufacture of the carbon pencils for producing the arc is very briefly treated: too briefly, considering that this is the very point in which there exists at present the greatest room for improvement.

Some of the expressions used by Mr. Shoolbred strike us as warranted neither by their scientific accuracy, nor by popular usage. Thus on p. 95 we find, on the question of the subdivision of the light, the following sentence: "The product of each electrical circuit may, it would appear, be fairly considered as the *unit of output.*" On p. 96: "The *output* of a machine with regulators does not readily divide itself." This term "*output*," which in these instances, and on p. 11, is used for quantity of current generated by the machine, occurs again on pp. 65 and 66 for the amount of light emitted! The statement on p. 50 that "the very production of the electric light depends upon the conversion of a certain amount of mechanical *duty* into electrical *force*," would certainly draw down the wrath of sticklers for scientific accuracy. The suggestion to produce the voltaic arc between incombustible electrodes so as to avoid the production of nitrous fumes, "and *the very fact* that the use of *carbon* electrodes led to the development of *such baneful emanations*," can hardly be endorsed as a piece of chemical wisdom.

These blemishes, however, and a prevailing inelegance of style, show that a general acquaintance with a scientific subject will not alone qualify its possessor to be regarded as an authority.

For general merit and usefulness the treatise of Dr. Higgs on the electric light in its practical applications will take high rank. Avoiding historical details and points of abstract theoretical interest, the author begins by describing the various lamps and "burners" devised for producing electric light; he then goes on to enumerate the various generators, and to discuss their relative efficiency and economy, illustrating every point where possible by carefully tabulated results of experiment; and concludes with a notice of various useful applications. Many sources of information have obviously been laid under contribution: the report of the Franklin Institute, that of Professors Houston and Thomson, and the very valuable paper of Mr. Preece on the question of multiplication of lights, being reproduced almost entire. The recent and instructive report of Dr. Oëlhausen is also quoted in the chapter on Commercial Aspects. Chapter viii. is devoted to electric "regulators," a term which we discover the author to apply to devices, not for regulating the arc, but for controlling the strength of the current. He rejects the term "regulator" in its usual application, preferring to speak of electric "lamps" and "burners." On page 196 is given a table of the various and singularly divergent measurements which have been made of the intensity of illumination of the Jablochkoff candle. A summary of the report of the Gas Light and Coke Company's Committee is also given, and the prejudiced nature of that document is clearly demonstrated. A few blunders require attention. Thus the formula on page 198 for estimating the useful effect of distributed lights is hopelessly wrong. Again, while there is on page 169 a statement that the light is proportional to the current, we find on page 214 a sentence which would lead us to imagine the author's opinion to be that the light was proportional to the fourth power of the current! We doubt, too, whether it has yet been shown that "the hissing noise produced by the electric arc is due to the formation of a vacuum round the incandescent points." The statement that "a tuning fork with its prongs two yards in length will vibrate less than once in two seconds" is misleading, and not necessarily true. These defects apart, the book is a good one; and the illustrations, which are numerous, strike us as being, for the most part, superior to the average of those of scientific books. But why should the

author advertise himself as the *author* of "Electric Lighting," which is the title—if we are not mistaken—of his *translation* of Fontaine's well-known work?

SILVANUS P. THOMPSON

THE DOLOMITE REEFS OF THE SOUTHERN TYROL AND VENETIA

Die Dolomit-Riffe von Süd-Tirol und Venetien. Beiträge sur Bildungsgeschichte der Alpen. Von Edmund Mojsisovics von Mojsvár. Pp. 552, with 30 Photographic Plates, 110 Woodcuts, and an Atlas in 6 sheets. (Vienna: Holder, 1879.)

THERE are few districts in Europe which have attracted so much attention from geologists as that which is described in the splendid monograph now lying before us. Whether we consider the richness and variety of the palæontological treasures yielded by the world-famed deposits of St. Cassian, the wonderfully-dissected volcanic centres of Monzoni and Predazzo, or the remarkable illustrations of the action of denuding forces still at work in the Alpine regions, as illustrated by the picturesque ruin-like masses of the dolomitic limestones and the singular earth-pillars of Botzen, the area must be admitted to be worthy of the celebrity which it enjoys among the cultivators of all branches of geological science.

The author of the present work possesses a remarkable combination of the qualifications necessary for the successful accomplishment of the task he has set himself. A daring Alpine climber, he has explored the most inaccessible recesses of the district during the summer months, while his winters have been devoted to the study of the grand assemblage of fossil-forms which he has brought together with such untiring industry. The manner in which Dr. Mojsisovics is performing this task of describing the enormous series of fossils of the Alpine Trias—an assemblage of forms possessing so many features of interest on account of the remarkable admixture of Palæozoic and Mesozoic types which it presents—is familiar to all palæontologists. He has shown that at Hallstadt and St. Cassian respectively we have evidences of the existence of two distinct life-provinces in the Triassic seas, and his monographs on the cephalopods of these two life-provinces, the first instalments of which have already appeared, have excited the greatest interest among naturalists, who were scarcely prepared even by the writings of von Hauer and other illustrators of the fauna of the Alpine Trias, for the new and remarkable varieties of the Ammonite type, now brought to light by the author of this work. The current number of the *Verhandlungen der k. k. geologischen Reichsanstalt*, of Vienna, contains an interesting summary of this new work, and shows that no less than thirty-two Ammonite genera have up to the present time been recognised in the Alpine Trias, of which thirteen are peculiar to the northern life-province, five are restricted to the southern life-province, while fourteen are common to both. Although Dr. Mojsisovics's work has, up to the present time, been confined to the Cephalopoda, yet we anticipate results of scarcely less interest when he arrives at the examination of the Gasteropoda and the other classes of fossils obtained from the Alpine Trias.

The work before us is in great part the result of the investigation of the Austrian Geological Survey, carried on under the direction of Franz von Hauer, and much of the detailed examination of certain of the districts described was accomplished by two of the author's former colleagues Dr. Hoernes and Dr. Doelter; the account of the volcanic and granitic rocks is indeed almost entirely supplied by the latter geologist, who is so well known for his skill in micropetrographic researches. The most important part of the work, however, is that which is devoted to the description of the several Mesozoic formations of this Alpine area, and to a discussion of the important facts concerning the former physical geography of the region, and the distribution of life-forms within it—questions which the author is so well qualified by his long study of the subject to treat of.

As a consequence of the representations made to the Academy of Sciences of Vienna by von Hauer, Suess, and Hochstetter, a special grant of money was made to aid the author in the publication of this valuable monograph, and no expense has been spared to make both the book itself and the atlas which accompanies it, of the greatest possible value. In these respects the work resembles the publications of the American Geological Surveys much more than those of our own country.

The atlas contains six sheets, comprising an area of about 3,000 square miles, and is constructed on a scale of $\frac{1}{75000}$, or about $\frac{7}{8}$ of an inch to an English mile. The foundation of the map is, for the southern or Italian part, the old general map of the Austro-Hungarian Empire on the same scale, and for the Tyrolese area the new military map of Austria on a scale of $\frac{1}{25000}$, which has been reduced by photography. The geological colouring is admirably printed, and although between forty and fifty different tints have been employed to indicate the numerous subdivisions adopted by the author, this is accomplished without creating confusion, or obscuring the topographical details of the map. The district comprised in it includes the country lying between the Adige and the Piave, from Toblach, on the north, to Feltre, on the south, the larger portion of which is included in the Austrian Tyrol, but a considerable area in the south-west now belongs to the Italian monarchy.

The memoir itself is illustrated by thirty reproductions of photographs taken either by the author himself or by Egger of Lintz, the points of view in the latter cases having been chosen by Dr. Hoernes. These views give an excellent idea of the remarkable natural features presented by this very interesting district, the now famous "Dolomite Mountains." In addition to these views and the very numerous woodcut sections, there is also a series of maps illustrating the areas of the old coral reefs and the lines of disturbance traversing the district.

The first or introductory part of the memoir, consisting of four chapters, gives a general sketch of the geology of the district and of the physical features of the Southern Tyrol. The second part (Chapters V.–XV.) is devoted to a detailed description of the geological structure of the several districts, while the third and concluding part (Chapters XVI. and XVII.) deal with theoretical questions of great interest to geologists at the present time, namely, the reef-theory of von Richthofen and the origin and mode of formation of mountain chains. We regret

that the space at our disposal will not permit of our following the author in these interesting discussions, and we can only, in conclusion, heartily recommend the work to the traveller as being admirably adapted to guide him in investigating the geology of a district of extreme interest and great complexity, and to the student at home as containing numerous facts and suggestions worthy of the most thoughtful consideration. J. W. J.

HEALTH PRIMERS

Health Primers. Edited by J. Langdon Down, M.D., F.R.C.P., Henry Power, M.B., F.R.C.S., J. Mortimer-Granville, M.D., John Tweedy, F.R.C.S. (London: Hardwicke and Bogue.)

THE proverb that a little knowledge is a dangerous thing is especially true in regard to matters connected with health, and it might therefore be supposed that the issue of a series of health primers was a thing to be deprecated, as likely to do harm. But a little reflection will show that this series is intended, not to impart a little knowledge, but to replace the knowledge, not merely little, but confused and inaccurate, which every man supposes himself to possess, by something more definite and exact. Every one fancies that he knows the appearances of health and disease, and that he is able to decide upon the condition of those whom he daily meets. Every man supposes himself able to pronounce that such and such a house cannot be healthy, and believes that he is quite capable of judging for himself how much exercise he ought to take, whether he should or should not use a cold bath in the morning, and what is the proper allowance of beer, wine, or spirits, either for himself or for his neighbours. Now, despite the confidence with which most men will pronounce an opinion on all these subjects, the data on which they would found that opinion would really be very slight, and their knowledge of the subject probably very imperfect and inaccurate, and, consequently, the conclusions at which they would arrive would most likely be erroneous. It is just on such subjects as those we have mentioned that the books of this series afford accurate information. The first of them, "On Premature Death, its Promotion and Prevention," is of a less popular character than the others, and has, we think, suffered in consequence of its author not having seen the contents of the other primers. While the material it contains is very valuable, it deals, we think, too much with statistics and too little with the causes of premature death which are under the control of the individual, although occasionally, however, it gives these also, as at p. 46, where ventilation in a hospital is said to have put a stop to the convulsions from which the children died in great numbers, and reduced the mortality to $\frac{1}{28}$ of its previous amount. But on the other hand, while we learn that 6 per cent. of the total mortality from all causes is due to diseases of the heart, the writer says nothing of the dangers incurred in running after an omnibus or in trying to catch a train.

The primer on "Personal Appearance in Health and Disease" includes the changes which the body may undergo in the form and size of its bony framework, fatty layer, and internal organs, as well as external colour. These are given shortly and well, though the alterations produced artificially by tight-lacing and high-heeled and tight boots might have been still more strongly insisted upon and emphasised by woodcuts showing their results.

"The House and its Surroundings" is clearly written, and contains a great deal of very useful information. By its aid the householder should be able to know where to look for defects in drainage, ventilation, water supply, &c., and thus to avoid many sources of disease, although we think that the dangers of arsenical wall-papers ought perhaps to have been more strongly insisted upon.

"Baths and Bathing" discusses the physiological action, varieties, and uses of baths and bathing localities, both at home and abroad. It is written in a very readable style, and contains both advice as to the use of baths and cautions in regard to their abuse. The author warns against the too heroic use of a morning tub, but forgets to state how very much the chilliness which it brings on in persons of languid circulation may be prevented by using a bath sheet instead of a towel, so that the whole body shall be covered during drying, and not chilled by the exposure of the wet skin to the cold air.

"Exercise and Training" gives a general account of the changes produced in the body by muscular exertion, of the food required, the general *régime* to be pursued, and the dangers to be avoided. It is evidently written by one who is familiar with the subject of which he is treating.

"Alcohol, its Use and Abuse," deals with a very difficult subject, and does it well. The author is not prejudiced either for or against alcohol, and maintains that because ninety-nine persons out of a hundred misuse it, it is none the less true that it has a right use, this use being sometimes to check the current of thought and care, as well as to stimulate digestion and circulation, although in perfect health its use is unnecessary.

The purpose which these primers are intended to serve is a very important one, and we think that they are well calculated to serve their purpose. We have pointed out one or two things in which we think they might be improved in future editions, but on the whole they are well and carefully done, giving accurate information in a condensed yet popular form. LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts. No notice is taken of anonymous communications.*]

[*The Editor urgently requests correspondents to keep their letters as short as possible. The pressure on his space is so great that it is impossible otherwise to ensure the appearance even of communications containing interesting and novel facts.*]

The Mechanical Theory of Earth-Heat

NOTICING the assertion made in NATURE, vol. xx. p. 22, in reference to Prof. Church's article in *Silliman's Journal* on the Comstock Lode, that "the rock in the lower levels seems to have a pretty uniform temperature of 130° F.," and remembering what Prof. G. F. Barker, of the University of Pennsylvania, told me, that on a recent visit to those mines he found that there was no uniform temperature, but on the contrary, the most remarkable differences, some of the higher levels being much hotter than some of the lower levels—so that he came to two conclusions:—(1) That the heat was a hot water heat, and (2) that the hot waters were heated mechanically by those continuous movements of the country, so plainly shown both in the mines and at the surface;—it occurs to me to ask the following question:—

Has any one, in the discussion of Mallet's hypothesis, thought of bringing its probability to such a test as the volatilisation of the hydrocarbons of coal-beds in a highly plicated region like Belgium?

It is a remarkable fact, and one which seems to me inconsistent with the mechanical theory of earth-heat, that of two extensive regions, Belgium and Eastern Pennsylvania, equally and excessively disturbed by complications, all the coal-beds of the one are anthracite, and all those of the other are bituminous.

Again, of two regions equally undisturbed, Western Pennsylvania and Arkansas, the horizontal coal-beds of the one are bituminous and of the other anthracite.

Surely, if movements of stratum on stratum produce all the needful heat, *no* plicated coal-beds should escape being converted to anthracite; and I should much like to hear from English geologists how this argument is to be met. My own explanation of the origin of anthracite is not worth much, but it is the best I know. I refer such origin to three causes acting in conjunction—(1) Heat due to superposed (now wholly or partially removed) Permian and later formations; (2) Greater proportion of sands in the anthracite and of clays in the bituminous coal-measures; and (3) Plication and fracture, permitting the exit of volatilised hydrocarbons into the atmosphere.

American Philosophical Society, Philadelphia, May 22 — J. P. LESLEY

Evolution Old and New

MR. A. R. WALLACE writes, in NATURE, vol. xx. p. 143, that, according to the theory which I support, Australian (and more especially Queensland) sheep should show a tendency to grow a scantier and thinner fleece than their English ancestors. "If Mr. Butler," he continues, "could adduce on good authority such a fact as this, he would have some evidence in his favour, instead of which he can only make suppositions."

I never was in Australia, but had some years' experience of sheep-farming in New Zealand. It was generally believed, in my time, that fleeces soon became short and hairy in Queensland, and even in the more northern part of New South Wales. You must, however, have many readers who could tell us what the facts are. May I hope that you will kindly insert this, so as to get the matter settled by eliciting information from a competent authority? I am speaking, of course, of sheep that are left to the effect of the climate, without being frequently crossed with rams from colder countries. Do the fleeces of such sheep deteriorate in Queensland? — S. BUTLER

June 12

The River Elbe

IN NATURE, vol. xiv. p. 498, some particulars are given of measurements made in 1871 and 1872 of the water flowing past in the Elbe at the boundary between Saxony and Bohemia. The river basin in Bohemia above this point is stated at 880 square miles, which is evidently wrong, as the annual discharge of 6,179,000,000 cubic metres (218,223,743,000 cubic feet) would give a depth of 107·64 inches run off the ground. Measuring roughly on the map, the area of Bohemia—which, apparently, all drains into the Elbe—is 20,000 English square miles. If, on the other hand, the measurements of the river water and the solids in solution and suspension are correctly given, and the river basin is 20,000 square miles, the rainfall must have been exceptionally low at the time the measurements were taken, as the figures represent only about half that of the mean annual flow off the ground in the Danube basin, which is 9·06 inches. Perhaps the writer of the notice will be able to find out how these discrepancies occur. I may add that, taking the figures as given in NATURE, 607 tons per square mile per annum are removed in solution in the Elbe water. From a district composed mostly of silurian rocks, this is manifestly absurd. According to my calculations,[1] 72·7 tons per square mile are annually removed in solution in the Danube water.

Blundellsands, June 17 — T. MELLARD READE

Electric Light

IN NATURE, vol. xx. p. 110, an account is given of Sir William Thomson's evidence on the electric light. It is stated "that one horse-power had produced 1,200 candles of actual visible electric light, whereas one horse-power of energy would only produce 12-candle gas-light." In the report of Sir J. W. Bazalgette and Mr. Keates to the Board of Works, which is probably the best report we have yet had on the subject, as to the actual cost of the electric light on the Thames Embankment, it is stated that the cost of the electric light was 5·75*d.* per hour, whereas the cost of the gas required to produce a light equal to the electric light as regards illuminating power, in an opal globe, was 2·00*d.*, and in a frosted globe 3·50*d.* per hour. Would any of your numerous readers be kind enough to give me some idea of the qualifications to be appended to the above statements, which will reduce the long odds calculated by Thomson of 100 to 1 in favour of the electric light, to the odds of 2 to 1 against it as found in actual practice? In conclusion may I venture humbly to suggest that such conflicting statements as the above, if unexplained, are apt to bring the dicta of scientific men into disrepute with the thinking portion of the general public. — F. J. M. P.

The Climbing Perch

THE aquarium of the Zoological Society's Gardens in Regent's Park has lately received a contribution of five specimens of the "Climbing Perch" (*Anabas scandens*). They were very kindly obtained for me by my friend, Mr. A. Ferguson, of Colombo, Ceylon, and were brought home in excellent condition by my brother, Mr. A. F. Dobson. Mr. Ferguson (who is so well known in Ceylon as a naturalist of great experience) kept the fish for some months in an aquarium, and trained them to take chopped meat from the hand, so that they were in the best possible condition for their long journey.

The first specimens of this fish which arrived alive in Europe were sent by me from Calcutta in 1872 to the Royal Zoological Gardens in the Phœnix Park in Dublin, where they lived for a considerable time.

I have described (P. Z. S., 1874), in my paper "On the Respiration of Indian Fresh-water Fishes," the manner in which *Anabas scandens* takes in, and rejects again, the atmospheric air, and on a visit to the aquarium in the Gardens the peculiar conduct of these fishes when respiring may be witnessed by any one.

Mr. Ferguson informs me that he has specimens of some species of *Ophiocephali* and the remarkable *Arius bakeri*, which carries its young in its mouth, in training, and I hope soon to have an opportunity of having them safely carried to England.

Netley, June 14 — G. E. DOBSON

Oxygenated Rain

ON Thursday, June 12, at half-past eleven in the morning, a remarkable shower of rain fell over London, which might almost be described as "effervescing;" the drops whilst falling appeared to be colourless and perfectly transparent, but on striking against any solid surface they became milky, and on close examination it was evident that this cloudy appearance was caused by a number of very minute air-bubbles, which rapidly increased in size, and then burst. From the bleaching power which this rain appeared to have, I am led to believe that there was nascent oxygen in the gas thus evolved. Those who traverse the streets of London in the early morning may now and then observe the red colour of all bright iron-work in the pavement, such as coal-plates, &c., due to the oxidising influence of a thunder-shower in the night; this effect does not follow every thunder-shower, but seems to indicate a peculiar atmospheric condition. Have any memoranda on this subject been recorded? — EDWARD SOLLY

WILLIAM FROUDE[1]

LAST week we called attention to Mr. Froude's discoveries of those laws of motion of floating bodies, upon which the behaviour and safety of a ship passively floating among sea waves depends. We now purpose giving a brief outline of his researches in another branch of hydrodynamics by which he arrived at a true appreciation of the nature and amount of the resistance opposed by water to the passage of a body like a ship through it. In connection with the resistance of ships, the subject of marine propulsion, which Mr. Froude has also done much

[1] Continued from p. 150

to elucidate and bring within the grasp of scientific treatment, will naturally find a place.

The resistance of ships and the speeds that could be relied upon in practice by the application of a given amount of force has always been a fruitful source of trouble to naval architects and engineers. The various formulæ that have been used for calculating the speed of ships, and which were based upon what were supposed to be the true laws of resistance, have always been uncertain and unreliable in their application. Mr. Froude has shown that this is because the approved formulæ "were not only wrong in detail, but that the supposed cause of resistance, with which alone they professed to be dealing, was in reality no cause at all; and that the real cause of resistance, whatever it might be, was entirely left out."

This supposed cause of resistance, which "was in reality no cause at all," was alleged to be due to the inertia of water, and the necessity for pushing those particles out of the way which offer an obstruction to the progress of a ship through the fluid. Thus it seems that there must be an excess of pressure upon the fore part of a ship when she is excavating or pushing water out of her way; and a diminution of pressure or partial vacuum on the after part when she is travelling away from the particles which press against her. There would therefore be a total resistance caused by excess of pressure forward and deficiency of pressure aft. As this resistance would depend upon the volume of water that would have to be pushed out of the ship's way; it appeared obvious that it must be measured by the area of the ship's cross section.

These considerations were expressed in the following formulæ, which have been those chiefly used by shipbuilders till the last few years, and have been preferred by the Admiralty to any other down to the time when they placed the determination of the speeds of ships in Mr. Froude's hands. The formulæ are—

$$V^3 = \frac{C_1 A}{P} \text{ or } = \frac{C_2 D^{\frac{2}{3}}}{P}.$$

when $V =$ the speed of the ship, $A =$ the area of the greatest immersed cross-section, or "the area of the ship's way," $D =$ the ship's displacement, $P =$ a measure of the propulsive force, which stands for the indicated horse-power of the engines, and C_1 and C_2 are constants obtained from the observed performances of other ships. These are only formulæ of comparison between different ships, and were always regarded as being strictly applicable only to the comparison of ships of similar form. They are obviously based upon the assumption that the resistance is as the square of the speed and the area of the vessel's way, or of the canal she may be supposed to cut through the water in going from place to place. This is strictly the assumption in the first formula, which includes the exact area of the immersed cross-section of the vessel; but in the second formula, though the character of the assumption is the same, the area is corrected to represent the supposed equivalent cross-section for variations of displacement.

These formulæ gave fairly accurate results when applied to vessels of good form which were similar to those from which the constants were derived, and when the speeds were low. It was known, however, that the speeds of vessels of exceptional form and dimensions could not be thus calculated, and that in all ships the resistance increased at a faster rate than the square of the speed beyond certain limits, which limits were different in different ships. The development of the true laws of fluid motion, or the doctrine of stream-lines, by Prof. Stokes, Prof. Rankine, Sir William Thomson, and others enabled the real causes of a ship's resistance to be ascertained. It was then seen to be quite wrong to suppose that the work done in propelling a ship is in any degree analogous to excavating a canal, and spreading the water she successively displaces over the surface.

The stream-line theory showed that the reactions which the inertia of the fluid would cause against the surface of a ship moving through it arranged themselves quite differently to what had formerly been supposed, and that such methods of estimating their total effect—which was supposed to constitute the resistance—as we have referred to were fundamentally wrong. Indeed it shows that there is nothing in nature to correspond with the old idea ot head resistance, because, according to the stream-line theory, a submerged body such as a fish, or a torpedo, once put in motion in a frictionless fluid would continue to travel with an uniform speed, and experience no resistance. Certain particles of fluid would have to be set in motion to enable such a body to pass them, but this would be done in such a way as to cause no resistance in the direction of motion. The backward forces acting upon the body on some parts of its surface would be balanced by the forward forces acting upon other parts, and the inertia of the fluid would propel it forward at some points with an equal force to that opposed in resistance at other points.

Mr. Froude showed most clearly and conclusively how this paradoxical result came about in his presidential address to the mechanical section of the British Association delivered at Bristol in August, 1875,[1] and also in a lecture delivered at the Royal Institution on May 12, 1876. He proves that in a perfect or frictionless fluid there is no power by which any endways resistance can be caused to the passage of a submerged body moving uniformly through it. Substituting for the submerged body moving through a stationary ocean of fluid the plainly equivalent conception of a stationary submerged body surrounded by a moving ocean of fluid, Mr. Froude points out that at a sufficient distance ahead of the body the ocean is flowing steadily on, in what may be imagined to be a collection of streams of any size and cross-section we please. All these streams must have the same direction, velocity of flow, and pressure. In order to get past the body these streams must alter their direction and velocity, settling themselves into courses which will be determined by the various reactions they exert upon each other and upon the surface of the body—"yet ultimately and through the reverse operation of corresponding forces, they settle themselves into their original direction and original velocity. Now the sole cause of the original departure of each and all of these streams from, and of their ultimate return to, their original direction and velocity, is the submerged stationary body; consequently the body must receive the sum total of the forces necessary to thus affect the streams. Conversely this sum total of force is the only force which the passage of the fluid is capable of administering to the body. But we know that to cause a single stream, and therefore also to cause any combination or system of streams to follow any courses changing at various points both in direction and velocity, requires the application of forces the sum total of which in a longitudinal direction is *nil*, provided that the end of each stream has the same direction and velocity as the beginning. Therefore the sum total of the forces (in other words, the only force) brought to bear upon the body by the motion of the fluid in the direction of its flow is *nil*."

A frictionless fluid would, therefore, offer no resistance to a submerged body moving through it. Mr. Froude next introduced the consideration of friction, which brings two causes of resistance into play. First, there is the friction proper which is due to the drag of the particles of water upon the surface of a body as it moves through it, and which is governed in amount by the area of the surface, and also by its nature, whether smooth or otherwise; and secondly, there is the defect of pressure at the rear end of the body caused by the stream, line motions being somewhat impeded by friction between the

[1] Published in NATURE of November 18, December 2, 16, and 30, 1875.

particles. This is very obvious in blunt-ended bodies where the stream-lines, instead of closing in round the rear end and exerting their due pressure in the direction of motion, force themselves into eddies and whirls. Mr. Froude calls this element of resistance "eddy-making resistance." It is imperceptible in ships of fairly easy shape, but is of large amounts in ships with very full sterns. He shows that a submerged body of good easy shape would practically experience no resistance except that due to surface friction, and the amount of resistance would be practically the same as that of a thin plane moving edgeways, which has the same area of wetted surface.

Mr. Froude next shows that when we come to the case of a ship or a body travelling at the surface, a new cause of resistance is introduced, due to the system of surface-waves which is generated. The variation of pressure in the stream-lines formed at the sides of a ship relieves itself at the surface by raising or lowering the level, and thus a bow and stern wave with a depression amidships are formed and carried along as the ship progresses. These waves once made, however, require little force for their maintenance, so long as they are not swollen to abnormal dimensions by the increased wave-making tendency a ship possesses at high speeds. Other systems of waves are also generated and driven off from the ship in various directions by features of form that interfere with the natural courses of the stream-lines. There are, therefore, three great causes of resistance to a ship: 1, surface friction; 2, eddy making; and 3, wave genesis. Mr. Froude shows that the first, viz., surface friction, practically agrees with the resistance experienced by a plane of the same wetted surface drawn longitudinally through the water at high speeds, and that the eddy-making resistance is practically nothing in well-formed ships having fine ends; but that the wave-making resistance is so indeterminate in its character as to be incapable at present of direct calculation.

Mr. Froude estimated the total amount of a ship's resistance by means of careful experiments with a model made to her exact form. The method of doing this with accuracy is one of Mr. Froude's greatest and most useful discoveries. Model experiments of this nature that had previously been made were so misleading that it was generally believed to be impossible to infer the resistance of a ship from that of a small scale model. Mr. Froude saw, however, that all three elements of resistance followed the same laws in similar bodies, whatever the differences of size might be, and that all that was required to make experiments with models reliable was to discover the true scale of comparison. This scale, or law of comparison, he discovered, and stated as follows:—"If the ship be D times the 'dimension' (as it is termed) of the model, and if at the speeds V_1, V_2, V_3 .... the measured resistances of the model are R_1, R_2, R_3 ...., then for speeds $\sqrt{D}\,V_1$, $\sqrt{D}\,V_2$, $\sqrt{D}\,V_3$ .... of the ship the resistances will be $D^3 R_1$, $D^3 R_2$, $D^3 R_3$ .... To the speeds of model and ship thus related it is convenient to apply the term 'corresponding speeds'"; the special feature of this "correspondence" being the fact that at such speeds precisely similar wave systems are generated by ship and model.

Mr. Froude tried in 1867 a large number of resistance experiments with models of various forms and dimensions, by towing them from the ends of 10-foot scale beams, connected with self-recording dynamometric apparatus, and mounted on booms projecting sideways from the bow of a steam-launch. Some of the results were in glaring contravention to the ordinary principles current at the time, and Mr. Froude invited Mr. E. J. Reed, C.B., M.P., who was then Chief Constructor of the Navy, to witness the experiments. Mr. Reed saw the necessity for fresh investigation, and by his recommendation a further series of experiments was sanctioned by the Admiralty.

These experiments were brought into further prominence by the action which was taken upon a report of a committee of the British Association in 1869, upon the stability, propulsion, and sea-going qualities of ships. On the recommendation of this committee an application was made to the Government for carrying out experiments upon resistance with actual ships of considerable size. Mr. Froude, who was a member of the committee, dissented from this report on the ground that the various elements of resistance and the laws of their operation "could be discovered with far greater facility and completeness by small-scale than by full-size experiments." The Admiralty requested Mr. Froude to conduct an extensive series of experiments with models; this he undertook and continued up to the time of his death with the greatest skill and success. The results thus obtained furnished data for determining the resistance of ships of various forms and dimensions to a considerable degree of exactness, and also showed what circumstances were favourable to speed and what were not.

This subject had an important bearing upon some of the inquiries instituted by the Committee on Designs for Ships of War, in 1871, and they requested the Admiralty to determine experimentally the actual resistance of a full-sized ship. The Admiralty accordingly ordered the requisite experiments to be made upon H.M.S. *Greyhound*, a vessel of about 1,150 tons displacement. The experiments were made under Mr. Froude's superintendence. The *Greyhound* was towed by H.M.S. *Active*, and the resistance at various speeds recorded by means of a delicate dynamometric apparatus. She was towed from the end of a long outrigged boom, so as to be clear of the wake of disturbance, and every possible precaution was adopted to eliminate all the various sources of error. The experiments verified to a remarkable degree the law of comparison propounded by Mr. Froude as governing the relation between ships and their models, and perfectly justified the reliance he had placed upon his method of investigating the effects of variation of form by trials with varied models, a method which, as Mr. Froude afterwards remarked, "if trustworthy, is equally serviceable for testing abstract formulæ, or for feeling the way towards perfection by a strictly inductive process."

The value of Mr. Froude's method of calculating the speeds of ships from those of their models, became so obvious, that the Admiralty discarded their old methods, and referred their designs to Mr. Froude for his estimate of their speeds. Besides the elaborate series of experiments which Mr. Froude has had in course of procedure at his experimental tank at Torquay for determining the best form and proportion for various classes of ships, designed for various speeds, most of the new Admiralty designs have been experimented upon and modified forms suggested where improvement could be made. The results of his work, and especially of the recent trials of H.M.S. *Iris*, whose lines were determined by Mr. Froude for the high speed of 17½ knots—have borne striking testimony to the correctness of his work.

Mr. Froude has, however, done much more than show how to calculate with accuracy the speed of a ship from that of her model. He has shown how the various elements of resistance act upon a ship at given speeds, and the laws upon which they depend. In well-formed steamers the resistance at low speeds consists almost entirely of surface-friction. This was the case in H.M.S. *Greyhound* at a speed of eight knots. If a curve of total resistance be made from experiments with a ship or model, and a curve of frictional resistance be also placed on the same base line, they will be found almost identical at their low speeds. The resistance due to the formation of eddies is so small in well formed ships as to be hardly appreciable. When a ship of tolerably fine lines is moving at a moderate speed, the whole resistance, therefore, consists of surface-friction. As the speed

is increased, the curve of total resistance ascends more or less above the curve of frictional resistance, and in some cases departs very largely from it. The rate of departure as the speed increases differs largely in different ships, and in vessels of the same section, but of different lengths. Mr. Froude conducted a series of experiments upon models of the same cross section and form of ends, but with the length successively increased by lengths of parallel middle body. These models corresponded to ships of lengths varying from 160 feet to 480 feet in total length. At the lower speeds, up to about eleven knots, the resistance increased by about equal increments with equal increments of length of the ship, but at higher speeds this harmony disappeared. At thirteen knots the 200-feet ship makes considerably more resistance than the 240-feet ship, and at $14\frac{1}{2}$ knots the 200-feet ship makes almost as much resistance as a 360-feet ship of 2,275 tons more displacement. Similar anomalies appear in the comparison between other ships. These were shown by Mr. Froude to be due to the influence of wave-making resistance, and to depend upon the positions occupied with reference to the stern of the ship by the waves generated by the bow. The practical point involved is that a ship may sometimes be lengthened considerably without any loss of speed for the same application of power; whereas if the conditions favourable to this are not complied with, she may, on the other hand, require a disproportionate increase of power to keep up her speed. Mr. Froude has shown how the most favourable conditions can be realised in this respect.

These investigations into the resistance experienced by ships at different speeds have thrown great light upon that long-disputed problem in naval architecture, "the form of least resistance," and has gone far to enable shipbuilders to arrive at the best form and proportions for the speed required, which is compatible with other requirements. Economically such a discovery is of great value in enabling more work to be done in steamship propulsion for a given engine-power and expenditure of fuel.

Mr. Froude's dynamometric experiments upon the resistance of the *Greyhound*, and some results of the steam trial performances of other ships, showed him that the actual resistance of a ship was much less than had been generally supposed. At eight knots speed the pull upon the tow-rope of the *Greyhound*—a ship of 1,150 tons displacement—was only $2\frac{1}{2}$ tons, and at ten knots $4\frac{3}{4}$ tons. This was so very much below the thrust the screw was supposed to exert when driving the ship at those speeds, that Mr. Froude set to work to investigate the relation between the indicated horse-power of marine engines as represented by the work done by the steam in the cylinders, and the power that is usefully employed in propelling the ship. He found, as the result of many experiments, that in ordinary ships at full speed the former is 2·7 times the latter, or that the effective horse-power, as given out by the thrust of the screw, is only $37\frac{1}{2}$ per cent. of the power indicated in the cylinders.

Mr. Froude decomposed the indicated horse-power of the engine into its constituent parts, and approximately quantified each element as follows:—

1. The useful thrust or ship's true resistance = E.H.P. or the effective horse-power.

2. The augmentation of the ship's resistance by the induced negative pressure under the stern consequent on the thrust of the screw. Mr. Froude often called attention to this cause of resistance, and showed that it might be greatly reduced by placing the screw a short distance abaft its usual position. He ascertained by experiment that with ships of ordinary form the resistance is increased on account of the action of the screw by about 40 or 50 per cent. of her nett resistance. The power required for this therefore = 0·4 E.H.P.

3. The friction of the screw blades in passing through the water, which was found to be = 0·1 E.H.P.

4. The constant friction due to dead weight and the tightness of the moving parts. This is at all speeds about one-seventh of the total load of the engines when working at full speed and pressure. It is therefore = 0·143 I.H.P., I.H.P. being the total indicated horse-power.

5. Friction due to working load of engine. This is also = 0·143 I.H.P.

6. Air-pump resistance. This is approximately equal to 0·075 I.H.P.

Summing up these several elements it will be found that the effective horse-power at full speed is little more than $37\frac{1}{2}$ per cent. of the indicated horse-power.

This analysis of the manner in which the power of the engines is employed is very valuable in indicating the manner in which loss of power may be treated in detail, and also in furnishing a reliable means of comparison between the efficiency of different engines. It will take time to come into general use, but cannot fail to do so as it becomes understood and appreciated. Already some of our most intelligent shipbuilders, such as Mr. Denny of Dumbarton, and Mr. Inglis of Glasgow, have applied Mr. Froude's theories to practice, and are working upon the improved methods he has laid down both for increasing the effect in the propulsive power of the engines, and in diminishing a ship's nett resistance.

The general adoption of these theories will be a great boon to science, as well as a practical benefit, in point of economy to the ship-builder and ship-owner. Science will benefit by having the performances of ships recorded in such a manner as will be available for correcting the present theories, and throwing light upon such laws of hydrodynamics as are yet undiscovered or but imperfectly understood.

One great difficulty in making any scientific use of steamship performances has arisen from the absence of any method of determining the power delivered to the screw. All that was ever ascertained was the power indicated in the cylinders, and, as we have seen, this was found to be enormously in excess of the effective power employed in propulsion. As the problems of resistance and propulsion can only be accurately treated by dealing with the thrust exerted by the screw, it became desirable to have some means of measuring this in actual ships. Mr. Froude, who had frequently pointed this out, was asked by the Admiralty to devise a dynamometer that would measure the power delivered at the end of the screw shaft in large marine engines. The problem was a most difficult one, but Mr. Froude solved it in a most complete and admirable manner. He described the instrument he had invented in a paper read before the Institution of Mechanical Engineers in July, 1877, and a description of it is given in NATURE, August 2, 1877. It fulfils all the conditions of giving a true indication of the power, being simple, compact, and easy of application. A machine for dealing with an engine of 2,000 I.H.P. is all included in the circumference of a circle of three feet radius, and as its power increases as the fifth power of its linear dimensions, it can be applied to any size of engine without becoming unduly large.

We have glanced hastily over some of Mr. Froude's achievements in science, but it is impossible within the limits at our disposal to do more than glance at them, or even to refer to many. He was a scientific worker of the best and rarest type, and was constantly employed in perfecting the details of his theories or striking out new lines of thought. He was a master of the delicate art of experimental and theoretical investigation, and a study of his work would show many perfect examples of the manner in which, by induction, a knowledge of the causes of phenomena may be arrived at. Being an excellent mechanic, and a most conscientious and ingenious experimentalist, Mr. Froude put all his theories and

hypotheses to the most crucial and varied practical tests, and conclusively proved their truth, or determined the limits of error involved by them. He had the power of arranging almost intuitively simple experiments for qualitatively testing the value of an idea, and his mathematical knowledge and power of close and accurate reasoning enabled him to work out the quantitative results of a difficult problem with great facility. His experimental tank at Torquay, with all the delicate and interesting contrivances in connection with it for measuring and recording the behaviour of models in rolling or their resistance to motion through the water is a marvel of philosophical arrangement and practical skill. Mr. Froude's published papers include but a small portion, we believe, of his work. It would be a worthy tribute to his memory, and a great boon to science and to the shipping interests of the country if the result of his researches could be published in a complete form, and thus made readily accessible.

Mr. Froude had not much encouragement during the early days of his investigations upon these subjects. The first to appreciate their value were the late Prof. Rankine and Mr. Crossland, one of the constructors of the Navy. Mr. Crossland was one of the first to see that Mr. Froude, in his first paper on the Rolling of Ships, read before the Institution of Naval Architects in 1861, had indicated the true laws of rolling motion, and in the following year he contributed an original paper upon the same subject. Mr. Reed was the first to apply the principles enunciated by Mr. Froude to the construction of ships; and did so with great ability and success. Canon Moseley, Dr. Woolley, and others did not see, however, for a considerable time, that Mr. Froude had made a great stride in advance of previous knowledge, and had really discovered the means that had long been wanted of arriving at a due comprehension of the dynamical laws which govern a ship's behaviour at sea. Mr. Froude's lucid and painstaking explanation of his theory and replies to the objection of Dr. Woolley and others produced in due time their full effect, and in the course of a very few years all who were capable of understanding the arguments upon which the theory was based were thoroughly convinced that Mr. Froude's method and its results were sound, and were such as could alone lead to improvement in this branch of science.

Mr. Froude's scientific reputation and the value of his work now rest upon a solid foundation. His discoveries have revolutionised whole theories of hydrodynamics, and have stood the test of practical application. He has received various honorary distinctions, such as the degree of LL.D. from the University of Glasgow, and the Royal Medal of the Royal Society; but his greatest distinction, and that with which his name will always be associated, is that, in an age when science is fashionable and many of its professors look more to the show than the substance, Mr. Froude devoted his energies to a long and unwearied search after truth in a department of science that few knew anything about, and that could have no interest for the many, and he looked only to success for his reward. Happily, in this sense he was bountifully rewarded, and has left, both in the subject-matter of his researches and the example he set in pursuing them, a legacy to those who follow after which should stimulate them to work with all their might, with the one object of endeavouring also to attain unto truth and to be worthy of being admitted within the veil of the temple of nature.

KARL KOCH

THERE are very few even among professed botanists, who avail themselves to any thing like the extent they might do of the teachings of a garden. And yet for the study of the life-history of plants and for the due estimation of their precise degree of relationship one to the other a garden offers in some ways—in many ways—unrivalled opportunities.

Karl Koch, whose death we lately recorded, was one of the few who had a right appreciation of the resources of a garden and who knew how to turn them to account. His tall, attenuated form and keen eye were to be observed at most of the International Botanical and Horticultural Congresses which have been held in various continental cities and in London in 1866. Everywhere, by horticulturists as by botanists, his claims to high rank among his fellows and his title to respect and even affection for his personal qualities were acknowledged, so that it became a pain to those who saw him recently to notice his gradually failing powers and to see how the old spirit was curbed and checked by impaired physical health.

Karl Koch was born in Weimar in June, 1809. In that little capital he came in contact, as a youth, with Goethe, and it was partly owing to his influence and advice that Koch made his visits to the Caucasus and various parts of Asia Minor. Shortly after he had completed his studies in medicine and natural history at Jena and at Würzburg he set out on his travels, his special objects being the investigation of the vegetation and an inquiry into the original sources of our cultivated fruit-trees. After two years' research he suffered so severely from the effects of sunstroke on Mount Ararat that he was obliged to return to Jena, but in 1843 he set out a second time for the East. Of his first journey an account was published in 1842, under the title of "Travels through Russia," of his second, in 1845, under that of "Wanderings in the East." A general account of his travels may be found in the *Linnæa* for 1848, in which publication also may be found catalogues and descriptive lists of the plants collected by him, together with remarks on the geographical distribution of plants in the Caucasus, &c. On his return from this second expedition he became assistant-director of the Botanic Garden at Berlin, secretary of the Prussian Horticultural Society, and, a few years later, Professor of Botany in the University.

His position at Berlin gave him exceptional facilities for studying cultivated plants, and, accordingly, much of his botanical work consisted of monographs of Arads, Bromeliads, Agaves, and other plants, necessarily imperfectly preserved in herbaria. Many such monographs are scattered through the *Wochenschrift* of the Berlin Horticultural Society, and which was for many years edited by him. As a pomologist also he held no mean position, but the most interesting and valuable part of his labours, so far as this branch is concerned, are those relating to the origin of cultivated fruit trees, a subject intimately connected with the history and migrations of our own race.

His *magnum opus*, however, is his "Dendrology"—a scientific description of the trees and shrubs cultivated in the forests and gardens of central Europe, a work for which his travels had well prepared him. For the purpose of compiling this volume Koch visited almost every country in Europe. All the great nurseries of the Continent and of our country were also inspected by him with the object of study or of securing specimens.

Despite small defects of method Koch's descriptions are excellent and characteristic, so much so, that it is a great pity that his work has not been translated into English. The technical details of his subject are enlivened by short biographical notices of the botanists and horticulturists whose names are the most prominently associated with the department of botany, of which his work treats. The reader of these interesting notes to an otherwise necessarily dry technical book will have no difficulty in understanding the estimation in which Koch's popular lectures on trees and on fruit trees in particular were held by the Berlin public.

In private life Koch was beloved for his uprightness, loyalty, and warm-hearted devotion to his friends.

THE ELECTRIC DISCHARGE WITH THE CHLORIDE OF SILVER BATTERY

MESSRS. De La Rue and Müller, in the second part of the researches which they have carried on during three and a half years, have contributed facts of the highest value towards the solution of the problem presented by the beautiful phenomenon of stratification produced by electric discharges in vacuum tubes. The following are some of the more important results of these experiments as described by the authors.[1]

These phenomena, first noticed by M. Abria in 1843, were independently re-observed by Mr. (now Sir William) Grove in 1852, and have since engaged the attention of many physicists. The late Mr. Gassiott, working at first with an induction coil, but more recently on the same lines as the voltaic batteries of high potential,[2] published results of great interest; while, on the other hand, Mr. W. Spottiswoode is still pursuing with great acumen and originality a similar investigation, both with the induction coil and the Holtz machine, with which he has recently used condensers of great capacity.

Throughout our labours we have felt so strongly the necessity of obtaining numerical results as data for the foundation of a theory, that we have not hesitated to risk much in this cause. By the fusion of terminals, or the sudden discharge of the condenser, we have lost a vast number of very beautiful tubes; but gradually by the adoption of various devices, and by the employment of instruments specially constructed and insulated to suit the high potentials we deal with, we have succeeded in overcoming the various impediments, so that we can now readily obtain values for the physical quantities that enter into consideration in our experiments.

There is a serious trouble connected with the study of the discharge in rarefied gases, for, after a very short time, the tubes completely and permanently change, so as no longer to present the splendid stratifications witnessed on a first trial. We believe these changes occur much more rapidly with the battery in consequence of the greater amount of current, than with the induction coil; but the fact appears to have been well known to Dr. Geissler, of Bonn, who, on the occasion of a visit to our laboratory, brought with him some tubes through which no current had previously passed (virgin tubes, as he called them), which presented most beautiful phenomena lost for ever after too brief a period.

Tube 123 (cyanogen), for example, when first connected with the battery, presented strata which completely filled the tube without leaving a dark space near the negative, some threading themselves on it, as shown on the left of Fig. 1; but after a few seconds the strata widened out as on the right hand figure, then other changes occurred, and the first phases have never been reproduced.

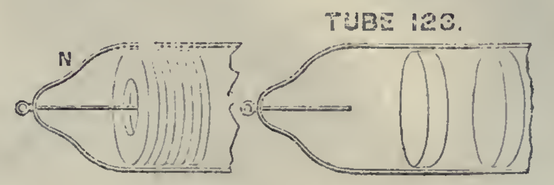

FIG. 1.

Another case is presented by the nitrogen tube Fig. 2, the right-hand figure showing the first phase, and the left-hand figure a second phase, which in its turn has for ever disappeared, and has been replaced by the ordinary disk-form of strata.

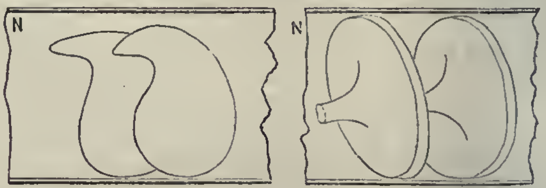

FIG. 2.

After spending much time in experiments with tubes prepared for us by Dr. Geissler, Messrs. Alvergniat Frères, of Paris, and Mr. Hicks, of Hatton Garden, with the vexation of finding that we could not often enough repeat our experiments, we ultimately came to the conclusion to have others made, but not exhausted, and to perform ourselves the charging and exhaustion. The tubes we usually employ have a glass stop-cock fitted to them at each end; they are 32 inches long, and from 1·75 to 2 inches in diameter; the terminals are of aluminium, and about 29 inches apart, one being a ring, the other a wire bent at a right angle, so as to point in the direction of the axis of the tube (see No. 144, Fig. 3), for we have found that the phenomena vary according as the ring or wire is made positive.

FIG. 3.

These we exhaust and fill with any gas we may wish to experiment with, and gradually exhaust again, noting the phenomena presented at different pressures, with different potentials, and with different amounts of current. We re-fill and exhaust the tube again and again, and mostly obtain, under the same conditions, as nearly as possible the same phenomena, of which we are careful to make sketches and, if possible, to obtain photographic records.

In some cases we make use of tubes provided with a calibrated chamber between two stop-cocks, as *a—b*, No. 145, Fig. 4, the chamber in this particular case having $\frac{1}{2200}$th of the capacity of the tube, this tube has also an absorption chamber communicating through a cock and intended to contain spongy palladium. After a tube has been exhausted so as to produce a particular phase, and in the course of the experiment the exhaustion has been carried beyond that degree which permits of the reproduction of that phase, one or more charges of gas may be successively admitted into the tube by filling the calibrated chamber with gas at any particular pressure, and then opening the stop-cock communicating with the tube; the lost phase is thus reproduced.

The apparatus which we have found it advantageous to adopt for the exhaustion of our tubes is shown in Fig. 5; it comprises three means of exhaustion which are successively employed as the vacuum becomes more perfect. The first is an Alvergniat high-pressure water *trompe* in connection with the high-pressure water-main of the

[1] See *Phil. Trans.*, vol. clxix., pp. 55-121.

[2] Mr. Gassiott made several batteries of different kinds in the course of his experiments; on the occasion of a visit to his laboratory, January 26, 1875, the current of his Leclanché battery was measured by us with a voltameter. The current of 1000 new cells was found to be 0·07464 W; that of the whole 3000 cells, 1000 of which had been a long time in use, 0·04718 W. Taking the Leclanché as 1·48 volt the internal resistance of the new battery must have been 19·83 ohms per cell; that of the whole 3000, 31·87 ohms per cell. The striking distance of the whole 3000 between a conical point and a disk 0·125 inch diameter was only 0·125 inch; whence the inference is that the insulation was, at that time, imperfect.

West Middlesex Water Company, the head of water being 106 feet; it produces a vacuum to within half-an-inch (0·47 in. = 12 millims.) of the height of the barometer. The pipe leading to it is so marked in the drawing; it is attached, through a cock, to a four-way-junction-piece F, provided with three more cocks, communicating:—one to one end of the tube T, one to the last drying bottle of the gas generator G G′, and one to a mercurial gauge. The

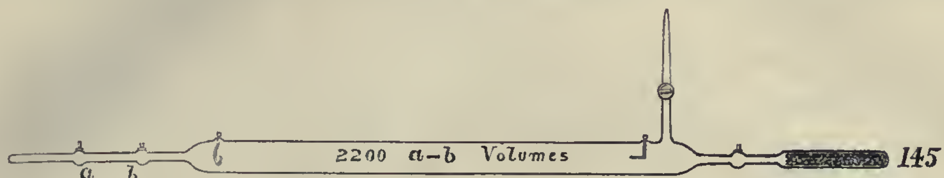

FIG. 4.

other end of the vacuum tube T communicates by means of a Y-piece to both, an Alvergniat mercurial pump, on the right of the figure, and a Sprengel pump, on the left. After the *trompe* has done its work, the Alvergniat is used for rapid exhaustion, and then shut off by means of the glass cock C, leaving the exhaustion to be completed by the Sprengel; we have thus obtained, by the *pumps alone*, in tubes 32 inches long and 2 inches in diameter, vacua of only 0·002 millimetre pressure, equal to 2·6 millionths of an atmosphere—a vacuum so perfect that the current of 8040 cells would not pass. The apparatus is in connection with a McLeod gauge, by means of which pressures to 0·00005 mm. can be determined. Besides this gauge, the Sprengel and Alvergniat pumps have their own gauges, which read to a millimetre. M is a rotating mirror consisting of a four-sided prism mounted on a horizontal axis and provided with a multiplying wheel; on each face of the prism is fastened a piece of looking-glass. The reflection of the tube in the mirror enables one to examine

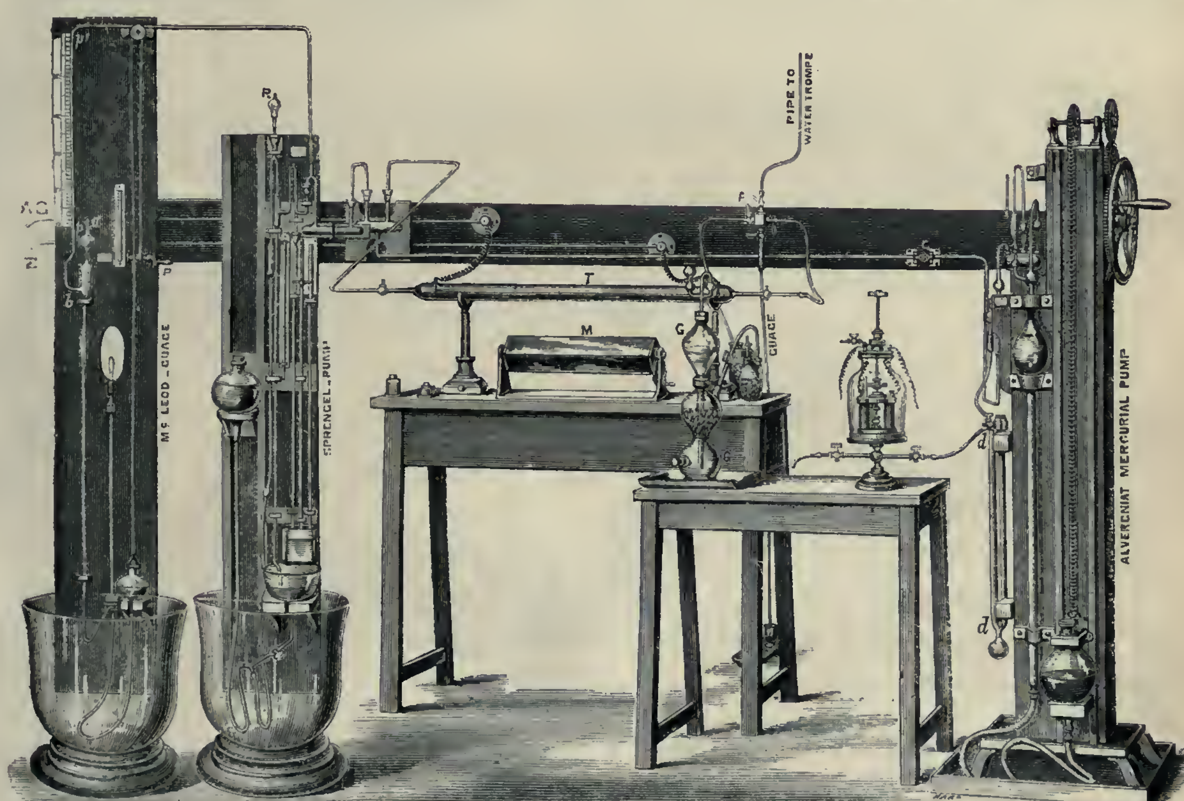

FIG. 5.

whether an apparently nebulous discharge is simply nebulous or consists really of strata, also whether and in what direction there is a flow of strata which may appear quite steady to the eye. The observations are facilitated by covering the tube with a half cylinder of cardboard having a slit in the direction of its axis about $\frac{1}{10}$ inch wide. R is a radiometer attached to the Sprengel; *d*, *d*, a drying tube containing sticks of potash used when gas is introduced from a reservoir through the Alvergniat.

The resistance of vacuum tubes does not depend solely or mainly on the distance between the terminal, but it does greatly on their diameter.

In order to test how much of this depends on the length of any constriction, we had made two tubes, 154 and 155, Fig. 6, of nearly the same length (16 inches), and internal diameter $\frac{15}{16}$ths of an inch, the residual gas in each case being carbonic acid, CO_2. From results obtained with these tubes where the constricture varied in length in the ratio of 125 to 1, it became evident that the main effect is due to the simple constricture of the tube.

The diagram Fig. 7, shows the arrangement by which,

in our early experiments, we measured the resistance of a tube. The tell-tale tube[1] had to be substituted for the galvanometer in the ordinary Wheatstone bridge, as the difference of potential between C and D fluctuated greatly

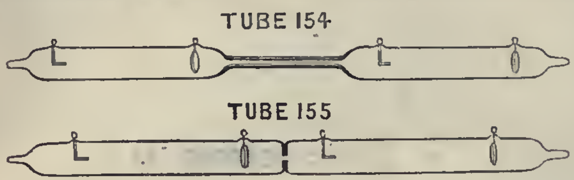

Fig. 6.

in the course of the experiment, causing violent swings of the needle.

A Z is the battery, the A terminal of which is connected at A′, in the bridge arrangement, with two equal fluid resistance tubes, FR and FR′, of 420,000 ohms, placed in vessels containing ice, to keep them at a constant temperature; an adjustable coil resistance is inserted between B and D; the tube T T′, to be tested, is placed between D

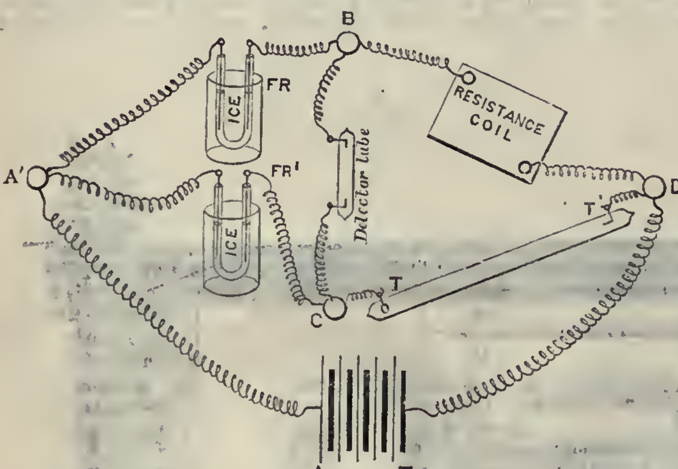

Fig. 7.

and C, the Z terminal of the battery being connected to D. When the resistance is greater or less than that of the tube to be tested there is an illumination in the detector tube between B and C; but when a current passes in T T′, balanced by a proper adjustment of the coil resistance, then the glow in the detector ceases. It was ultimately found that the detector tube might be suppressed because, as soon as the resistance in B D is a little in excess of that of the tube, the latter gives evidence by its illumination of the current passing. After the current in a tube has commenced it is generally found that it will continue to glow, even when some of the balancing resistance, B D, is plugged out in the coil box, showing that when once started the *working* resistance becomes less. If, on the other hand, the current has been stopped entirely, it requires generally a greater balancing resistance in the coil box between B D to start it again than it did in the first instance. After standing for a short or long time it regains its normal condition, but the interval required may amount to several days. The following numbers were obtained:—

Tube	Started with ohms.	Ran up to ohms.	Nature of the Gas.
1	200,000	250,000	
2	350,000	500,000	
6	270,000	500,000	N
42	15,000	70,000	N
81	150,000	infinity.	CO_2
95	700,000	1,000,000	SiF_6

Subsequently we found it to be more convenient not to make special determinations of the resistances of the tubes beforehand in the way just described, but to obtain them by reproducing the deflection of a galvanometer by substituting wire resistances for the tube, or by measurements taken with an electrometer in the manner to be described, while observing the phenomena of stratification.

From measurements thus made with a tube having several rings about 1 inch apart (No. 25, like in Fig. 9), or a Spottiswoode tube with a shifting terminal (No. 147, Fig. 8), we found that the resistance of a vacuum tube, unlike that of a wire, does not increase in the ratio of the distance between the terminals for the same gas at the same pressure.

In making these experiments it was noticed that the resistance for equal distances appeared to be greater in proximity with the negative pole than in other parts of the tube, and fresh experiments were in consequence undertaken to ascertain the potential at the several rings by means of a delicate Thomson-Becker quadrant electrometer furnished with an induction plate, I, Fig. 9, which may be adjusted to any required distance from the quadrant beneath it.[1] The tubes employed among others were No. 25, described above, and two other longer tubes, namely, No. 149 (CO_2) with 12 rings 2 inches apart, and No. 150 (CO_2) with 17 rings also 2 inches distant. The current was led through a metallic resistance to the first ring, the last ring and the other pole of the battery being to earth. It was found that the greatest difference of potential occurs between the last ring and the last but one on the negative side, the next greatest difference being between the last and the last but one on the positive side, but the difference in the former case is far greater than in the latter; in some cases there is little or no difference

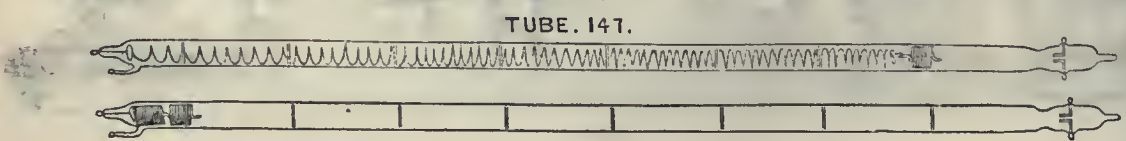

Fig. 8.

in the last but one and the last but two on the negative side; in these cases the last but one on the negative side was dark, while all the others had a luminosity about them. The difference of potential between the rest of the rings is sensibly uniform.

The following observations, made December 21, 1877, with tube 150, may be taken as an illustration of the method of measurement adopted. Batteries 6 and 7 (2,400 rod cells) were employed, and adjustable resistances were inserted in circuit for the double purpose of affording the means of readily varying the strength of current without interruption, and of enabling a measurement of that current to be made with the electrometer. The connections are shown in the diagram, Fig. 9.

[1] A tube selected for the readiness with which it permits the passage of a current of 440 cells.

[1] It has since been found more advantageous to separate the induction apparatus from the electrometer. Each pair of quadrants is charged with opposite electricities by means of two separate batteries of twenty chloride of silver cells, the opposite poles being to earth; and the induced plate of the induction apparatus communicates with the needle.

NEGATIVE POSITIVE

D.J. Pound Sculpt.

FAC-SIMILE OF PHOTOGRAPHIC

The circuit was first broken by removing the earth wire from ring 17, and the plug T, in connection with the induction plate I, being touched at any point between K′ and ring 1 gave the reading for "Full Potential, open circuit;" next, the earth wire was replaced at ring 17, and the value for "Full Potential, closed circuit," was obtained by causing T to touch at K′. As these batteries had but small internal resistance, the difference between these two readings was scarcely perceptible. By touching T at rings 1, 2, &c., in succession, their potentials were observed. The current was then reversed and similar observations were made. Next, for the purpose of

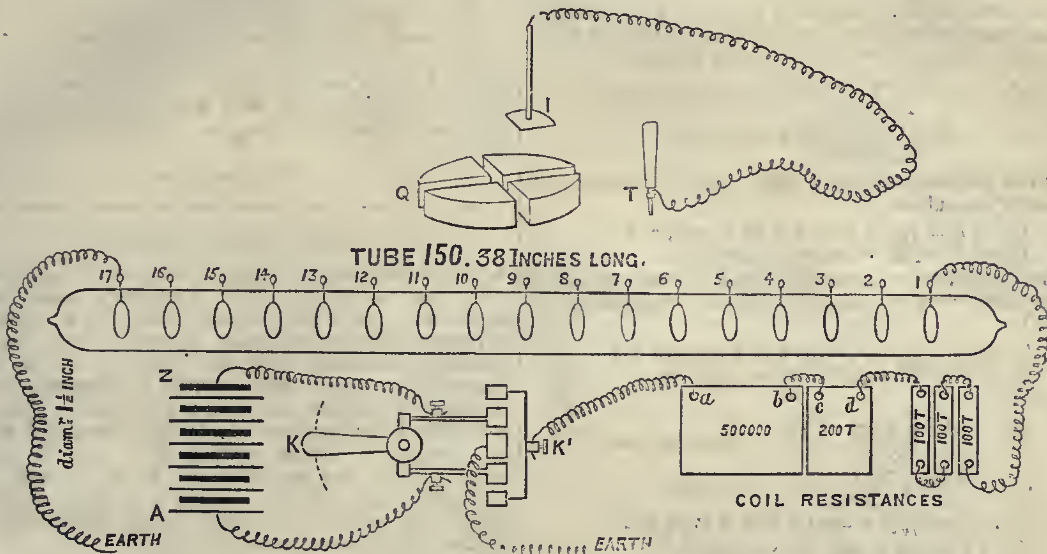

FIG. 9.

making a better examination of the tube in detail, the induction plate I was lowered to that distance which gave as large a deflection for the difference of potential between the two ends of the tube as was convenient. After the potentials of the several rings had been measured in succession with both currents, the induction plate was restored to its original position, and one or two of the first observations were repeated for confirmation. The current was then varied by altering the resistance in circuit,[1] and fresh measurements made in the same order. Thus the following values were obtained:—

I. CIRCUIT:—2,400 rod-cells, 1 megohm resistance, Tube 150: Induction plate at 2 inches distance from the quadrant

	Current +	Differences.	Current −	Differences.
Zero	6 right = 0		6 right = 0	
Full potential (open circuit) ...	154 left = 160	 1	200 ,, = 194	 2

,, (closed ,,)	193 ,, = 188	191 ,, = 186	
Potential after 800,000 ohms	166 ,, = 161	167 ,, = 162	... ... 25·5
,, at ring 1	138 ,, = 133	136 ,, = 131	 132
,, ,, 17	5 ,, = 0	5 ,, = 0	

[1] This method of varying the current is arranged to save time. The circuit must not be interrupted in the course of a set of observations.

III. The induction plate was lowered from 2 inches to $1\frac{1}{2}$ inch. Current $-$. (The current $+$ was not observed for want of time.)

Ring	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17
Readings	276	217	200	187	174	159	144	130	116	104	90	76	62	48	35	22	0
Differences	59	17	13	13	15	15	14	14	12	14	14	14	14	13	13	22	

The observation III. illustrates that which has already been said concerning the fall of potential within the tube.

In case I. we have for the currents in webers—

$$C+=\frac{\frac{47}{160}\times 2400\times 1\cdot 03}{1,000,000}=0\cdot 0007261, \text{ and}$$

$$C-=\frac{\frac{65}{194}\times 2400\times 1\cdot 03}{1,000,000}=0\cdot 0008281,$$

and for the difference of potential in volts (V) between the two ends of the tube—

$$(C+)\,V=\tfrac{112}{160}\times 2400\times 1\cdot 03=1730, \text{ and}$$
$$(C-)\,V=\tfrac{127}{194}\times 2400\times 1\cdot 03=1618.$$

These differences of potential would be reproduced if for the tube were substituted metallic resistances in ohms (R)—

$$(C+)\,R=\tfrac{112}{47}\times 1,000,000=2,383,000, \text{ and}$$
$$(C-)\,R=\tfrac{127}{65}\times 1,000,000=1,954,000.$$

In case II.—

$$C+=\frac{\frac{19\cdot 5}{164}\times 2400\times 1\cdot 03}{800,000}=0\cdot 0003674, \text{ and}$$

$$C-=\frac{\frac{25\cdot 5}{188}\times 2400\times 1\cdot 03}{800,000}=0\cdot 0004190.$$

$$(C+)\,V=\tfrac{116\cdot 5}{164}\times 2400\times 1\cdot 03=1756, \text{ and}$$
$$(C-)\,V=\tfrac{132}{188}\times 2400\times 1\cdot 03=1736.$$
$$(C+)\,R=\tfrac{116\cdot 5}{19\cdot 5}\times 800,000=4,780,000, \text{ and}$$
$$(C-)\,R=\tfrac{132}{25\cdot 5}\times 800,000=4,142,000.$$

Selecting the observations with the current positive in each case and placing these in juxtaposition thus—

	C		V		R
Case I.	0·0007261	...	1730	...	2,383,000
,, II.	0·0003674	...	1756	...	4,780,000

we see that when C is varied in the ratio of 2 : 1, V remains sensibly constant, R varying as 1 : 2; that is to say, though the current is halved, the difference of potential between the ends of the tube remains constant —a condition which could only be brought about when metallic resistance is substituted for the tube, by doubling this resistance.

This points to the important conclusion that *other things being kept constant* and the current alone varied, we should find the value of V *strictly* constant for all values of C; but it may readily be imagined that in experiments with "vacuum tubes" it is not easy to ensure perfect constancy of the accompanying circumstances.

To test this conclusion we extended the range of our observations by varying the value of C as much as from 1 to 135.

In the paper are given the original measurements themselves, not the mean results, in order that the discrepancies in the readings obtained for V when C was kept as constant as our powers of control permitted, might be compared with the variations, such as they are, in the values of V when the circuit was purposely varied so as to produce currents of different strengths. Our observations show clearly that discharge through rarefied gases cannot be at all analogous to conduction through metals; for a wire having a given difference of potential between its ends can permit one—and only one—current to pass; whereas, from the measurements obtained it became evident that with a given difference of potential between the terminals of a given vacuum tube, currents of strengths varying from 1 to 135 can flow. We are therefore led to the conclusion that the discharge in a vacuum tube does not differ essentially from that in air and other gases at ordinary atmospheric pressures—that it is, in fact, a disruptive discharge.

By fixing small rings of tinfoil to the glass near the places where the metal terminals are fused into the tube and connecting these rings to earth, we were able to cut off the leakage over the surface (which, in spite of precautions, is considerable), and prevent it from interfering with our measurements of the potential of the gas *inside* the tube.

(*To be continued.*)

NORTHERN BORNEO

SOME time ago (NATURE, vol. xviii. p. 454) we were able to give a few particulars respecting the acquisition, by a British association, of a considerable portion of Northern Borneo, a region which has never yet been thoroughly explored. Under the title of "North Borneo," the promoters of this association have just printed for private circulation a 4to volume, containing a sketch of the territory of Sabah, lately ceded to them, and a report on various portions of the same by a Ceylon planter, which are accompanied by an analysis of soils and three appendices. The volume also contains two maps of Borneo, but the details given therein about the northern part are necessarily meagre.

The territory of Sabah comprises an area of some 18,000 square miles, possessing the great advantage of a coast-line of 500 miles from the Kimanis River on the north-west coast, to the Sibuco River on the east side of the island; it has the finest and almost only good harbours in Borneo, viz., Gaya Bay, Ambong, and Ousukan Bay on the west, and Sandakan Harbour on the east coast, the first and last named of which will, no doubt, become of great importance, especially if it be true that there is coal close at hand. The whole of Sabah is traversed by a mountain range of 5,000 to 8,000 feet in height, which culminates in the Kini Balu mountain, 13,700 feet high. To the east of this is the supposed position of the Kini Balu Lake, which no European has yet visited. On the shores of the lake, according to native reports, there are many villages of Ida'an, who cultivate cotton, tobacco, &c., and are said to be peaceful and industrious. There are numerous rivers on the north-west coast, but owing to the proximity of the high mountain ranges they are said to be only navigable by light craft; on the east coast, however, there are several splendid rivers, the Paitan, Sibuco, and Kinabatangan, the latter of which is believed to be navigable by large steamers for several hundred miles. As far as has been at present ascertained, the spurs and slopes of the Kini Balu range seem well fitted for the cultivation of coffee, tea, and cinchona, and the level country on the banks of Kinabatangan for sugar, indigo, tapioca, tobacco, cocoa, cotton, and rice. The Sabah territory is believed to be but sparsely peopled, the total population being estimated at 150,000 to 200,000; the interior is inhabited by descendants of the aborigines, called variously Muruts, Dusuns, or Ida'an, and corresponding in their external appearance in many respects to the Dyaks of Sarawak and the southern parts of the island, though they are of a lighter hue. The climate of the region is believed to be very favourable; in the plains and low-lying lands near the sea and rivers an invigorating breeze is generally felt during the day, the thermometer seldom ranging beyond 86°, while the nights are cool, with a temperature sometimes below 70°. No data are yet available in regard to the rainfall, but it is believed to be very similar to that of Ceylon. The soil is rich and fertile, and in many locali-

ties of superior quality. The chief vegetable productions indigenous to the soil and growing wild in the forests are india-rubber and gutta-percha, baroos camphor and gum damar, and many valuable kinds of hard-wood timber. Rice, millet, tapioca, Indian corn, sugar-cane, tobacco, cotton, pepper, and many kinds of tropical vegetables are cultivated by the natives. The sago palm is found in abundance, cassia lignea is met with in some localities, and cocoa-nuts, the areca palm, mangoes, limes, oranges, bananas, and pine-apples are plentiful. Under the head of animal productions the report mentions edible birds'-nests, beeswax, hides and horns of cattle and deer, mother-o'-pearl shell, seed pearls, bêche de mer or trepang, and tortoise-shell; elephants exist in the Kinabatangan province in large numbers; rhinoceros, numerous deer of large and small breeds, and wild pigs are met with in many parts, but beasts of prey of the feline species appear only to be represented by a small cheetah in the interior. Minerals will, doubtless, be found in abundance in Northern Borneo. Gold occurs in several localities. Borneo diamonds are famous for their purity and water, and it is believed that they exist in Sabah as well as in Dutch territory. Tin, antimony, coal, quicksilver, iron, copper, petroleum, and other valuable minerals and metals, there is reason to believe, will be found in the territory of the association, but there has not yet been time for even a partial exploration of it from a geological and mineralogical point of view. The labour question may cause some little trouble. The population near the coast consists of Malays, Lianuns, Bajous, Sulus, and others of a mixed breed who are lazy, indolent, and averse to manual labour of any kind. The aborigines in the interior, Dusuns and Ida'an, are peaceful and docile, and accustomed to a certain kind of labour. But the company will not have to rely upon either for the development of their territory, for, as the report puts it, "the enormous amount of labour waiting for employment in the Chinese Empire, not more than three or four days' distance by steam from North Borneo, is at the disposal of intending planters and others . . . on reasonable terms."

VULCANOLOGY IN ITALY IN 1878[1]

A FEW years ago Cav. Michele Rossi, brother and collaborateur of the well-known author of "Roma Sotterranea," determined to try the experiment of collecting together from all parts of Italy facts connected with Vulcanology, and publishing an account of them in the form of a monthly fasciculus. He hoped by this means to found a new school for the study of endogenous meteorology, to be affiliated with the study of meteorology proper. The experiment has succeeded admirably, and we have before us a volume of 140 pages, recording all the phenomena of internal telluric dynamics which have been observed in Italy and Sicily during the past year. The vulcanology of Sicily, notably of Etna and the eastern sea-board, is also recorded in the Acts of the Accademia Gioenia of Catania. In no other part of Europe, except Iceland, would it be possible to have a journal solely devoted to the volcanic phenomena of one country. The kingdom of Italy contains within it the two most famous volcanoes in the world; it contains solfataras, soffioni, and maccalube; it is subject to earthquakes, sometimes of great severity, and spread over large areas; the district between Naples and Cape Misenum embraces almost every phase of volcanic phenomenon, excepting only the geysirs, and the Stufe di Nerone belong to this class of effects. Hence, obviously, there is no country of equal accessibility in the world which is so well adapted for the study of vulcanology.

The *Bullettino* opens with a tribute to the memory of Padre Angelo Secchi, which is followed by a proposition to erect a monument to his honour. We were glad, a few weeks ago, to notice that a well-executed bust of the great Roman astronomer had already been placed among those of the many celebrities which adorn the Pincian Hill. The new monument will probably take the form of a *monumento meteorologico*, to be erected in Rome.

A list of twenty-six Italian observatories in which seismic observations are recorded is given in the *Bulletino*, with the names of the observers, who are in direct communication with Prof. de Rossi. Among the minor notices we find mention of the proposed railway to the observatory of Vesuvius; of various new seismological observatories, including that of the Solfatara at Puzzuoli; and of the earthquake which was simultaneously felt at Fiumalbo, Florence, and Rocca di Papa. Bibliographical notices and correspondence find a place at the conclusion of the fasciculus. In the next number we find letters on the application of the microphone to seismological studies, from Prof. Michele Rossi and Count Giovanni Mocenigo, and later in the volume a very interesting article by the former details his experiments on the subject. The Umbrian earthquake of September, 1878, receives full description at the hands of Prof. Arpago Ricci; Silvestri gives an account of the mud eruption which broke out on the sides of Etna near Paternò in December; and Palmieri continues his "Cronaca Vesuviana" to the end of September, 1878. An exact account of the time of occurrence of earthquake phenomena in any part of Italy is entered in a tabular form, and it is surprising to notice that not a day passes in Italy without some indication of endogenous dynamic action. This also proves to us the sensibility of the instruments. The date is given, then the hour, the place, and the nature of the observation, thus:—

"13.—0.08 a. Messina, forte.—Reggio di Calabria, due scosse.—Palmi, scosse.—Capo Spartivento, molto forte.—Tropea, leggera ondul.

1.15 a. Corleone, leggera E—O, rombo.
5.50 a. Tolmezzo, debole; altra poco dopo.
7.15 a. Narni, sensibile N O—S E.
Mattina Rocca di Papa, leggerissima.
11.15 a. Bologna, leggerissima."

At the conclusion of the volume there is a large table showing at a glance the daily distribution of earthquakes throughout Italy. Twelve vertical divisions correspond to the twelve months of the year, and these are further divided by small lines into days. The horizontal lines serve to indicate:—

1. In the uppermost portion of the diagram the height of the barometer in millimetres. Thus we have the barometric curve for each month.
2. Here also is shown the variations during each month of the level of the water in the wells of Leghorn and Porretta.
3. Earthquakes according to the latitude.
4. Earthquakes according to the longitude, east and west of the meridian of Rome.
5. Daily maxima of the force of the shocks.
6. Phases of the moon.
7. Daily maxima of the number of the shocks.

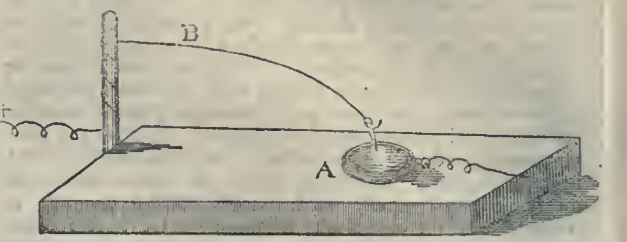
In Prof. Michele Rossi's seismological observatory in Rome we saw at work a set of instruments devised by himself for registering both vertical and horizontal shocks. These are not the same as Palmieri's instruments, and are said to be more sensitive. In both sets of instruments the general principle is the same. The shock, by its movement, communicates motion to some appliance, such as a pendulum, or a column of mercury in a bent tube, which establishes electrical communication with a recording instrument. In the latter a ribbon of paper is drawn at a definite rate over a drum, and whenever electrical contact is established a small electro-magnet becomes active and draws down an armature to which a pen is attached, and for every contact a mark is made upon the

[1] Bulletino del Vulcanismo Italiano. Periodico geologico ed archeologico per l'osservazione e la storia dei fenomeni endogeni nel suolo d'Italia. Redatto dal Cav. Prof. Michele Stefano de Rossi. Roma, 1878.

paper ribbon. The length of paper corresponding to an hour of time being known, it is easy to determine the instant at which the mark has been made, viz., the instant at which the shock has occurred.

Without any doubt the most interesting article in last year's *Bulletino* is that on the application of the microphone to the study of subterraneous meteorology, by Prof. Michele de Rossi. In 1875 Count C. Mocenigo, of Vicenza, made an observation which was nothing less than the fundamental fact of the microphone, at a time when neither microphone, phonograph, nor micro-tasimeter had been invented. He observed that electric currents indicate perturbations and interruptions in a galvanometer by means of frictions and shocks produced artificially between conductors not in perfect contact ("per effetto soltanto di attriti e di scosse communicate artificialmente ai conduttori posti fra loro in semplice contatto instabile"). He also observed that the same phenomena were produced by natural and unknown causes, when the apparatus had not received any artificial shock.[1] The account which he gave of his observations led Prof. de Rossi to conclude that these unknown perturbations arose from microseismic oscillations of the soil. He communicated his views to Count Mocenigo, who at once commenced to make experiments in the direction indicated, in the midst of which the news of the invention of the microphone in America, was received. Prof. de Rossi at once endeavoured to apply it to the detection of subterranean phenomena, and for this purpose he commenced a series of experiments in the seismic observatory which he has established at Rocca di Papa, one of the Alban Hills about seventeen miles from Rome. A special microphone consisting of a balanced pointed lever lightly touching a plate of silver, was mounted on a stone pedestal, and was placed twenty metres underground, at a distance from habitations and from roads. It was also thoroughly isolated and shut up in a box filled with wool. The instrument was watched during some of the stillest hours of the night, and the same mysterious sounds which Count Mocenigo had recognised were heard by de Rossi, which he considers were incontestably natural and intra-telluric. The sounds were carefully analysed, and were compared with artificially produced sounds. The microseismic sounds were speedily differentiated from other sounds, and their nature was completely confirmed when it was observed that they were often coincident with movements of the seismograph, and that they were of a periodic character. On one occasion, as de Rossi was listening at about half-past three o'clock in the morning the telephone connected with his subterranean microphone emitted sounds like the discharge of musketry, of such loudness that he feared they would awaken a child who slept in the same room, and he therefore disconnected the telephone. A short time afterwards, towards four o'clock, a sensible shock of earthquake occurred, for which the sounds had been the microphonic preparation.

In the beginning of last September Vesuvius showed many signs of an approaching eruption. During the night of the 22nd of that month the mountain produced thundering sounds, and at the same time loud metallic noises were heard in the microphone, more than a hundred miles distant. The microphone was soon afterwards transported to the observatory on Vesuvius, and it was then possible to trace the precise correspondence between the movements of the seismographs and the sounds of the microphone, and moreover to ascertain the seismic value (*il significato sismico*) of the different sounds of the microphone. It was also ascertained that if a watch were connected with the microphone, the noise of the tic-tac heard in the telephone became much louder just before a shock, and gradually less and less loud as the seismic agitation died away. This led Prof. de Rossi to improvise a microphone which he has found very useful for microseismic purposes.



A watch, A, is placed upon a suitable stand, and a thin copper wire, B, connected with the positive pole of a small battery is arranged, as shown in the figure, so that one end of it, furnished with a steel needle, rests lightly upon the smooth silver surface of the watch. The handle of the watch is connected by the wire with the telephone, the other binding screw of which is connected with the negative pole of the battery. Such an arrangement furnishes a very effective microphone, if the degree of contact between the needle and the surface of the watch be carefully regulated.

G. F. Rodwell

[1] "Fenomeni singolari di interferenza fra le correnti elettriche ed i promossi mecanicamente sul legno."—Bassano, 1875.

OUR ASTRONOMICAL COLUMN

The Occultation of Antares, July 28.—The only occultation of a very conspicuous star during the present year which is visible in this country and in fact the only one higher than the second magnitude up to the year 1883, is that of Antares on the evening of July 28. It will take place at a low altitude here. As is well known Antares is a double star, and the effect of the duplicity was shown by observation of the occultation of the star by the moon, before the companion was detected by Mitchel at Cincinnati in July, 1845. The appearance of a comparatively faint star at emersion, suddenly brightening up to the full brilliancy of Antares, had been recorded, and a suspicion of duplicity entertained at least in one instance, some twenty years previous. Interest therefore attaches to the occultation of July 28, and with the view to facilitate the determination of the times of immersion or emersion at any place in this country, we will apply the Littrōw-Woolhouse method of distributing the prediction of the phenomenon. Direct calculations give the following results for Greenwich, Edinburgh, and Dublin; the moon's place is corrected nearly to agree with Newcomb's theory:—

	Greenwich M.T. of Immersion. h. m.	Angle from N. Point. °	Greenwich M.T. of Emersion. h. m.	Angle from N. Point. °
Greenwich.	9 38·11	153·3	10 7·03	200·2
Edinburgh.	9 38·53	166·5	9 49·93	184·9
Dublin ...	9 33·05	161·4	9 50·53	189·0

From which, putting the latitude of the place $= 50° + L$ (L in degrees), and the longitude in minutes of time $= M$ (+ if east, − if west of Greenwich), we find—

$$\text{G.M.T. of Immersion} = \overset{\text{h. m.}}{9\ 36{\cdot}86} + 0{\cdot}841\,L + 0{\cdot}263\,M$$
$$\text{,, Emersion} = 10\ 10{\cdot}74 - 2{\cdot}507\,L + 0{\cdot}462\,M$$

$$\text{Angle from N. Point at Immersion} = 149{\cdot}4° + 2{\cdot}6\,L - 0{\cdot}1\,M$$
$$\text{,, ,, Emersion} = 204{\cdot}2 - 2{\cdot}7\,L + 0{\cdot}2\,M$$

These formulæ give for—

	Immersion. h. m.	Angle. °	*Emersion.* h. m.	Angle. °
Cambridge ...	9 38·7	155	10 5·2	198
Oxford	9 37·0	155	10 4·0	198
Liverpool ...	9 36·5	160	9 56·5	192

Which are Greenwich mean times: the angles are reckoned as is usual in the occultation-predictions of the *Nautical Almanac*, for the inverted image. At Greenwich

the altitude of the star at emersion will be $7\frac{1}{2}°$, and at Edinburgh $5\frac{1}{2}°$.

Suppose, for the sake of an example of the application of the above formulæ, it is desired to know the Greenwich mean times of immersion and emersion of Antares as viewed from Brighton, which place we will assume to be in latitude 50° 50′ and longitude 0m. 32s. west of Greenwich. We have then $L = +0°.83$, and $M = -0.53$m; it will be sufficient to include the second decimal only in the factors for L and M in the formulæ:—

For the *immersion*—

$(+0.83) \times (+0.84) = +0.70$
$(-0.53) \times (+0.26) = -0.14$

The sum $+0.56$m., added to 9h. 36·86m., gives 9h. 37·4m. for G.M.T.

For the *emersion*—

$(+0.83) \times (-2.51) = -2.08$
$(-0.53) \times (+0.46) = -0.24$

The sum -2.32m., added to 10h. 10·74m., gives 10h. 8·4m. for G.M.T.

Similarly the angles will be found to be 152° at immersion and 202° at emersion.

The companion of Antares preceding the principal star nearly on the parallel will emerge several seconds earlier.

The Great Comet of 1874.—Just five years since, as we write, the comet discovered by M. Coggia at the Observatory of Marseilles on April 17, 1874, was beginning to attract general attention as a naked-eye object in the evening sky. The orbit, the determination of which presented some difficulty at first, from the slow motion of the comet, had been ascertained with sufficient precision to enable astronomers to predict its conspicuous appearance in the first half of July, and the track it would follow when, descending below the horizon in Europe, it became a favourably-situated object for the observatories of the other hemisphere. It was observed in Europe until July 16, and about a week later was seen in Australia; observations were continued till October, the last being made at the Argentine Observatory, Cordoba, on the 18th of that month, when it had receded to a distance of 1·94 from the sun and 1·79 from the earth, and was situate about 12° from the south pole of the heavens.

The European observations during three months were found to indicate a sensible, though not very material deviation of the orbit from a parabola, and ellipses were calculated at the time by Tietjen, Schulhof, and Geelmuyden. In a late number of the *Astronomische Nachrichten* are elliptical elements founded by M. Seyboth, of Riga, upon the meridian observations made at Moscow, which appear to possess a very high degree of precision, though they extend over an interval of twenty-six days only. The periods of revolution assigned by these computers are:—

Tietjen	8,965 years.
Schulhof	12,184 ,,
Geelmuyden	10,445 ,,
Seyboth	5,711 ,,

The differences between these periods show that beyond establishing the fact that the comet was moving in an orbit with a period of revolution extending to several thousand years, no reliable approximation to its true length has yet been obtained, but the additional three months' observations in the southern hemisphere have not hitherto been brought to bear upon the determination of the elements. The last Cordoba observations give the following final position:—

1874, October 18, at 14h. 46m. 58s. G.M.T.

	° ′ ″
Apparent Right Ascension	99 46 27·0
,, Declination	−77 42 36·6

If we compare the elements of Geelmuyden and Seyboth with this observation, taking aberration into account, we find the following differences:—

	Error in R.A. ″	Error in Decl. ″
Geelmuyden	+ 31	+ 65
Seyboth	+ 59	+ 99

so that while, as tested by this single observation, the longer period of revolution appears to have the advantage, it is sufficiently evident that ellipses with divergent periods may eventually be found to represent the observations with almost equal precision, or in other words the length of the revolution will remain open to considerable uncertainty. If the deviation of the form of the orbit from the parabola, which satisfies the motions of the majority of comets be due to planetary attraction, we might look to Venus as the agent, since at the descending node the comet in 1874 approached the orbit of that planet within 300,000 miles (0·00325 of the earth's mean distance); the opposite node falls at a radius-vector of 11·65. The aphelion distance, according to Geelmuyden's calculation would be 955·0, or the comet would have travelled to these parts of space from a distance exceeding by more than thirty times the mean distance of Neptune.

GEOGRAPHICAL NOTES

The Abbé Debaize, who by previous accounts was at Igonda on March 20, seven days' journey from Ujiji, has written under date of April 2 from the latter place to the director of the Paris Observatory and others, giving a brief sketch of his immediate plans. He proposes to take all his porters and merchandise by water to the Uzighé country at the north end of Lake Tanganyika, and to form a depôt there, which he will leave in charge of some of his best men; he will then establish a second depôt at the mouth of the Aruwimi, the great northern tributary of the Congo. Afterwards, starting in light marching order, he hopes to be able to explore the western slopes of the Blue Mountains, the countries situated between the southern end of Albert Nyanza and Lake Tanganyika, and especially Unyambongu, Mpororo, and Ruanda. He will then return to his depôt in Uzighé, whence he will send home an account of his discoveries, as well as a statement of his future plans.

An interesting and extremely well written pamphlet has just appeared in the "Sammlung gemeinverständlicher wissenschaftlicher Vorträge," edited by Prof. Virchow and Herr von Holtzendorff. Its title is "Die Tiefsee und ihre Boden und Temperatur Verhältnisse," its author Dr. Georg von Boguslawski, the well-known editor of the *Annalen der Hydrographie* at the Imperial Admiralty of Berlin. The writer first gives a clear and concise account of all expeditions sent out by various countries for the investigation of the depths of the sea, particularly those of the *Gazelle*, the *Challenger*, and the *Tuscarora*. He then enters at greater length upon a discussion of the results obtained hitherto, treating first of the depths themselves, then of the outlines and physical condition of the sea-bottom, and finally of the distribution of temperatures and the inter-oceanic currents, with their causes and effects. Our space does not permit us to enter into details at greater length, suffice it to say that the little work is a welcome and valuable addition to scientific literature.

The Geographical Department of the Japanese Government, which is displaying considerable activity in many directions, has commenced the publication in sheets of a large plan of the city of Yedo, showing the various divisions, streets, bridges, &c., and giving the names in Japanese and Roman characters.

Under the title of "Voyage d'Exploration dans l'Intérieur des Guyanes," the *Tour du Monde* has commenced the publication of Dr. Jules Crevaux' account of his journey in 1876-7 through French Guiana and across the Tumac Humac range to the Amazons. The illustrations are very interesting and well executed, and there is also a sketch map of the region.

THE *Annalen der Hydrographie*, Heft v., contains an important article on the Movement of Water in Rivers, based on river observations at various depths of water, made at the lightship station on the Genius Bank, in the Jade, from October 17 to December 10, 1878.

M. GUSTAVE MOYNIER, as Director, and M. Ch. Faure, as Editor, announce the publication of a new geographical journal—*L'Afrique*—entirely devoted to Africa. It is proposed to embrace in it the gist of all that is important published anywhere relating to the continent with which the journal deals. It will be published monthly by M. Jules Sandoz, Geneva, the size being sixteen pages octavo.

AN *Annuaire des Sociétés de Géographie* will shortly be published in Paris.

WE learn from *Vanity Fair* that a party, of which Lady Florence Dixie was the only lady, has just returned from South America, where they "crossed many hundreds of miles of the wild and unexplored pampas of Patagonia, penetrating amidst the Cordilleras into splendid scenes hitherto unexplored and unseen by man."

THE *Bulletins* of a number of foreign societies are to hand The new number of the *Bulletin* of the Lyons Geographical Society contains, besides the annual report, the conclusion of M. Luciano Cordeiro's chapters on the first explorations of Central Africa and the Portuguese doctrine of African hydrography in the fifteenth century, and the first part of an essay on Central Asia, by Col. Debize. In this number he deals with Eastern Turkestan, illustrating his remarks with a sketch map of North-Western China and Kashgaria.—The last number of the *Bulletin* of the Société de Géographie Commerciale of Bordeaux contains a second paper on the subject of the commercial exploration of Ferlo, an almost wholly unknown region of Senegambia.—The May number of the *Bolletino* of the Italian Geographical Society contains a learned and able lecture by Prof. Marinelli, on Scientific Geography, in which he traces the progress of this department, and shows how comprehensive and important it is.—The last number of the *Bulletin* of the American Geographical Society (No. 2 of 1879) contains a paper by Major A. G. Constable on Afghanistan. Major Constable served in the English army in the former Afghan war.—The May number of the *Bulletin* of the Paris Geographical Society contains a full report of the proceedings at the recent Cook Centenary in Paris, including a descriptive catalogue, by Dr. Hamy, of the articles exhibited during the celebration, and the cartography and bibliography of Cook's voyages, by Mr. James Jackson. An accompanying map shows the routes followed by the English navigator in his various voyages.

NOTES

FOR the fine plate of tubes in this week's number, illustrating the paper by Messrs. De La Rue and Müller, as well as for the numerous woodcuts, we are indebted to the liberality of Dr. De La Rue.

IT is gratifying to find foreign governments and societies so ready to show their appreciation of our eminent scientific workers. Last week we announced the election of Prof. Huxley as a Corresponding Member of the Paris Academy of Sciences, and now we have to chronicle a double honour just received by Prof. Stokes of Cambridge: the Emperor of Germany has conferred upon him the Order "Pour le Mérite," and the Paris Academy have elected him a Corresponding Member in the section of Physics in place of the late Prof. Ångström.

DR. DONDERS has been elected in the section of Medicine and Surgery in the same Academy, to succeed the late Prof. Ehrmann.

THE candidates whose names we have already given were elected Fellows at last Thursday's meeting of the Royal Society.

PROF. SIR C. WYVILLE THOMSON was last week compelled, from sudden indisposition, to relinquish his course of lectures at the University of Edinburgh. We are glad to be able to announce that he is now completely recovered. His medical attendants, however, deem it prudent that he should abstain from lecturing again this session. His large class of between 400 and 500 students has accordingly been entrusted to Prof. Alleyne Nicholson, of St. Andrews, who will conduct it during the remainder of the session. Though dissuaded from undertaking the heavy duties of his college work, Sir Wyville, we hope, will find strength to resume his labours amid the *Challenger* materials, so that this great work, for which the world is very patiently waiting, may suffer no serious delay.

PROF. WURTZ, the eminent French chemist, has been appointed a Member of the Council of the Legion of Honour.

THE arrangements for the annual meetings of the principal foreign associations are announced. The German Anthropological Society holds its yearly meeting at Strassburg on August 11, 12, and 13, and the fifty-second meeting of the German Association of Naturalists and Physicians will be held at Baden-Baden from September 18 to 24. The French Association for the Advancement of Science will hold its eighth session at Montpellier, commencing on August 28. The president is M. Bardoux, late Minister of Public Instruction. Applications are to be addressed to 76, Rue de Rennes, Paris. The American Association meets this year at Saratoga, on August 27, the President being Mr. George F. Barker, of Philadelphia.

EARTHQUAKES would seem to be plentiful and wide-spread at present. A Reuter's telegram, of date Messina, June 17, states that continual shocks of earthquake, attributed to the volcanic action of Mount Etna, have occurred in the neighbourhood of Santa Venere and Guardia, causing serious damage and considerable loss of life. Vesuvius is stated to be showing signs of activity. A distinct shock of earthquake is reported to have been felt on Monday at Tobermory, and other places in Mull, in the Hebrides. The shock passed from north-east to south-west. On the 7th inst. an earthquake of short duration was observed at Versailles at 10·55 P.M. There was a severe shock of earthquake in Costa Rica on the night of May 29. The cathedral and many of the principal buildings of San José were shattered, and much damage was done in other parts of the republic.

DR. J. C. DRAPER is at present in this country. He has been extending his researches on oxygen in the sun (see NATURE, vol. xix. p. 352), and has read papers on the subject at the Astronomical and Physical Societies.

WE regret to announce the death of Dr. Karl Neubauer, the eminent German chemist. Dr. Neubauer died on the night of June 1-2 at Wiesbaden, where for many years he had been working in the laboratory of Dr. Fresenius. The death is also announced of Dr. Justus Ulrich, Professor of Mathematics at Göttingen University, who died on May 30.

THE Committee on Electric Lighting, recently appointed by the House of Commons, have finished hearing evidence, and issued their Report, which is in substance as follows:—"That sufficient progress has been made with electricity as a means of lighting to encourage the belief that it has an important future before it, and not only for illuminating purposes, but as a source of power which may be wisely distributed and applied to mechanical purposes. The committee are of opinion that the electric light, even in its present state of development, can be advantageously used in large areas, open or inclosed, such as large halls, squares, or railway stations; but they do not think it has been so far matured as to be able to compete with gas for

domestic purposes. They therefore do not recommend any legislation for applying the light to private purposes on the strength of its being practicable for large spaces and buildings, but they do recommend that no legislative restrictions shall be allowed to impede its further development. As to granting authority for adopting the electric light, the committee think there is already in existence sufficient power for applying it to open spaces and large centres; and, mentioning the diversity of views among the witnesses as to whether or not municipal bodies have power under existing statutes to break up streets for the purpose of laying electric light wires, they say that if such power does not exist it should be granted under proper regulations. They consider, however, that the time is not yet ripe for allowing private companies to break up streets in order to supply the electric light, but they advise that municipal authorities should receive all possible help for public lighting by electricity, and that the Legislature should be willing to give all reasonable facilities for extending the use of the electric light where proper demand for it arises. They consider further that for lighthouse purposes the electric light has established itself, but they have not been able to satisfy themselves from the evidence that electric lighting is economical as compared with gas.

THE success of the Jablochkoff lights at the Palais de l'Industrie is nightly increasing. The number of visitors exceeds 6,000 nightly, exclusive of press men, artists, and bearers of free tickets. The *salons* are rather more crowded than in daylight. No extinction at all has been noticed since the first night. The change of candles is effected by keys worked from the engine-house, and takes less than a second for each series of lamps. Several places of public entertainment in Paris are adopting the Jablochkoff light principally to avoid the heat which results from burning gas, and is so obnoxious in summer time.

As an illustration of the combination of science and commerce we may mention a new idea that has lately been carried out by a Swiss firm of chocolate-makers. We are unable to say whether the chocolate *bon-bons* have any peculiar merit in themselves, but the attraction lies in the manner of packing, the sweetmeats being put up in boxes containing two layers of small packets put up in very ornamental wrappers with coloured designs, in series representing the various branches of natural history, such as birds, butterflies, fishes, fruits, flowers, and even palæontology and geography. Each box, containing about twenty small packets of chocolate, is accompanied with a concise descriptive treatise in French written by a competent naturalist. That on birds is thus described:—"After a pleasant general introduction on the utility and charming attraction of birds, and the necessity for the protection and preservation of many, a brief sketch is given of their properties of flight, structure, organs of sense, sight, smell, and voice, respiration, nests, eggs, and incubation, moulting, geographical distribution, migration, utility to man, and general classification. Instructions are also given for preparing and mounting bird-skins, and scientific descriptions are furnished of those birds chosen for illustration either for their beauty or brilliant plumage." A similar plan to the above is adopted in other branches of natural history.

HARTLEBEN of Vienna announces the publication of an Illustrated History of Writing, a popular account of the origin of writing, of speech, and of numbers, as well as the systems of writing of all peoples. The author is Herr Karl Faulmann. The work will be illustrated with numerous coloured plates as well as woodcuts.

THE *Patriot* of Angers relates that on June 10 an immense number of butterflies were observed flying above a part of the city called Le Mail. They were travelling at a little distance from the earth, and inconveniencing persons walking in the streets. The same phenomenon was observed in Alsace, at Bisheim, on the 8th. The Bisheim butterflies were so numerous, according to the *Journal d'Alsace*, that the light of day was obscured. Their colour was red, in places tinged with grey. On the 7th the commune of Wetzikon, in the canton of Zurich, was invaded by an immense swarm of butterflies a kilometre wide, and so long that the procession took two hours to pass. They flew from two to ten metres above the ground, and went off in a north-westerly direction. Swarms of grasshoppers have recently appeared in Armenia. News from Elisahetpol states that both the banks of the River Kur were completely covered with the insects, as far as Terter on the one bank, and as far as Akstafa on the other. All vegetation is devastated.

The *North German Gazette* states that a woman in the neighbourhood of Düsseldorf, who had been bitten by a mad dog, has been cured by Dr. Offenberg, by an injection under the skin of a dose of twenty centigrammes of curare.

THE village of Mariaweiler near Düren (Rhenish Prussia) proves to be a great field of *débris* of a Roman colony. A Roman villa has just been excavated there so that most of the apartments could be measured. An inscription in one of the rooms has not yet been deciphered. The Roman coins found at the place date down to the fourth century.

FOSSIL remains of a mastodont have just been found in Vienna on the Ottakringer Strasse. Prof. von Hochstetter himself undertook the excavation of the remains. With the exception of the jaw and teeth all the bones found are much decomposed, and it will be very difficult to preserve them.

A GENEVA correspondent writes that a meteor of remarkable brightness and size was seen on June 7, about 10 P.M., in the neighbourhood of that city. It was also seen at Neuchâtel, Zug, Milan, and over its entire course its path was sinuous, presenting a strange zig-zag form. Some who saw it speak of it as having the appearance of the full moon, giving out an iridescent or greenish light. Its path was from north-east to south-west. The meteor, according to the *Times* Geneva correspondent, was seen in several other parts of the Confederation and at St. Vittore Olona, in Lombardy. Four minutes after it finally disappeared, he states, there was heard a loud report, resembling a volley of artillery. A similar report was heard in the Valaisian Alps, and almost at the same time, according to the *Gazette de Lausanne*, a shower of aërolites fell into Lake Lugano, near Melide, causing violent undulations, and nearly overturning the boats of several fishermen who were returning to port.

ON Friday last a first trial was made at Woolwich of the new 100-ton gun. The shot with which it was loaded weighed 2,010 lbs. The gun was fitted with a gas check. Its diameter was very little less than that of the bore, which has a calibre of 17¾ inches, increasing to 19¾ inches in the powder chamber. The thickness of the metal at the muzzle is about 5 inches only, but at the breech-end the chamber is surrounded with a wall of iron 2 feet 5 inch through, making the maximum diameter 6 feet 6 inches. The gun is 36 feet in length, of which the bore occupies 33 feet, and the total length of gun and carriage when run out for firing is 44 feet. The cartridge, consisting of 440 lbs. of cube powder, strongly bound in canvas and stiffened by wooden bands, was rammed home, occupying 5 feet of the bore, and then followed the projectile, the length of which was 2 feet 8 inches. The gun was fired by electricity from the instrument-room, and recoiled a considerable way up the platform, but suffered no damage either to itself or the carriage. The screens registered a velocity of 1,590 feet per second, but the projectile was found to have broken up, which may have affected the result.

THE Mayor of Liverpool has given to the Council of the Iron and Steel Institute an invitation to visit that town in September, and a deputation from the Council of the Institute waited upon

the Mayor at the Buckingham Palace Hotel on Saturday, when they discussed with him the preliminary arrangements and provisionally fixed September 24, 25, and 26 for the meeting, which will be the first held by the Institute in that town.

IN the annual report of the Deputy Master of the Mint, issued last week, we find some remarks on several points of scientific interest more or less intimately connected with the work of minting. Among these may be mentioned the adjustment of blanks by electrolytic agency, to which attention had been directed in former years. The process, originally advocated by Mr. Roberts, the chemist of the Mint, has already been employed on a large scale in the Indian Mint. The question of the change in the density of a metal by annealing is one of some importance in the operations of minting. The experiments commenced in 1877 showed that the effect of even moderate temperatures was appreciable, and the results of their continuation are given by Mr. Roberts. In connection with this subject, Mr. Fremantle remarks that it is interesting to turn to such experiments of M. Tresca on the flow of solids as have special reference to mint work, and to those which have been undertaken in the English Mint on the flow of molten metals through capillary tubes. It is hoped that the latter may ultimately throw light on the phenomenon of liquation.

THE *conversazione* of the Society of Arts will be held in the South Kensington Museum on June 25.

THE members of the International Telegraphic Conference were entertained at dinner on Tuesday night, and last night a *conversazione* was held in connection with the Conference. The labours of the Conference have been chiefly administrative and financial.

WE learn from the *Colonies and India* that rich deposits of gold have been discovered in various parts of Nova Scotia, where its existence has hitherto been hardly suspected. The most important discovery made has been near Bannockburn, in the township of Madoc, where a large nugget of gold of fine quality was recently found, and an extensive gold field is being opened out. Coal and iron are also plentiful in the province.

THE additions to the Zoological Society's Gardens during the past week include an Indian Antelope (*Antilope cervicapra*) from India, presented by the Hon. A Greville, 60th Rifles; a White-whiskered Paradoxure (*Paradoxurus leucomystax*) from the East Indies, presented by Mr. Carl Bock; two Common Paradoxures (*Paradoxurus typus*) from India, presented by Mr. G. Bradbury; a Common Magpie (*Pica caudata*), British Isles, presented by Mr. J. Loraine Baldwin, F.Z.S.; a Laughing Kingfisher (*Dacelo gigantea*) from Australia, presented by Mr. E. Hawkins; a Tuberculated Lizard (*Iguana tuberculata*) from the West Indies, presented by Dr. A. Stradling; a Caspian Ouaran (*Psammosaurus caspicus*) from Persia, presented by Commander J. Pratt, s.s. *Java*; a West African Python (*Python sebæ*) from West Africa, presented by Mr. G. H. Garrett; five Climbing Anabas (*Anabas scandens*) from India, presented by Mr. A. F. Dobson; a Tamandua Anteater (*Tamandua tetradactyla*), a Sun Bittern (*Eurypyga helias*) from South America, a Black-eared Marmoset (*Hapale penicillata*), a Brazilian Cariama (*Cariama cristata*) from South-east Brazil; a Crested Screamer (*Chauna chevaria*) from Buenos Ayres, a Daubenton's Curassow (*Crax daubentoni*) from Venezuela, a Negro Tamarin (*Midas ursulus*) from Guiana, a Spotted-billed Toucanet (*Selenidera maculirostris*), three Violet Tanagers (*Euphonia violacea*), two Saffron Finches (*Sycalis flaveola*), a Pileated Finch (*Coryphospingus pileatus*) from Brazil, a Great American Egret (*Andea egretta*), a Red and Yellow Macaw (*Ara chloroptera*) from South America, deposited; a Black Hornbill (*Buceros atratus*) from West Africa, a Green-winged Trumpeter (*Psophia viridis*) from Brazil, a Common Crowned Pigeon (*Goura coronata*) from New Guinea, two Orinoco Geese (*Chenalopex jubata*) from South America, six Melodious Finches (*Phonipara canora*) from Cuba, purchased; two Geoffroy's Doves (*Peristera geoffroii*), two Yellow-legged Herring Gulls (*Larus leucophæus*) bred in the Gardens.

THE RECENT HONORARY DEGREES AT CAMBRIDGE

IT may interest our readers to see the terms in which the Public Orator of Cambridge University spoke of the eminent men of science on whom the degree of LL.D. was conferred on June 10, as we announced last week. Mr. Sandys spoke as follows of Sir William R. Grove:—

Iuris initium a natura esse ductum auctore Tullio accepimus; iuris peritiam summam cum intima rerum naturae cognitione esse consentaneam, non modo Baconis nostri exemplo confirmatum est, sed huius quoque iudicis auctoritate defenditur. Magnum profecto rerum naturae amorem testatur oratio illa, qua tredecim abhinc annos societatis Britannicae scientiarum finibus proferendis annui praesidis munus auspicatus, in universa rerum natura ordinem quendam serie perpetua continuatum inesse docebat; testatur oratio illa altera plusquam triginta abhinc annos primum edita, qua primus indicavit lucem, calorem, vim electricam, vim magneticam, mutuam rerum quae dicitur affinitatem, ipsum denique motum, omnes alium ex alio posse generari, omnes necessitudine quadam inter se aptos et connexos esse, "ostendens" (ut Lucreti verbis utar)

> corpuscula materiai
> ex infinito summam rerum usque tenere
> undique protelo plagarum continuato.

Quod si ipse continuo tenore totam tanti ingeni vim rerum naturae cognoscendae intendisset; ille profecto qui luci electricae novum splendorem addidit, talium rerum obscuritati etiam maiorem lucem attulisset. Ceterum ille qui non modo legum scientiam sed scientiarum quoque leges optime interpretatus est, iure optimo legum doctor hodie creabitur; duplicis palmae laudem meritus, vestro omnium plausu iure excipietur Wilelmus Robertus Grove.

In introducing Dr. William Spottiswoode the Public Orator said:—

Societatis Britannicae scientiarum finibus proferendis praeses ille quem Regiae quoque Societatis praesidem hodie salutamus, fines quam amplos mathematicorum regno assignaverit, meministis omnes qui anno proximo orationem illam Dubliniensem audivistis. Imperium neque temporis neque spatii finibus terminatum illis dedit quos nonnunquam invat quasi oceani infiniti propter litora calculos numerare, nonnunquam in purum illud caelum, regionem illam inexplicabilem evolare, ubi spatium multiplex extenditur, ubi nodi tantum abest ut solvi ut ne necti quidem possint. Ipse ne Europae quidem philosophorum finibus contentus, Indorum quoque doctrinam mathematicam et antiquam linguam sacram exploravit; Asiae et Europae confinia bis lustravit, lustrata litteris mandavit. Populi in usum, ordine quam lucido lucis et coloris leges ipse illustravit; quot aliorum libros e prelo suo regio in lucem emisit, et sua et nostra cum Academia privilegiorum communium iure adhuc aliquatenus coniunctus; quanta denique liberalitate, et ministrorum suorum et populi universi liberaliter educandorum causa, pro virili parte laboravit. Ut viro integerrimo, titulis plurimis aliunde cumulato, nostri quoque tituli mantissa accedat, duco ad vos Wilelmum Spottiswoode.

Of Prof. H. J. S. Smith he said:—

Pariter iniquum esse existimavit Aristoteles ab oratore rerum omnium rationes accuratas exigere, atque mathematicum ad persuadendum apposite dicentem tolerare. Atqui ipse exemplar egregium μαθηματικοῦ πιθανολογοῦντος libenter admiratus esset, si in senatu Oxoniensium flumen orationis aureum fundentem hunc geometriae professorem audire potuisset, qui nomine duplici, et linguarum antiquarum et scientiarum mathematicarum peritia, cathedra illa dignus est quam Savilius ille, et Chrysostomi editor et interpres Euclidis, primus occupavit, occupatam annuo reditu in perpetuum ornavit. Tertii quidem ordinis linearum enumerationem Newtonus ille noster olim Latine conscripsit, hic autem, quarti ordinis lineis eadem lingua descriptis, e certamine toti Europae ab Academia Berolinensi proposito, duplicis palmæ particeps discessit. Quanta igitur spe et expectatione libros illos de recentiore quae dicitur geometria, de subtilioribus numerorum

proprietatibus, plusquam Horatianum annorum numerum huius intra scrinia clausos, iamdudum flagitamus; quos, nti par est omnibus numeris absolutos, aliquando prodituros esse speramus. Interim in negotiis Academicis singulari urbanitate diu versatus, nunc non modo collegio augurum-Britannicorum qui caeli praesagia observant praesidet, sed septemviris quoque Academiae Oxoniensi legibus conscribendis ascriptus est. Academiae illius pulcherrimae inter decora diu numeretur, diu Platonis praecepto obsecutus videat ut *οἱ ἐν τῇ καλλιπόλει* geometriam nequaquam neglegant. Duco ad vos Henricum Stephen Smith.

Of Prof. Huxley the Orator spoke thus:—

Academi inter silvas qui verum quaerunt, non modo ipsi veritatis lumine vitam hanc umbratilem illustrare conantur, sed illustrissimum quemque veritatis investigatorem aliunde delatum ea qua par est comitate excipiunt. Adest vir cui in veritate exploranda ampla sane provincia contigit, qui sive in animantium sive in arborum et herbarum genere quicquid vivit investigat, ipsum illud vivere quid sit, quali ex origine natum sit; qui exquirit quae cognationis necessitudo, inter priores illas viventium species et has quae etiam nunc supersunt, intercedat. Olim in oceano Australi, ubi rectis "oculis monstra natantia" vidit, victoriam prope primam, velut alter Perseus, a Medusa reportavit; varias deinceps animantium formas quasi ab ipsa Gorgone in saxum versas sagacitate singulari explicavit; vitae denique universae explorandae vitam suam totam dedicavit. Physicorum inter principes diu honoratus, idem (ut verbum mutuemur a Cartesio illo cuius laudes ipse in hac urbe quondam praedicavit) etiam "metaphysica" honore debito prosecutus est. Illum demum liberaliter educatum esse existimat qui cum ceteris animi et corporis dotibus instructus sit, tum praesertim quicquid turpe sit oderit, quicquid sive in arte sive in rerum natura pulchrum sit diligat; neque tamen ipse (ut ait Aristoteles) "animalium parum pulchrorum contemplationem fastidio puerili reformidat," sed in perpetua animantium serie hominis vestigia perscrutari conatus, satis ampla liberalitate in universa rerum natura "humani nihil a se alienum putat." Duco ad vos virum intrepidum, facundum, propositi tenacem, Thomam Henricum Huxley.

Finally, among the scientific men who were honoured with the degree was Mr. H. C. Sorby, of whom the Public Orator said:—

Quam magna est rerum natura, in magnis quam immensa, in minimis quam magna. Quam multa miracula, antiquis ignota, illis nuper ostendit qui minuta curiositate arcana illa quae oculorum aciem fugiunt, instrumentorum novorum auxilio perscrutantur. Hic autem ille est qui, et terrestrium et de caelo delapsorum lapidum investigandis elementis primis, primus inter Britannos talium instrumentorum usum accommodavit. Nuper societatis geologicae praeses electus, annorum triginta labores oratione cumulavit in qua vere marmoreum sibi monumentum exegit. Illud vero acutissimum quod crystallis etiam minutissimis exploratis in quibus (ut fit) pars altera est aquae plena, altera aëris quoque vacua, olim indicavit qua potissimum caloris temperie inclusa illa aqua totum illud vacuum implere, quo potissimum rerum statu saxum illud, quondam ignibus prorsus liquidum, primum durescere potuisset. Scilicet crystallum illud (ut Claudianus ait)

> non potuit toto mentiri corpore gemmam;
> sed medio mansit proditor orbe latex.
> auctus honos; liquidi crescunt miracula saxi
> et conservatae plus meruistis aquae.

Suo phaselo vectus quot maria mox lustrabit, in terra iam pridem unum saltem Argonautarum, qui terram oculis penetrabat, eatenus aemulatus, quod in intima saxorum materia perspicienda, ipse oculo potuit "quantum contendere Lynceus." Duco ad vos Henricum Clifton Sorby.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

THE Clothworkers' Company have voted 3,500*l*., over and above 10,000*l*. previously voted, to cover the complete cost of the site, building, furnishing, and fitting with all necessary appliances the textile industries and dyeing instruction departments of the Yorkshire College, Leeds, and they have further agreed to maintain the building and its operations in full effect without extraneous or adventitious aid, for a period of five years as from January 1 next, at a cost of 1,200*l*. per annum. This increased annual subvention has been necessitated by the addition of instruction in dyeing and applied chemistry connected with the finishing of textile fabrics. The new buildings will be completed about October next.

THE following awards for proficiency in Natural Science have been made at St. John's College, Cambridge:—Foundation Scholarships to W. A. Forbes, Fleming, Hart; a Proper Sizarship to Samways; Exhibitions to Lister, Samways, Stuart (already scholar), and Weldon. Forbes received also a Wright's Prize and augmentation of the year's emoluments to 100*l*. The Open Exhibition was awarded at Easter to Edmunds (University College, London), and a Second Exhibition to T. Roberts (University College, Aberystwith).

THE amended report of the Cambridge Botanic Garden Syndicate has been confirmed so far as relates to the stipend of the curator, which is fixed at 150*l*., he not to take private pupils, and to be allowed 25*l*. per annum for the rent of a house until one is provided in the garden.

PROBABLY the oldest teacher in existence is the venerable M. Chevreul. This eminent chemist, who is about ninety years of age, has been advertised as lecturer on chemistry in the Paris Museum. The first part of his lectures will be devoted to the subject of contrast of colours. M. Chevreul enjoys excellent health, and exhibits admirable bodily as well as mental activity.

THE fourth centenary of the foundation of the University of Copenhagen was celebrated in that city on the 4th inst. No less than 4,000 people took part in the celebration, including the Royal family and all the highest civic and military authorities. The festive address was delivered by the Rector Magnificus, Dr. Madvig.

SCIENTIFIC SERIALS

Bulletin de l'Académie Royale de Belgique, No. 4.—Besides communications on the blood of the lobster (Fredericq), displacement of spectral lines of stars (Spee), and perpetual motion (Plateau), we have here a paper by M. Fredericq on the theory of respiratory innervation; he is led to regard the spinal cord as containing an inspiratory centre and an expiratory centre, chloral acting to paralyse the former.—M. van der Mensbrugghe contributes a paper on new applications of the potential energy of liquid surfaces, dealing with the principal cause of loss of charge by water-jets, origin of the energy of motion acquired by waves of the sea, cause of production of bars at the mouths of certain rivers, and origin of the force of the Gulf Stream.—M. De Selys Longchamps communicates the additions to the synopsis of the Calopterygines.

Atti della R. Accademia dei Lincei, April.—We note here the following:—Influence of boric acid on acetic fermentation, by Prof. Herzen.—Distribution of subsoil water in the Agro Romano, and its influence in production of malaria, by S. Tommasi-Crudeli.—On giant-cauldrons, by S. Botti.—Geological studies on the northern Graian Alps, Italian side, by Prof. Baretti.—On the supposed identity of columbine with limonine, by SS. Paterno and Oglialoro.—On the kinzigite of Calabria, by Prof. Lovisato.—New rock-specimens from Calabria, and remarks on the serpentine formation of that region, by the same.—On the geodetic line; third general problem; analysis of spheroidal triangles, by Dr. Wurterberg.—On observations of the horizontal diameter of the sun, made at the Royal Observatory of the Campidoglio in 1878, by S. Respighi.—Catalogue of algæ gathered during the cruise of the cutter *Violante*, and especially in some small islands of the Mediterranean, by S. Piccone.—On the motion of a simple pendulum in a railway carriage, by S. di Saint-Robert.—On the difficulty of obtaining sulphuric acid perfectly free from arsenic, on the mode of obtaining it, and on some things relating to arsenic, by S. Selmi.—On the miocene strata of Siena, and considerations on the upper miocene.—On the crystalline form of anglesite of Sardinia, by S. Sella.—Obituary notice of Volpicelli, with list of published works.

Journal of the Franklin Institute, May.—Limit of efficiency in heat-engines, by Prof. Thurston.—The driving-power of leathern belts, by Mr. Cooper.—On the initial effect of the earth's rotation on the free pendulum, by Prof. Tobin.—On the measurement of tidal heights, by Mr. d'Auria.

THE *Verhandlungen des Vereins für naturwissenschaftliche Unterhaltung zu Hamburg* (vol. iii. 1876) contain, amongst other less important ones, the following papers:—On the manners and customs of the Hamrán tribe, by M. Eckardt.—On the

myths and songs from the South Pacific, by Dr. C. Crüger.—On the metamorphosis of amphibia, by Dr. J. W. Spengel.—Some diagnoses of new Heteromera, by Dr. Haag-Rutenberg.—Descriptions of some new butterflies from the Philippine Islands, by G. Semper.—On the species of the butterfly-genus *Zethera*, by the same.—On butterflies from Wladiwostock and from the Gaboon River, by Dr. C. Crüger.—On dimorphism and variations of some North American butterflies, by J. Boll.—On the metamorphosis of *Sepedon*, by G. Gercke.—On *Helix alonensis*, Fer., by H. Strebel.—Note on the geography of molluscs, by J. D. E. Schmeltz.—On the miocene formation of Reinbeck and its mollnsc fauna, by Carl Gottsche.—On the geognostical conditions of the neighbourhood of Kiel, by Dr. A. Braasch.—On petroleum springs, by S. B. Guttentag.—Ornithological notes on the fauna of the Lower Elbe, by F. Böckmann.—On the lepidoptera fauna of the same district, by L. Graeser and A. Sauber.

THE *Jahrbuch der kais. kön. geologischen Reichsanstalt zu Wien* (1879, part 1, January—March) contains the following papers:—On the metalliferous deep eruptions of Zinnwald-Altenberg (on the Saxon-Bohemian frontier), and on the tin-mining in that district, by E. Reger (with plates).—On the tertiary formation of Waldböckelheim (near Kreuznach, Rhenish Prussia) and its *polyparium* fauna, by Dr. A. von Klipstein.—On the geology of the Rhodope Mountain chain, south and south-east of Tatar Pazardžik, by Anton Pelz.—On the jurassic limestone rock *débris* in the diluvial formation of Moravia and Galicia, by Anton Rzehak.—Geological sketch of the highest part of the Sierra Nevada in Spain, by Dr. Richard von Drasche. This sketch is highly interesting and elaborate; it is accompanied by several plates and numerous illustrations.—On some limestones containing *orbitoida* and nummulites from the so-called "Goldberg" near Kirchberg, on the Wechsel Mountain (Austria), by Franz Toula.—Researches on the age of the North-Bohemian brown-coal (lignite) formation, by D. Stur.—On the productivity and the geotectonic conditions of the Caspian naphtha districts, by Hermann Abich.

THE *Moniteur Scientifique* (Paris: June, 1879), amongst numerous papers, which are noticed by us elsewhere, contains the following papers:—On the influence which a change of temperature exercises upon the deviation which inverted sugar produces upon polarised light, by Paul Casamajor.—On the acceleration in the tanning of hides by means of phosphoric acid, by E. Ador.—On "antichlore" (hyposulphite of soda), by M. G. Lunge.—On ozokerite and ceresine from Galicia, by Dr. J. Grabowsky.—Researches on the root of *Alstonia*, by O. Hesse.—On the use of anhydrous chloride of calcium as a conservative for steam-boilers, by M. Burstyn.

THE *Journal of the Russian Physico-chemical Society* (vol. xi. No. 5) contains the following papers:—On the amines containing tertiary alcoholic radicals, by M. W. Rudneff.—On tertiary isosulphocyanates, by the same.—On the polarisation of electrodes, by M. A. Sokoloff.

THE *Rivista Scientifico Industriale* (Nos. 8 and 9, 1879).—From these numbers we note the following papers:—On a direct application of the free fall of bodies, by G. Mocenigo.—On the atmospheric whirlstorm of February 24—25, by Prof. L. Respighi.—On a telephonic microphone for demonstration at schools, by Prof. G. Cantoni.—On a new method to determine the specific gravity of liquids, by Prof. M. Cagnassi.—On some new phenomena connected with the plasticity of solids, by Prof. C. Marangoni.—On some phenomena due to the viscosity of liquids, by the same.—On sand showers, by Prof. Tacchini.—On a telephotographic apparatus with a single wire, by Prof. C. Perossino.—On the magnetic properties developed in nickel and cobalt by induction compared to those of iron, by Prof. T. Martini.—On a new steelyard-densimeter, by Dr. C. Chistoni.

THE *Revue Internationale des Sciences* (May, 1879) contains the following papers:—On the glacial epoch, by Th. Kjerulf.—On the reciprocal assistance which descriptive and geographical zoology may render to each other, by M. Lataste.—On the colouring-matter of urine, by M. Masson.—On the mechanical theory of the position of leaves, by Dr. Schwendener.—The number, besides the above, contains an interesting account of the organisation of medical instruction at Lyons, as well as an excellent review by M. C. Issaurat of Dr. F. Isnard's new book entitled "Spiritualisme et Matérialisme." This serial has considerably improved since it appears only in monthly parts instead of in weekly numbers as it did up to the beginning of 1879.

Mittheilungen der naturforschenden Gesellschaft in Bern (Nos. 923-936, 1877).—From this part we note the following papers of interest:—Botanical and geological notes from a tour in the province of Reggio in Calabria, by J. Coaz.—On the most important conditions of shape in the leaf of phanerogamic plants, by Herr Fankhauser.—On the principal laws of growth in Florideæ, by the same.—On the formation of the stem in *Lepas anatifera*, by Dr. Lang.—On some luminous bacteria, by Dr. M. Pertz.—Various notes on electrical instruments, by Herr Rothen.—On the soda efflorescences in the Ganges districts, by Prof. Schwarzenbach.—On the geology of Kerguelen's Land, by Prof. Th. Studer.—On deep-water siphonophora, by the same.—On the coloration of the retina, by Dr. A. Valentin.—On some preparations preventing fermentation, and their applicability for the conservation of food.

THE *Giornale di Scienze naturali ed economiche* (Palermo, 1878, vol. xiii.) contains the following papers:—On the cornea of osseous fishes; contribution to the morphology of the eye of vertebrates, by Dr. C. Emery.—On the solar spots observed at Palermo in 1877 and the first three months of 1878, and on the frequency of the vapours of iron and magnesium at the solar surface, by P. Tacchini.—Enumeration and synonyms of the conchyfera of the Mediterranean, by the Marchese di Monterosato.—On the fossils of the crystalline limestone of the Casale and Bellampo Mountains in the province of Palermo, by Prof. G. G. Gemmellaro.

Reale Istituto Lombardo di Scienze e Lettere, Rendiconti, vol. xii. fasc. viii.—Mechanical demonstration of the second principle of thermodynamics, by S. Crotte.—On functions whose first derivatives belong to the class zero, by Prof. Ascoli.—Imaginary plane of linear complex and its intersections, by S. Aschieri.

Fasc. ix.—Prophylaxis of the plague, by Dr. Zucchi.—Researches on the electric conductivity of carbon, by Prof. Ferrini.—On the product of the more integrable and finite functions, by Prof. Ascoli.

SOCIETIES AND ACADEMIES

LONDON

Mathematical Society, June 12.—C. W. Merrifield, F.R.S., president, in the chair.—Mr. R. C. Rowe was proposed for election.—The following communications were made:—Notes on the reduction of a system of forces; and on plane curves, by Mr. J. J. Walker.—Notes on determinants of *n* dimensions, by Mr. Lloyd Tanner.—Curves for the inscription of a regular nonagon and undecagon in a circle, by the Rev. Dr. Freeth.—On Clifford's graphs and on the twenty-one co-ordinates of a conic in space, by Dr. Spottiswoode, P.R.S.—Two geometrical notes, by Prof. H. J. S. Smith, F.R.S.

Chemical Society, June 5.—Mr. Warren De La Rue, president, in the chair.—It was announced that a ballot for the election of Fellows would be held at the next meeting (June 19).—The following papers were read:—A contribution to the theory of fractional distillation, by T. E. Thorpe. The author has observed that of a mixture of equal volumes of carbon tetrachloride, boiling point 76°·6, and of methyl alcohol, boiling-point 65°·2, 46·5 per cent. of the whole distils over at 55°·6–55°·9, 10° lower than the boiling point of its most volatile constituent.—Preliminary note on the action of organo-zinc compounds on quinones, by F. R. Japp. The author has studied the action of zinc ethyl on phenanthrene quinone and obtained a substance crystallising in faintly-yellowish plates having the composition $C_{16}H_{14}O_2C_2H_6O$; he hopes by these reactions to distinguish quinones from double ketones.—Third report to the Chemical Society on researches on some points in chemical dynamics, by Dr. Wright, Messrs. Luff and Rennie. This is a lengthy paper in which the action of carbonic oxide and hydrogen on a uniform weight of copper oxide has been studied at various temperatures; the results are plotted out in numerous curves; in all cases carbonic oxide reduces more quickly or at a lower temperature than hydrogen.—On fractional distillation, by F. D. Brown. The author has studied with great care the distillation of mixtures of benzene and carbon disulphide.—On chlorstannic acid, by J. W. Mallet. A bottle containing a strong solution of stannous chloride after standing for a year deposited a transparent jelly-like substance which proved to be SnO_2HCl. Soda and ammonia salts were obtained.—On indigopurpurin and indirubin, by E. Schunck.

Baeyer and Emmerling obtained a red-colouring matter from isatin, which they named indigopurpurin; this is identical with indirubin obtained by the author from indican. The author considers that the name indigopurpurin should be abolished.

Physical Society, May 24.—Prof. W. G. Adams in the chair.—New Members: Mr. Sedley Taylor, M.A., and Mr. Walter Emmott, A.S.T.E.—Mr. W. J. Wilson exhibited a new harmonograph and figures drawn by it. The figures drawn by prior harmonographs are all more or less imperfect owing to loss of motion in the pendulums actuating the marking pen; and Mr. Wilson therefore designed a new harmonograph which not only gives perfect figures but admits of the phase of either of the two compounded motions being decreased by a known amount. In this instrument toothed wheels take the place of pendulums, the ratio of the teeth giving the ratio of the periods of the motions. By employing the device of an intermediate wheel gearing with two others, and arranging two or more wheels on the intermediate axle, a great variety of phase can be obtained for each motion. An ingenious adjustment by means of a movable nut allows the phase of either or both motions to be altered to a known extent, and thus an endless variety of figures can be obtained. As in other harmonographs a writing-table on which the paper is placed, and an aniline glass pen, are used. Several of the figures done also on glass were thrown on the screen, the stereoscopic effect being very apparent. In reply to a query Mr. Wilson said that he had adapted some of the figures to the stereoscope.—Prof. Hughes explained his new induction balance and showed some of its principal effects. It is well known that on starting an electric current along a wire adjacent to another wire, an induced current is set up in the second wire in an opposite direction to the first or primary current. In the induction balance two primary circuits or coils are taken, with the same current (interrupted by a microphone acted upon by the ticking of a clock) running through both, and between these is placed a secondary circuit or coil in connection with a telephone. The primary coils are so wound as to oppose each other's induction on the intermediate secondary. There is a point, moreover, between these, where these opposed inductive influences exactly neutralise each other. If the secondary coil be placed there, no induced ticking of the clock can be heard; but if the secondary be displaced to one or other side of this point, the ticking can be heard in the telephone increasing in loudness as the secondary approaches one or other of the primaries. If the distance between the primaries be graduated into a scale, this contrivance becomes a sonometer, since it gives an absolute zero of sound, and degrees of loudness. It is well adapted for measuring the hearing power of the ear. By splitting the secondary coil into two parts and placing each close to its proper primary, so that there are four coils in all arranged in two pairs, the extremes in one primary circuit, and the means in one secondary, the two opposing parts of the balance can be separated from each other, so as not to disturb each other's action, and the balance made very sensitive by the closeness of the primaries and secondaries. Prof. Hughes finds that there is a line or zone of maximum induction midway between each primary and its secondary. If a conductor such as a piece of metal be put in this position it has a maximum disturbing effect on the balance, due probably to the electric currents generated in it by the induction. The effect is apparently proportional to the conductivity of the metal. It requires an exactly similar piece of metal put between the other pair of coils to restore the equilibrium of the balance. A difference of alloy, or of weight between two like coins is at once observed from the imperfect restitution of the balance; base coins are thus also at once detected. Again, it is possible for a person to tell what particular coin or coins are in one part of the balance by trial of the same coins in his part. When plates of non-magnetic metals are held vertical in the balance their disturbing effect is *nil*; iron on the other hand gives its maximum effect on this position, because its magnetic effect overbalances its electrical effect. Two pieces of iron may therefore neutralise each other as cores in an induction coil. Steel is easy to balance compared with soft iron. Zinc disturbs most when placed along the sides of each pair of coils; iron when in centre at a certain length of metal laid along the outsides of the coils produces silence. The maximum line of inductive force is midway between the coils, and there is a line of minimum force at half the thickness of each coil. A metal placed at these lines of minimum force has no disturbing effect on the balance. Pressure applied to small shot, or spongy gold, alters the balance. The effects of stress, heat, magnetism, light, &c., on matter could be determined by the balance. Prof. W. G. Adams believed that one result of Prof. Hughes's experiments will be the determination of the way in which the law of electro-dynamic induction depends on density. He also imagined that the metal when in the maximum line between the coils gathered the lines of force to itself, whereas when on the minimum lines it could not thus divert them. Prof. Ayrton cited the early experiment of Faraday with a sheet of copper oscillating to rest between two opposite magnetic poles. The copper took a long time to stop; but a sheet of iron placed between two like poles was soon stopped owing to its becoming imbued with an opposite polarity, and deflecting the lines of force. He also suggested that the divergence of the results for conductivity of metals got by the induction balance from those got by the Wheatstone balance might be due to that electric inertia suspected by Sir William Thomson. Prof. Guthrie thought that the induction balance pointed to the conclusion that the disturbing effect of a conducting mass applied in this way is proportional to the quantity of electricity generated in it under certain conditions of temperature, &c. The determination of the conductivity of liquids would be a useful application of the balance. Mr. Chandler Roberts gave some results which he had obtained from an examination of certain alloys by means of the induction balance. He had been able to detect a difference of one part in 1,000 in the amount of silver in two shillings of equal weight. He also pointed out that Mathiessen divided alloys into three classes: (1) solidified solutions of one metal in another; (2) solidified solutions of one metal in an allotropic modification of another metal; (3) solidified solutions of allotropic modifications of both metals. For the first class the curve of electric conductivity is a straight line, for the second a parabolic curve, for the third a bent line. Mr. Roberts found that the balance gave the characteristic curve for the first class with an alloy of lead and tin, and for the second with an alloy of gold and silver. With a copper tin alloy, which is a good example of the third class, he found the curve given by the balance to be intermediate between Alfred Risch's curve of density and Mathiessen's curve of conductivity, and considers that the balance is influenced by the density as well as the conductivity of the metal interposed. Prof. Hughes said that as the working of metals appeared to affect their conductivity he was inclined to rely more on the conductivity measurements of the balance than on those of the Wheatstone bridge. By the balance plain pieces of metal were taken, whereas by the bridge wires were mostly taken. He would rather not give any theory yet as to the results obtained from the balance.—Dr. Erck then exhibited his novel pump for lifting solutions out of batteries. It consists of a closed vessel, funnel-like, the stem dipping into mercury, a column of which ascends the latter to a certain height. Two tubes emerge from the cover, one dipping into the liquid, the other opening to the air. By altering the pressure inside the vessel the solution rises to the latter, and can escape from it by trickling through the mercury.

Anthropological Institute, June 18.—Mr. Hyde Clarke, vice-president, in the chair.—The following new Member was announced: Mr. William Wavell, late of the Bengal Civil Service.—A paper was read by Miss A. W. Buckland on some Cornish and Irish prehistoric monuments. The authoress compared the sepulchral and the non-sepulchral monuments existing in the two countries, pointing out the differences between them, as indicating, either that they were erected by different tribes, or at various periods, and calling especial attention to the absence in Cornwall of the round towers, so common in Ireland, as well as of oghams, and those peculiar markings found in the Irish chambered tumuli at New Grange, Dowth, &c., as also in similar monuments in the north of Scotland and in Brittany. These markings are believed by Miss Buckland to represent the tribal or tattoo marks of the Picts or a kindred race, being one of many different tribes brought by tradition from the neighbourhood of the Euxine, a tradition apparently confirmed by the decidedly eastern characters of the jewellery found in Ireland, as well as by the megalithic monuments which can almost all be traced to Eastern Europe, and thence through Western Asia to India. Notwithstanding this apparently common origin, Miss Buckland pointed out that they are almost everywhere arranged in groups suggestive of a difference of race in their constructors, and expressed a hope that some day a map of the world would be constructed showing these groupings, which would be a great help to students of ethnology and archæology.—Mr. C. Pfoundes also read a paper entitled "Some Facts about Japan and its People," and exhibited drawings in illustration of the same.

Entomological Society, June 4.—H. W. Bates, F.L.S., F.Z.S., vice-president, in the chair.—The following elections took place:—Mr. J. Walhouse, F.R.A.S., Maida Vale, as an Ordinary Member, Señor Antonio Augusto de Carvatho Monteiro, Lisbon, as a Foreign Member, and Mr. C. H. Goodman, Lesness Heath, as a Subscriber.—Mr. McLachlan called attention to a notice lately published by M. F. A. Forel, concerning certain sculptured markings on cretaceous pebbles from the shores of Lake Leman, in which the author has come to the conclusion that the markings were mainly due to the action of larvæ of trichoptera, which formed galleries on the surface. Mr. McLachlan exhibited plaster casts of two small blocks, one of Jurassic limestone, the other of ordinary white chalk which had been placed in the lake by M. Forel for some months, and which showed markings that apparently confirmed the theory that such were due to the agency of trichopterous larvæ, of which some specimens in alcohol were also exhibited.—Mr. J. S. Baly communicated a paper entitled "An attempt to point out the differential characters of some closely allied species of *Chrysomela*, chiefly those contained in Suffrian's 11th group; also descriptions of some hitherto uncharacterised forms belonging to the same and other genera of the family."—The following papers were communicated by Prof. Westwood:—"A decade of new Cetoniidæ," and "On some unusual monstrous insects."—Mr. W. L. Distant read a paper entitled "Contributions to our knowledge of the hemipterous fauna of Madagascar."—Sir Sydney Saunders communicated some notes received from M. Jules Lichtenstein, describing the metamorphoses of the blister-beetle *Cantharis versicatoria*, which he had recently succeeded in rearing from the egg.—Mr. Meldola communicated a translation of a paper by Dr. Fritz Müller, recently published in *Kosmos*, entitled "Ituna and Thyridia; a Remarkable Case of Mimicry in Butterflies."

Victoria (Philosophical) Institute, June 16.—The president, the Earl of Shaftesbury, in the chair.—Capt. F. Petrie (the Honorary Secretary) read the report. It appeared that the Society had lost twenty by death, and twelve members and eighteen associates by resignation, since the last annual meeting, but that eighty-six new members had joined in that time. The total number of members is now 785. The address was delivered by Dr. Radcliffe, and took the form of an inquiry into the present position of physical science.

EDINBURGH

Royal Society, June 16.—Prof. Maclagan, vice-president, in the chair.—The following communications were read:—Atomicity or valence of elementary atoms: is it constant or variable? by Prof. Crum Brown.—On the action of heat on salts of primethyl-sulphine, part iv., by Prof. Crum Brown and J. Adrian Blaikie, D.Sc.—Comparison of the salts of methyl-diethyl-sulphine, and of ethyl-methyl-ethyl-sulphine, by Prof. Crum Brown and J. Adrian Blaikie, D.Sc.—On the bursting of fire-arms when the muzzle is closed by snow, earth, grass, &c., by Prof. George Forbes.—On some new bases of the leucoline series, part iii., by G. Carr Robinson and W. L. Goodwin.

BOSTON (U.S.A.)

American Academy of Arts and Sciences, May 14.—Hon. Charles Francis Adams in the chair.—Dr. H. P. Bowditch presented a new form of plethysmograph differing from those of Mosso and von Basch in the method adopted for securing a constant level of the fluid in the receptacle connected with the apparatus which contained the body whose changing volume was to be measured. The method consisted in suspending the receptacle (a large sized test tube) to a delicate spiral steel spring of which the length and strength were so adjusted that the weight of the fluid flowing into the test tube caused an elongation of the spring precisely equal to the rise of the fluid in the test tube itself. Thus the absolute level of the fluid in the receptacle remained unaltered, and a constant pressure was maintained upon the surface of the organ to be measured. An index attached to the lower end of the spring recorded upon a revolving cylinder covered with smoked paper the flow of the fluid into and out of the receptacle.—Mr. N. D. C. Hodges gave two new proofs of the dimensions of molecules, one based upon the properties of water and aqueous vapour, the other upon superficial tension and considerations of the depth of the superficial layer of molecules upon sheets of platinum.—Prof. Pickering exhibited a new form of photometer for measuring the light of a nebula or comet, by comparison with a star thrown out of focus. The method employed eliminated the effects of moonlight or twilight. He also proposed to denote the light of these bodies in stellar magnitudes. Thus a portion of a nebula would be of the twelfth magnitude, if of the same brightness as a twelfth-magnitude star spread over a circle one minute in diameter.—Prof. John Trowbridge presented two contributions from the Physical Laboratory of Harvard College, one on the vibration of elliptical plates, and one on a new method of studying wave-motion and vibrations on the surface of mercury. The mercury is covered with a very thin film of lycopodium dust, and is illuminated by the electric spark produced by breaking a circuit on the surface of the mercury.—Prof. C. Loring Jackson and Mr. J. Fleming White announced a new synthesis of anthracene.—Prof. Asa Gray presented the characters of new species of plants from Mexico, collected by Dr. E. Palmer and Dr. C. C. Parry.—Prof. Wolcott Gibbs, a research on complex inorganic acids; and Mr. Sereno Watson, a revision of the North American liliaceæ and descriptions of some new species of other orders.

PARIS

Academy of Sciences, June 9.—M. Daubrée, president.—The following papers were read:—Chronometric observatories for the merchant marine, by M. Faye.—On the spherical regulating spiral of chronometers, by M. Phillips.—On the bases derived from aldehyde-ammonia, by M. Ad. Wurtz.—Determination of the height of the mercury in the barometer under the equator; amplitude of diurnal barometric variations at various stations in the Cordilleras, by M. Boussingault.—Increase of albumenoid matters in the saliva of those having albumenuria, by M. Vulpian.—On the spectrum of nitrate of didymium, by MM. Laurence Smith and Lecoq de Boisbaudran.—On the spectrum of nitrate of erbium, by M. Lecoq de Boisbraudran.—Observations made during the voyage of the frigate *La Magicienne*, by Admiral Serres.—The following papers were among the correspondence:—Observations of Comet II., 1867, made at the Observatory of Florence (Arcetri), by M. Tempel.—Transformation of a pencil of normals, by M. A. Mannheim.—On the use of elliptic functions in the theory of the plane quadrilateral, by M. G. Darboux.—On developments in series whose terms are Laplace's functions Y_n, by M. A. de St. Germain.—On the laws of dispersion, by M. Mouton.—On Stokes's law, by M. S. Lamansky.—On the absorption spectra of alizarin and some colouring-matters derived from it, by M. A. Rosenthal.—On the *verglas* of January 22, by M. de Tastes.—On the dissociation of ammonium sulphide, by MM. R. Engel and Mortessier.—Action of the vapour of water on carbonic oxide in presence of a red hot platinum wire, by M. J. Coquillion. On some derivatives of methyleugenol, by M. Wassermann.—On an isomer of angelic acid, dimethyl-acrylic acid, by M. E. Duvillier.—On the action of phenate of sodium in bacteriemic frogs, by M. Bacchi.—Hematic lesions in chlorosis, the serious anemia named progressive, and the anemia of nephritis, by M. Quinquand.—Researches on the localisation of arsenic in the brain, by MM. O. Caillol de Poncy and Ch. Livon.—Rectification in a communication of March 17 last, by M. Feltz.—Erratic blocks of the Valley of Lys (Haute-Garonne), by M. Gourdon.—Fall of meteorites on May 10, 1879, in Emmet County, Iowa, U.S., by Prof. Hinrichs.

CONTENTS

THURSDAY, JUNE 26, 1879

HISTORICAL SUN-DARKENINGS

NOT a few persons appear to have been much exercised by a prognostication emanating from an American source, whereby the public are forewarned of an approaching period of sun-darkening to extend over several days. History does record instances in which the sun has been abnormally obscured or its light paled to such an extent that stars have come into view in the daytime, and Erman, Humboldt, and other writers have brought these occasions into prominent notice, the former in connection with the presumed passage of dense meteoric streams between the earth and the sun. The earliest mention of such a phenomenon appears to be in the year B.C. 44, about the time of the death of Julius Cæsar, when we read in Plutarch and Dio Cassius that the sun was paler than usual for a whole year, and gave less heat, the air continuing cold and misty. The darkness for two hours on August 22, A.D. 358, appears to have preceded the great earthquake of Nicomedia. Two years later in all the eastern provinces of the Roman Empire we are told there was "caligo a primo auroræ exortu adusque meridiem," and the stars were seen, the further description being rather applicable to a total solar eclipse; but neither the eclipse of March 4, 360, nor that of August 28, would be visible in those parts. Again, when Alaric appeared before Rome, the darkness was such that stars were seen in the daytime (Schnurrer, "Chronik der Seuchen"). Following the *Tablettes Chronologiques* of the Abbé Lenglet Dufresnoy, Alaric invested Rome A.D. 409, and became master of the city on August 24, 410; there was a visible eclipse of the sun on June 18 of the latter year, therefore while the siege was in progress; but on calculating the circumstances under which it would be seen at Rome, introducing the latest lunar elements, it appears that little more than half the sun's disk would be covered at the greatest phase about 2h. 40m. P.M., and no sensible diminution of sun-light would be occasioned by the eclipse. In 536, 567, and 626 we find mention of long periods of diminished sun-light. Schnurrer records that in 733, a year after the Saracens had been driven back beyond the Pyrenees, consequent on their defeat at Tours, "the sun darkened in an alarming manner on August 19; there appeared to be no eclipse by the moon, but rather an interruption from some meteoric substance." There was an eclipse of the sun, annular but nearly total, on the morning of August 14; it is mentioned in the Saxon Chronicle, which tells us "the sun's disk was like a black shield." The near coincidence of dates suggests in this case a connection between the darkness and the eclipse. In 934, according to a Portuguese historian, the sun lost its ordinary light for several months, and this is followed by the doubtful statement that an opening in the sky seemed to take place, with many flashes of lightning, and the full blaze of sunshine was suddenly restored. In 1091, on September 29, not 21, as given in some of the translations of Humboldt's *Cosmos*, Schnurrer relates that there was a darkening of the sun which lasted three hours, and after which it had a peculiar colour which occasioned great alarm. In another place we read: "Fuit eclipsis Solis 11 Kal. Octob. fere tres horas: Sol circa meridiem dire nigrescebat": there was no visible eclipse at this time, and the November eclipse was central only in the southern parts of the earth. A century later, or in June, 1191, according to Schnurrer, the sun was again darkened, with certain attendant effects upon nature: here the cause is easily found; on June 23 there was a total eclipse, in which the moon's shadow traversed the continent of Europe from Holland to the Crimea; the eclipse was total in this country between the coasts of Cumberland and Yorkshire. Erman refers to a sun-darkening on February 12, 1106, which was accompanied by meteors, and we read in the cometographies that on the 4th, or, according to others, on the 5th, of February in this year a star was seen from the third to the ninth hour of the day, which was distant from the sun "only a foot and a half." Matthew Paris and Matthew of Westminster term this star a comet, and we may take it to have been the same which, later in the same month, was observed in China under the sign Pisces, and which at one time was supposed to have been identical with the great comet of 1680; this body, however, would not appear to have been sufficiently near the earth as, even on the assumption of a denser constitution than usual with comets, to account for a diminution of the solar rays, by its intervention. On the last day of February, 1206, according to a Spanish writer, there was complete darkness for six hours. In 1241, "five months after the Mongol battle of Leignitz," the sun was so obscured, and the darkness became so great, that the stars were seen at the ninth hour about Michaelmas. In this case, again, the darkness referred to was undoubtedly due to the total eclipse on October 6, of which Prof. Schiaparelli has collected a full account from the Italian writers. Lastly, in 1547, from April 23-25, Kepler relates on the authority of Gemma, "the sun appeared as though suffused with blood, and many stars were visible at noon-day." Schnurrer thought this phenomenon was what the Germans call an "Hohenrauch," notwithstanding the visibility of stars.

From the above brief summary of what have been considered abnormal sun-darkenings, we see that in several cases the diminution of light has been due to the ordinary effects of a total eclipse, while it is clear that there are no grounds in the historical evidence for any prediction of a period of darkness. The nervous in these matters, and it would really appear that such exist, may take consolation therefrom.

J. R. HIND

SCIENCE AND AGRICULTURE

BRITISH agriculture, in most of its aspects, will come into prominent notice next week. The great show at Kilburn, coming as it does just now at a time of great depression for farming at home, ought to teach us some useful lessons. It should tell us that the days of rule of thumb, the days in which we did as our fathers did are over. New means, new methods, new materials, new economies, new crops, must be associated with wider views of what the world wants and with more precise knowledge of what our little islands can best supply.

If we study soils, manures, crops, live stock, implements, the after-treatment of farm produce, or the instruction of agriculturists and of labourers—in every direction we shall learn how beneficial has been, and may still be,

the influence of the scientific method upon the agricultural art.

Anlaysis of soils has not answered the questions put by its means exactly as we expected. But it has frequently shown us why, through excess or defect of some ingredient, certain lands were barren, and it has taught us how cheaply and thoroughly to remedy their sterility. Excess of decaying organic matter, of soluble salts, or the presence of ferrous salts, or of iron pyrites, these have been recognised amongst the curable ills of our soils. What is known as the *coagulation* of clay is now understood, so that we can often bring it about and thus render heavy lands workable at our will. The relations between the fungi inimical to our cultivated plants and the constituents of our soils being known we can now fight more hopefully against blight and mildew. What kind of exhaustion of soil is to be feared and how it can be remedied is now within our knowledge.

The development of the industry of artificial manures has been a very marked feature of the whole period of forty years during which our great Agricultural Society has been in existence. Farmyard manure has been relegated to its true place—no mean one, but one which has no longer the importance once attached to it. As 100 tons of ordinary dung and litter do not contain more than 1 ton (often less) of real manurial substance—potash, nitrogen, phosphorus pentoxide—one hundredweight of guano may frequently replace with advantage the usual dressing of farmyard manure applied to an acre. But while chemistry has searched out the constituents of manures, and recognised and determined the elements of fertility scattered in minerals and guano and waste products throughout the world, and shown how to bring all plant food into available forms, it has had also to carry on a perpetual warfare with the bands of adulterators, perfecting its methods of detecting the falsification of the materials which it has itself introduced; for manures are difficult to test by mere inspection, often being merely "dirts with a strong smell."

The improvement of existing varieties of plants by artificial selection has been carried to great perfection in many instances—the sugar-beet and wheat being notable examples. The introduction and improvement of new plants, both for cattle food and for the sustenance of man, is a work in which much remains to be done. Especially should attention be directed to those crops upon which lesser, but in many cases more, remunerative industries than mere corn-growing may be founded. Plants yielding products useful in medicine, dyeing, and perfumery, should not be neglected. Some districts on the Continent, such as the neighbourhood of Florence, have been immensely benefited in every way by the introduction of minor crops with their attendant industries; similar successes may be repeated where skill and capital are available, climate and soil being of course taken into account.

Of improvement in the breeds of horses, cattle, sheep, and pigs, nowhere can be found better illustrations than in England: we shall soon see how much our neighbours and friends abroad have gained from our work in this direction. In agricultural machinery and implements the same statement may be made with still greater emphasis: it is indeed curious to note how in every text-book of agriculture, in every farmer's journal, and rural advertisement published in France, Germany, Italy, and in most other countries both of the Old World and the New, the familiar names of Howard, and Fowler, and Cambridge, and Aveling, meet us on plough, and roller, and harrow, and engine. Perhaps in the after-treatment of some kinds of ordinary farm produce, we have been behind our Continental neighbours and American cousins, but we are beginning to appreciate better the aids that science can render to cheese and butter-making, and to the preparation of mill-products from wheat. The critical study of milk and dairy processes is securing the attention of dairy-farmers in England; while such an invention as Wegmann's porcelain cylinder for milling wheat has revolutionised the old grinding process already.

Of progress in the agricultural education either of farmers or farm-labourers, we have little to boast. Our solitary Agricultural College at Cirencester has been ever and anon paralysed by mismanagement; while its charges are too high, owing to the absence of any endowment, for its instruction to be accessible to the sons of ordinary farmers. Agricultural newspapers are neither as cheap nor always as instructive as they should be; the education in our elementary schools has hardly yet acquired that agricultural bias which in rural districts might be so advantageously given to it. Still the Science and Art Department has begun a good work by instituting its examination in the principles of agriculture, although its syllabus presupposes that the examinees will have been been fed on far richer and more varied stores of learning than are yet at their disposal.

This Kilburn Show will then direct our attention to a multiform subject of the greatest national importance at the present crisis. We shall hope to learn much from the exhibits in the eight miles of shedding arranged in due order over more than 100 acres of ground, and to be rewarded with over 13,000*l.* in prizes.

THE ELECTRIC LIGHT

THE Committee of the House of Commons appointed to inquire into the value of the electric light has completed its labours and has issued its report. There is no doubt that the evidence given before it, when published, will be very useful, and that the report itself is a careful digest of the facts elicited, but it is questionable whether the results of the inquiry, or the conclusions of the Committee, will satisfy any one. Our readers will find in it nothing new. Gas engineers will find in it their extermination calmly contemplated. The gas manufacturer is told that he has nothing whatever to do with electricity. Gas, and nothing but gas, is his ware. Though he was incorporated to illuminate a city with the then best known illuminant, he is not to touch a newer illuminant because he will check the development of the fresh source of light, and his present mode of production is quite different to that required for the new commodity. It is as though a wine merchant who had a large sale of sherry were not allowed to sell beer, or a dairyman were not allowed to sell asses' milk because he only kept cows. The enunciation of such a proposition in a Parliamentary Report is sad. Worse than all, municipal

authorities are advised that they can ruin all the gas interests without the distribution of any compensation whatever. Surely the enormous capital sunk by the public in gas enterprise deserves some consideration from its representatives in Parliament assembled. Are our vestries and corporations so immaculate that they are to have entire control of our supplies of water and of light? Why not give them the supply of food and of heat? The line must be drawn somewhere, and it is well that Parliament should hesitate in the complacency with which it now thrusts on irresponsible communities the distribution of vital necessaries.

The only sphere in which electricity has made itself useful and practical as an illuminant is in our lighthouses, and though it is eminently adapted for nautical purposes, as ordinary ships' lights, or to illuminate the sails of a ship, the Report is silent on the point and on the absurd restrictions which have been placed by the Board of Trade on its use at sea.

The statement that the energy of one-horse power when converted into gas-light only gives 12-candle power, and into electric light 1,600 candle power is startling if true. Without the evidence before us on which this statement is made we cannot well contravene it, but it seems based on some fallacy. We remember seeing somewhere, but cannot recall where, a somewhat similar estimate, but it was based on the assumption that the whole of the coal was consumed in producing gas, and no allowance whatever was made for the coke, tar, and other products of distillation. Is it so in this instance? Though 3 lbs. of coal consumed in one way may give one horse-power, and in another way 12-candle light, it by no means follows that one-horse power is equivalent to 12-candle gas-light—for in the case of gas we do not know the remanent energy.

The report fully confirms the opinion we have frequently expressed that the electric light sensation was due to a scare and not to any real progress or new discovery made. The transmission of power for mechanical purposes is foreign to the inquiry, and the suggestion that currents used by day for mechanical purposes can be used at night for illuminating purposes assumes what we only wish were true, that there is no mechanical work done in England in hours of darkness.

The general conclusion arrived at is that we can do no more with the electric light at present, but that we must do nothing to restrict its development. We did not require a Parliamentary Committee to tell us that.

INDIAN GEOLOGY

A Manual of the Geology of India. By H. B. Medlicott, M.A., and W. T. Blanford, F.R.S. Published by Order of the Government of India. (Calcutta, 1879.)

THE appearance of this long-promised work marks an epoch in the history of Indian science. In two moderate octavo volumes (paged as one) and the map which accompanies them, we have placed before us, in an attractive and convenient form, the matured conclusions of upwards of thirty years' systematic survey of the geology of our Indian possessions; and now, for the first time, the geological structure of India, or, at least, its leading facts, may be mastered by the student at no greater cost of labour than is involved in a few days' study of a well-arranged and thoroughly trustworthy manual.

We are reminded almost in the opening words of the preface, how many of those who have contributed to the researches on which this work is based, have now passed from among us. Stoliczka, J. G. Medlicott, the two Oldhams, Williams, and Loftus are only a few of the better known names among the many that for a longer or shorter time have been borne on the rolls of the Indian "Geological Survey," whose bearers lie in Indian graveyards, or beneath some modest tomb on the out-skirts of an Indian village, or who finally have returned with shattered health to the land of their birth, only to bring to a close among their friends the last few enfeebled months of their career. Of the earlier labourers in the field, of those who witnessed the birth of the "Geological Survey of India," and who three-and-twenty years ago wielded their hammers in breaking open the secrets of Indian rocks, but three still remain members of the Survey Staff, and to two of these surviving members whose names stand at the head of our article, we are indebted for the present masterly summary of the common labours of all.

The contributions of the two authors to the joint work are distinct, and in point of magnitude unequal. To Mr. W. T. Blanford has fallen the lion's share of the labour. Of the thirty chapters which (including the introduction) make up the work, Mr. Medlicott contributes ten, viz., those on the metamorphic and azoic rocks of the peninsula, and those on the geology of the Himálaya east of the Jhelum, and on Assam. The remaining twenty chapters, including the introduction, which deal with all the fossiliferous and neozoic rocks of the peninsula, the geology of Sind, the Punjab and Burma, and the Sivalik fauna generally, are the work of Mr. W. T. Blanford. The map,[1] which is printed in colours and is on the scale of sixty-four miles to the inch, has been compiled in the office of the Geological Survey, from materials in part unpublished. It professes to be only a preliminary sketch map, and three small tracts in the peninsula, the greater part of the Bikanir Desert and Guzerat, the Nepalese Himálaya, and Arakan and the adjoining hill tracts are left uncoloured. But with these exceptions it exhibits in as detailed a form as the scale admits of, and with unquestionable accuracy, the extent and boundaries of the several formations, classed as Alluvium, Upper and Lower Tertiary, Cretaceous, Jurassic, Triassic, Carboniferous, Silurian, Submetamorphic, Metamorphic, Granitic, Volcanic; and in the peninsular area, Upper and Lower Gondwána, and Vindhyan, the meaning of which unfamiliar and special classification we shall presently have occasion to notice.

The subdivision of the whole region into a peninsular and an extra-peninsular area is one of fundamental importance, and, as such, is treated in the arrangement of the manual. Geographically, the two areas are separated by the broad unbroken alluvial plain which stretches along the foot of the mountain zone from the mouths of the Indus to those of the Ganges; and geologically both in

[1] A copy of this map was sent for exhibition to the Great Paris Exhibition last year, but was probably seen by few. In fact, it was suspended in the office room of the Indian department, avowedly for want of room. Meanwhile a conspicuous case in the centre of the transept was devoted to the exhibition of Indian pickles.

history and structure, they present many strongly-contrasted features. In the words of one of the writers, "This [the extra-peninsular area] is geologically an intrinsic portion of the Asiatic continent, whilst peninsular India is not." For many years, indeed, it seemed that there was scarcely any stratigraphical link between the richly fossiliferous formations of Sind, the Salt Range, and the Kumaon Himálaya on the one hand, and on the other, the plant-bearing or azoic shales, and thick-bedded sandstones, described by Newbold, Williams, Voysey, Hislop, and others, which, with volcanic and metamorphic rocks, make up the greater part of the peninsula. While, with the exception of the later Himalayan and Sind tertiaries, the former are in the main of marine origin, a large portion of the latter are the characteristic deposits of fresh water; and, as regards the less ancient and fossiliferous formations, the apparently conflicting indications of age afforded by their fossil remains left it long impossible not merely to correlate them with any recognised members of the extra-peninsular formations, but even to assign to them with any confidence an approximate place in the general scale of geological sequence. Nor can this problem even now be considered as fully solved. But the scraps of evidence which, one by one, have been brought to light in the continued progress of the Survey have greatly simplified it, and this evidence is ably analysed and summed up in the first volume of the manual. The plant-bearing formations of the Peninsula are now regarded as one great system, to which the name Gondwána has been given, subdivided into an upper and lower series, and it represents the deposits of an ancient system of river valleys, dating from Permian and lasting to Tithonian times. The lesson in geological reasoning, inculcated by the geology of these rocks, is one that deserves to be carefully pondered, and in illustration of the difficulties which it presents, we will quote one or two passages from the fifth chapter of the Manual. To render the description more clear to the general reader we preface them with an excerpt from the tabular synopsis of the Gondwána formations at p. 108, exhibiting the accepted stratigraphical relations of the different groups referred to. It includes four only of the eight regions summarised in the original table.

	General Sequence.	Satpúra Region.	Godaveri Valley.	East Coast Region.	Cutch.
Upper Gondwána.	Cutch and Jabalpur	—	Chikiála	Tripelty	Umia
		Jabalpur		Sattavedu (?) ...	Katrol
	Rajmahal and Mahadeva	Bagra ...	Kota-Maléri ...	Ragavapuram and Sripermatur	—
		Denwa..		Golapilli	—
		Pachmari	—	—	—
Lower Gondwána.	Panchet ...	Almod(?)	Kámthi (including Mangli)	—	—
	Damúda ...	Bijori ...		—	—
		Motur ...		—	—
		Barákar.	Barákar	—	—
	Talchir ...	—	—	—	—
		Talchir..	Talchir	—	—

"[Dr. Feistmantel] ascribes to the whole series an age ranging from Lower Trias or Bunter (Talchír and Damúda) to Middle Jurassic or Bathonian (Jabalpúr and Umia). His determinations, however, being founded exclusively on a comparison of the Gondwána fossil plants with those of European formations, are very frequently opposed by other fossil evidence. The Umia beds of Cutch, for instance, the flora of which is considered by Dr. Feistmantel of the same age as that of the Jabalpúr group, which is the highest Gondwána subdivision, contains several plants found also in the Lower Oolites of Yorkshire, but the Cephalopoda of the marine beds, which immediately underlie the Umia plant beds, and are, to some extent, interstratified, have been shown by Dr. Waagen to be uppermost Oolitic (Portland and Tithonian) forms; and to be separated by two distinct groups of beds, each with a well-marked fauna, from the underlying strata, in which lower Oolitic Cephalopoda occur. In the Damúdas and their representatives, on the other hand, although a few fossil plants are allied to Triassic species, several of the most abundant and characteristic forms are unknown in the Trias of Europe, but are represented by the same or nearly allied plants in the coal measures of Australia, the lower portion of which is certainly of Carboniferous age." Again, "As an example of the difficulties presented in the present state of our knowledge by the contradictory evidence afforded by the fossils of one group, the case of the Kota-Maléri beds may be cited. The Kota beds consist of limestone, and contain remains of fish which have a liassic facies. The Maléri (or Malédi) beds have yielded two reptiles, *Hyperodapedon* and *Parasuchus*, and a fish, *Ceratodus*, all of which are closely allied to European triassic forms. In these Maléri beds some plants have been obtained common to the Jabalpúr and Sripermatur groups, the flora of the former of which has been shown to be in part identical with that of the Umia group of Cutch. The singularly contradictory evidence of age afforded by this Umia flora has already been mentioned. The Kota beds with their liassic fish have now been shown to be so closely connected with the Maléri clays and sandstones, containing triassic reptiles and fish and jurassic plants, that both are classed in the same group."

The conclusion which Mr. Blanford draws from this apparently conflicting evidence is the following:—

"Assuming that the association of similar marine forms in the rocks of distant countries—for instance in the Carboniferous limestone of Europe, the Punjab in India, and Australia,—implies that the rocks are of contemporaneous or nearly contemporaneous origin, the remarkable combination of fossils in the Kota-Maléri beds seems to show that, in mesozoic times, there was a wider diversity in the forms of terrestial life inhabiting distant regions at any given period than there was in the faunas of the surrounding seas. This view is in accordance with the very similar conditions now found prevailing upon the earth's surface, there being a much greater difference between the terrestrial faunas and floras of Africa, Australia, and America, for instance, than there is between the animals inhabiting the Atlantic, Indian, and Pacific Oceans. . . . . There appear, in short, good reasons for believing that the terrestrial area of the world was divided into zoological and botanical regions in past times as it is at present, and the fauna and flora of India may have differed at times, more from those then existing in distant countries, than from the animals or plants which prevailed in the same distant regions at a different geological epoch."

At the very base of the Gondwána system occurs that remarkable bed of silt containing transported boulders which is held by the authors, and we believe we may now say by all members of the Geological Survey of India, to afford evidence of the action of ice, probably ground ice; and it is not a little striking that the most conclusive evidence of this agency, viz., polished and grooved boulders resting on a surface of limestone equally polished and scored, was met with in latitude 20°, at an elevation of about 700 feet above the sea. The resemblance of this bed to that at the base of the Karoo formation of South

Africa, and indeed the palæontological and physical parallelism of the Karoo and Gondwána formations generally is now well known.

The peninsular area affords no instance of any fossiliferous rock of older date than the Gondwána system. But a large area to the north of Madras, another in Chhatisgarh, east of Nagpur, a third very extensive tract in Bundelkhand and Malwa, partly covered by trap, but still exposed over a surface of 40,000 square miles, and some smaller tracts in the valleys of the Kishna and Bhima rivers are occupied by a massive and quite unaltered series of sandstones, limestones, and shales of great thickness which have received the name of the Vindhyan System. From the fact that both in Bundelkhand and Hyderabad diamonds are found imbedded in these rocks, the name "diamond sandstone" was given by Capt. Newbold to a portion of these rocks, but the name was erroneously extended to the much later sandstones of the Gondwána formation, an error only cleared up by the labours of the Geological Survey. Beyond the fact that the Vindhyan system cannot be newer than Lower Palæozoic, nothing whatever is known of its age. Repeated search in the limestones and shales, however promising in appearance, has revealed no trace of any fossil organism, and it is impossible to correlate them with any group of rocks in the extra-Peninsular area, or, indeed, elsewhere. Below and older than these again, are two, or perhaps more, series of submetamorphic rocks, which, under various local names, have been mapped and described in many parts of the Peninsula, and all rest on the fundamental gneiss, which, whether of one or many ages, is everywhere the oldest rock, and is still exposed over nearly half the area.

The only remaining extensive formation of the Peninsula is the great Deccan trap-flow, the most extensive volcanic formation in the world. The age of this formation is now definitely fixed as Upper Cretaceous. Except in the neighbourhood of Bombay, where it dips with a gentle inclination beneath the sea, the successive flows are perfectly horizontal, occasionally interbedded with thin deposits of freshwater origin, and at one place, near Rajahmahendri, with an estuarine deposit. The area still covered by this formation is estimated at little less than 200,000 miles, and there are proofs of its former existence throughout nearly ten degrees of latitude and sixteen of longitude. For the discussion of the many interesting problems presented by this great manifestation of volcanic energy, we must refer the reader to the original work.

In passing from peninsular India to the encircling mountains we pass from an old continent to a new one, from a relic of a mesozoic land area, to the Asia of tertiary and post-tertiary times, and from a region where prolonged denudation has long since obliterated all but the merest traces of original mountain structure, leaving water-worn bosses of hard crystalline rock-cores or scarped slopes and sculptured platforms of horizontal trap or sandstone, to one where the latest deposits of tertiary times are so contorted and faulted as to render the task of disentangling the geological relations of the formations sometimes one of extreme difficulty.

The history of the Himálayan system, which, in addition to the Himálaya proper, includes the Indus ranges and those of the Burmese peninsula, begins in eocene times. It is considered by Mr. Medlicott that the very ancient slaty rocks which now form the greater part of the mountain mass south of the snowy range, and which he designates as the "Lower Himálaya," had undergone no contortion prior to the nummulitic period; and that immediately before its partial depression beneath the nummulitic sea, this area had been long exposed to denudation as "part of a land of doubtful configuration." It is still somewhat doubtful to what age are to be assigned the slaty formations here spoken of. As yet they have yielded no recognisable fossil remains, and they present no such similarity of character to the formations north of the main axis in Zanskar and Hundes, where rocks rich in fossil organisms have been described by Gérard, Strachey, Stoliczka, and others, as to allow of more than a speculative correlation. A recent observation of Mr. Lydekker's in the Pir Panjál range of Kashmir, throws however some little light on the question. The rocks of the slaty series extend in a north-west direction to the Pir Panjál range, and a limestone which there occurs at the top of the series, and appears to be identical with the Krol limestone (also the highest member) of the series near Simla, has been identified by Mr. Lydekker as Carboniferous. From this it would appear that rocks of mesozoic age are completely absent from the Lower Himálaya, and are restricted to certain areas north of the snowy range, and in the extreme north-west to certain parts of Kashmir, and we may add, the western extremity of the Salt Range.

Only in the Eastern Himálaya, viz., at the base of the Sikkim hills, have we any *indubitable* representative of the characteristic fresh water formations of the peninsula. In 1849, Dr. (now Sir Joseph) Hooker, detected some of the well-known fossil plants of the Bengal coal-bearing (Dámúda) formation in certain shaley beds exposed at the foot of the hills near Pankabári, on the road to Darjiling, and this observation, subsequently followed up by Mr. W. T. Blanford, and more recently by Mr. Mallet, has led to the recognition of a band of Lower Gondwána rocks, occupying a narrow zone between the tertiary sandstones of the Terai and the talcose slates of the outer hills. The connection between the Eastern and Western Himálaya remains, however, to be traced out, the intervening kingdom of Nipál being unfortunately closed by the suspicious jealousy of its Hindu rulers, equally to the general traveller, the trader, and the man of science. It is however pointed out by the authors of the Manual, that the probably palæozoic slates, sandstones, and limestones of the Lower Himálaya were originally deposited on a highly eroded surface of ancient gneiss, and probably in hollows, and it is suggested by Mr. Blanford, that like the ancient unfossiliferous formations of the peninsula, they may be of freshwater origin, and that the Lower Himálaya may, after all, have formed a portion of the same palæozoic and mesozoic continent, around the shores of which were deposited the fossiliferous shales and limestones of Zanskár, Hundes, and the Western Salt Range, in which case the chain of the Himálayas must have originated along a portion of the ancient coast-line. And we may observe that the junction of the north and south ranges of the lower Indus valley with the north-west and south-east ridges of the Himálaya coincides in a general way with

the region where the palæozoic and mesozoic marine formations appear to the south of the Himálayan axis, the former in the Punjab and Afghanistan, the latter both there and further south, in Cutch, Sind, and Bálúchistán.

The geography of India in the early eocene period may be represented as something like the following:—The whole of the peninsular area was then, as it now is, land, with the exception of some portions of the present coast tract north of Bombay. In like manner the coast of Kaliwár and the greater part of Cutch were submerged, and a deep sea extended up the present Indus valley, and over Bálúchistán, also over the Punjab and parts of Káshmir, sending an arm up the present Ganges valley, which was in part estuarine, and bounded on the north by a tract of land composed of the then uncontorted rocks of the lower Himálaya. To the east of Bengal the present plain of Silhet and a part of the Khasi Hills were probably covered by a shallow sea, and this extended to the southward over Arakan and at least a large portion of Burmah.

It was in this state of things that the first great disturbance took place, which, repeated again and again during middle and later tertiary times, resulted in the present chain of the Himálaya. The river valleys which, after the first great upheaval, were carved out in the then youthful chain, discharged their stream-borne *débris* as now on the Gangetic plain; and the accumulated conglomerates, sands and clays, which formed around the mouths of the valleys, again and again suffered crushing and upheaval during the subsequent compression of the mountain mass, were added to the hills, and in their turn underwent erosion. But the valleys originally marked out have preserved their general course and function; and the Sutlej, the Bias, the Tous, the Jumna, and the Ganges, still flow out from the mountains along essentially the same lines of drainage which their then nameless representatives followed in miocene times. Such, at least, briefly stated, is the history which Mr. Medlicott and his colleagues have evolved during many years' study of these interesting rocks, first made famous through the classic labours of Cantley and Falconer, and by them named "Siwalik."

Not the least interesting chapter of the Manual before us is that in which Mr. Blanford deals with the rich and varied vertebrate fauna of these tertiary rocks. The original collections of Cantley and Falconer have been largely added to in later years by various members of the Survey; and a comparison of the forms obtained from different horizons in the Sub-Himálaya, the Punjab, Sind, Perim Island, and certain river valleys in the Indian peninsula and Burmah, has led to some modification of the opinions originally held of the geological age of the Siwalik rocks and their contained fauna.

As Mr. Medlicott has shown, the Siwalik rocks are an ancient alluvial formation, like the river fans described by Mr. Drew in Kashmir, and like the *Bhábar* deposits still forming along the foot of the Himálaya at the present day. In what may be termed the typical area, between the Sutlej and the Ganges, disturbances of some magnitude which took place after a portion of these deposits had been laid down, necessitate a subdivision of the series into three groups, upper, middle, and lower, the last of which is termed the Náhun group. It is from the two upper groups that (with perhaps some doubtful exceptions) all the fossils of this special region have been obtained, the Náhun group having remained unproductive to repeated search. An elaborate analysis of the homotaxis of the 45 mammalian genera (consisting of 84 species) which compose this fauna shows that the proportion of living to extinct genera is greater than in most miocene deposits. The presence of four extinct genera not known to range above the miocene period is contrasted with the occurrence of sixteen genera, not found elsewhere at a lower horizon than pliocene or post-tertiary; and there is a close approximation between some of the mammals and the living species of the same genera, the most remarkable of all being the connection of the fossil buffalo, *Bos palæindicus*, of the uppermost Siwalik strata, that of the post-pliocene Jumna and Nerbudda beds, and the Common Indian arnee still existing. Of six species of reptiles sufficiently well known to be comparable, three are common forms now inhabiting the same area, and the fresh-water mollusca also all apparently belong to common existing species. Putting the whole palæontological evidence together Mr. Blanford concludes that a balance is in favour of a pliocene age. This conclusion is strengthened by stratigraphical evidence. At the top of the enormous succession of tertiary deposits of Sind, which have a total maximum thickness of some 30,000 feet, occurs a group termed the Manchar group, about 10,000 feet thick, which is of fresh-water origin and represents the Siwaliks of Northern India. The lower beds of this group pass downwards into the Gaj group (1,000 to 1,500 feet thick), which is of marine origin, and contains a characteristic miocene fauna, "more probably upper than lower miocene." The Lower Manchar beds have yielded a considerable number of mammals, and this fauna, although containing several species in common with the Siwaliks, is altogether older in aspect; the majority of the forms hitherto recognised, belonging to the peculiar types of even-toed ungulates allied to *Nierycopotamus* and *Anthracotherium* intermediate in character between pigs and ruminants, and peculiarly characteristic of the miocene epoch. In these lower Manchar beds is also found a form of *Dinotherium*, a type unknown in the Siwaliks. Remarking that "there can be no reasonable doubt that the Manchar beds of Sind, as a whole, correspond with the Siwalik formation of Northern India, the two being portions of a continuous band of tertiary rocks," it is concluded that the fossiliferous lower beds of the Manchar group correspond to the unfossiliferous Náhuns, and the almost unfossiliferous Upper Manchar beds to the ossiferous strata of the Siwaliks. Mr. Blanford then remarks on the probable climatic causes which have preserved in the Indian pliocene an unusually large number of forms elsewhere characteristically miocene; and compares the case with that of the Pikermi beds in Attica, which are of unquestionable pliocene age. He considers that the general cooling of the north temperate zone at the end of the miocene period caused a migration of many of the characteristic mammals into Southern Asia, the Himálayan chain at that epoch not presenting so impassable a barrier as at the present day, and that such was the case seems to be confirmed by the occurrence of rhinoceros and elephant remains in the tertiary deposits of Hundes

at elevations now occupied only by the yak and similar mountain forms.

In reference to the greater richness of the Siwalik fauna, as contrasted with the Indian fauna of the present day, he quotes with approval the suggestion of Mr. Wallace, that a sweeping reduction was brought about by the cold of the glacial period. Of the influence of this cold in India, there are abundant proofs in the great extension of the Himálayan glaciers, for instance, in Sikkim and Kashmir, down to 6,000 feet and 8,000 feet above sea-level; and in the Naya hills of Assam, whose greatest elevation does not exceed 10,000 feet, in the large moraines at 4,500 feet, described by Col. Godwin Austen.

The oldest proofs of man's occupation hitherto met with in India, are a chipped axe or scraper, in the alluvial (post-pliocene) deposits of the Narbada, associated with remains of *Ursus*, *Elephas*, *Rhinoceros*, *Hippopotamus*, *Tetraprotodon*, and *Bos*, all of extinct species; and a flake, apparently of human manufacture, in the Godavari gravels of similar age. Quartzite implements of the palæolithic type are abundant in the laterite gravels of Madras, but these are probably of later date. Axes of neolithic type have as yet been met with only on the surface, most abundantly in the Banda district of the North-West Provinces.

The Manual is illustrated by twenty-one admirably executed lithographed plates of characteristic fossil forms, and a few woodcuts of sketches and sections. Its utility for purposes of reference is rendered all that can be desired by a copious and well-arranged index. We confidently hope that the publication of the work will give an impulse to the advancement of Indian geology by adding largely to the number of non-professional workers, a class which has hitherto been singularly wanting in India, despite the examples of such men as Carter, Forbes, Newbold, Strachey, and Hislop. H. F. B.

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts. No notice is taken of anonymous communications.*

[*The Editor urgently requests correspondents to keep their letters as short as possible. The pressure on his space is so great that it is impossible otherwise to ensure the appearance even of communications containing interesting and novel facts.*]

Prof. Clifford's Mathematical Papers

Having, at the request of Mrs. Clifford and Dr. Spottiswoode, undertaken the editing of the late Prof. Clifford's mathematical papers, I am anxious to secure the co-operation of all mathematicians who are interested in the matter. Prof. Clifford does not appear to have been in the habit of widely distributing copies of his writings, so I have found of many of them a great number of copies, whilst of others I have not come across a single one. I will first state what I have:—

All papers in the *Phil Trans.*, in the *Proceedings of the London Mathematical Society*, in the *Messenger of Mathematics*, in the *Manchester Transactions*, in the *Cambridge Philosophical Society's Journals*, in the South Kensington Handbook, in the *Mathematical Reprint* from the *Educational Times*.

Of the papers in the *Quarterly Journal of Mathematics* I have only §§ 1–11, 17–23, of the *Analytical Metrics*. I should be glad also to have a copy of the *Academy* for August 15, 1873, and information about "Lecture Notes" on Geometry. These last are lithographed and are comprised in twenty-six articles (? all), of which I lack one page, containing § 19–21. I need hardly add I shall be glad to receive any other papers (mathematical) which are not contained in the above-named journals. The Nature article (translation of Riemann) I have. I have Mrs. Clifford's permission to distribute the author's copies of her late husband's papers to mathematicians who may wish to have them. R. Tucker

Pine-Pollen mistaken for Flowers of Sulphur

The following paragraph appeared in the *Times* of June 16:—

"During the past week, after heavy rain, a thin film of sulphur has been observed at Windsor, Slough, and in the neighbourhood generally, to settle upon the surface of rain-water caught in butts and cisterns. The phenomenon at first did not attract much attention, but being observed on different occasions it has given rise to much speculation as to the cause of it, there being no manufactures in the neighbourhood at all likely to have produced it. It has been suggested that a sulphureous vapour may have been wafted to this country by the recent south-east winds, and arrested and deposited in the rain."

The supposed "sulphur rain," a fine yellow dust, was the cause of great excitement among the country people in this neighbourhood. It was first observed on the afternoon of Sunday, June 8, after a remarkably heavy shower, and much disturbed the inhabitants of some of the villages round Eton, who fancied that it smelt "awful like brimstone," of which its yellow colour was somewhat suggestive. In some places it gave rise to such a feeling of fright that the people were afraid to go to bed, thinking that the judgment day was at hand! Two or three days afterwards there was another "sulphur" shower, and I collected a quantity of the dust with my pupils, who were at work with me in my laboratory at the time. One of them, H. Bury, immediately recognised its resemblance to the pollen of *Pinus pinaster*, with which he is familiar from its abundance in the neighbourhood of his home at Bournemouth; and we have none of us any doubt but that this so-called sulphur is the pollen of this tree or of the Scotch fir, *Pinus sylvestris*, both of which are common in Windsor Forest. Two of the Windsor doctors, both practised microscopists, at once came to the same conclusion; but a local chemist and druggist is said (on good authority) to have supported the sulphur theory. This, perhaps, accounts for the rather positive statement by the Windsor correspondent of the *Times* as to the nature of the deposit, and also for the suggestion he refers to respecting its origin, which explains the phenomenon in a manner that is certainly more curious than probable, from a chemical point of view. I hear that the "sulphureous vapour" is supposed to have been "wafted to this country," after escaping from Etna during the recent eruptions, which fortunately occurred at just the right time to give apparent probability to the sulphur theory.

Thinking that such a remarkable phenomenon should not be allowed to pass unnoticed, I sent a short note to the *Times* of the 17th inst., stating the real (pollen) nature of the yellow dust, hoping that this would set the matter at rest and dispel the superstitious fears of the rustics. I was therefore greatly surprised, a few days afterwards, at receiving a letter from an F.R.G.S. residing near Carlow, in Ireland, who had seen my note in the *Times*, but nevertheless spoke of an "extensive fall of sulphur" in his neighbourhood. He was good enough to inclose me a "specimen of its incrustations" on a dead leaf, and said that "till yesterday's heavy rains any quantity of leaves like that I send you might have been gathered, and the edges of the pools of water were heavily incrusted with pure sulphur." He added that he thought I should not find the deposit to be "the produce of *Pinus pinaster*." This, of course, was rather startling, for I naturally supposed that no one would write so confidently who had not satisfied himself by chemical tests and by microscopical examination as to the truth of his statements, especially after hearing of the mistake which had been made in England. A glance at the deposit under the microscope, however, revealed its true nature—pine-pollen again!

I wrote accordingly to my informant, telling him this and sending him some pollen taken directly from the tree, so that he might recognise its similarity to the "pure sulphur" he so kindly sent me. I hope that by this time he has done so.

The above facts are of interest, partly as affording an excellent illustration of the transportation of pollen by the wind, and partly because they show how ready some people are to attribute an almost miraculous origin to anything a trifle out of the com-

mon, which could be readily explained by any one possessing a little elementary knowledge of science.

Intellect in Brutes

IN NATURE, vol. xx. p. 147, Mr. H. D. Barclay writes:—"The fact that a cat or a dog subject their food to examination before eating it, does not, most assuredly, prove the possession of abstract powers of thought in the animal. Mr. Romanes here says:—'The motive of the examination being to ascertain which general idea of quality is appropriate to the particular object examined.'

"Here he attributes to an animal whose nature he does not fully understand, his own process of thought, and this appears to me to be a constant source of error in the investigation of animal psychology. That brutes possess self-consciousness, introspection, imagination, abstract thought, cannot, I think, be proved. The fact that animals possess faculties differing from those of man is an insuperable obstacle to a perfect analysis of their intelligences.

"Name these faculties as you please, call them 'inherited habit,' 'inherited memory,' it is perfectly certain that man does not possess them."

Now, far from it being "perfectly certain" that animals possess mental faculties differing in kind from our own, it seems to me that, if we except the so-called "homing instinct" as a faculty about which as yet we know very little, it is "perfectly certain" that there is no other faculty presented by brutes which is not also presented by man. It is the converse proposition that is more difficult to combat—viz., that man possesses faculties of mind which appear at first sight to differ in kind from anything that is presented by animals. Therefore, while I should deem it almost superfluous to "prove" that man possesses "instincts" or "inherited habits" in common with animals, I have never attempted to "prove" that animals possess "self-consciousness" or "introspection" in common with man. Indeed, if Mr. Barclay will again read my article in NATURE, he will see that I expressly state my belief that these, the highest faculties of mind, may be, as the theory of evolution would lead us to expect they ought to be, confined to the highest product of psychological development.

As regards the illustration to which Mr. Barclay objects, I may observe that I selected it for the express purpose of disarming the criticism which he advances. Had I chosen for an illustration some "general idea of quality" more abstract than that of "good for eating or bad for eating," I could better have understood a critic accusing me of attributing to animals my "own process of thought" in the regions of self-conscious introspection. But seeing that I do not myself require or perform any process of introspective thought in order to reject a rotten egg or to regale myself on good roast beef, I cannot understand why I should not attribute to an animal precisely the same general ideas of "good for eating and bad for eating" that in my own case I know to be the causes of my acting precisely as I see animals act. The truth is that in speaking of general or abstract ideas we are not careful enough to discriminate between those simple ideas of quality which spring from mere sensuous associations, and those more elaborated ideas which spring from the more complex associations that are supplied by "mental reflection." But although it is of importance to remember that there is thus a great distinction between these two orders of abstract ideas, it is of no less importance to remember that both orders belong to the same class—all such ideas having reference to quality as abstracted from particular objects of perception, and the only difference between those of the one order and those of the other consisting in the higher degree of elaboration which is supplied to our abstractions by the power of thinking about our thoughts. On the whole, therefore, I maintain that it *can* be "proved" that animals "possess abstract thought" of the inferior order which I have explained, and the phenomena of dreaming which is presented by several animals would seem sufficient proof that some animals, at least, possess a tolerably well-developed "imagination."

GEORGE J. ROMANES

I HAVE been reading with great interest the letters and discussions lately published in NATURE, on intellect in brutes. However, in none of them have I found any notice of a dog recognising a painted likeness of his master or any member of the family. I have seen, in other publications on this subject, that "this is one of the things a dog has never been known to do." During my residence in Cornwall I had a most intelligent and faithful dog for fifteen years. I had him when a month old. His mother was a beautiful liver-coloured spaniel, rather large; his father a black Newfoundland; my dog took after him in colour and shape.

In 1843 a young and self-taught artist asked me to allow him to paint my likeness in oil colours, and I consented. His studio was in the next town, three miles distant, and as often as required I went over; I, however, did not take my dog with me. It was done in Kit-cat size; and he succeeded so well in the likeness and artistic work, that when exhibited at the annual meeting of the Polytechnic Society at Falmouth, a medal was awarded to it, and, as well, it was "highly commended." Not only this, it brought him into notice and gained him lots of employment. The artist was so grateful for my attention that he presented me with the painting, and I still have it. When it was brought to my house, my old dog was present with the family at the "unveiling;" nothing was said to him nor invitation given him to notice it. We saw that his gaze was steadily fixed on it, and he soon became excited, and whined, and tried to lick and scratch it, and was so much taken up with it that we—although so well knowing his intelligence—were all quite surprised; in fact, could scarcely believe that he should know it was my likeness. We, however, had sufficient proof after it was hung up in our parlour; the room was rather low, and under the picture stood a chair; the door was left open without any thought about the dog; he, however, soon found it out, when a low whining and scratching was heard by the family, and on search being made, he was in the chair trying to get at the picture. After this I put it up higher, so as to prevent it being injured by him. This did not prevent him from paying attention to it, for whenever I was away from home, whether for a short or long time—sometimes for several days—he spent most of his time gazing on it, and as it appeared to give him comfort the door was always left open for him. When I was long away he made a low whining, as if to draw attention to it. This lasted for years, in fact as long as he lived, and was able to see it. I have never kept a dog since he died, I dare not—his loss so much affected me. I might tell of many of his wonderful actions; he could do most of such things as are related of other dogs. I am now only anxious to notice this recognition of my likeness, from never having heard of another such fact being recorded of any other dog.

Edinburgh CHAS W. PEACH

A CASE somewhat similar to that mentioned by Dr. Frost, of a cat scattering crumbs, occurred here within my own knowledge.

During the recent severe winter a friend was in the habit of throwing crumbs for birds outside his bedroom window. The family have a fine black cat, which, seeing that the crumbs brought birds, would occasionally hide herself behind some shrubs, and when the birds came for their breakfast, would pounce out upon them with varying success. The crumbs had been laid out as usual, one afternoon, but left untouched, and during the night a slight fall of snow occurred. On looking out next morning my friend observed Puss busily engaged scratching away the snow. Curious to learn what she sought, he waited, and saw her take the crumbs up from the cleared space and lay them one after another on the snow. After doing this she retired behind the shrubs to wait further developments. This was repeated on two other occasions, until finally they were obliged to give up putting out crumbs, as Puss showed herself such a fatal enemy to the birds.

Aquarium Notes

Marine Copepoda—The lump-sucker.—In the salt water tanks of the Edinburgh Aquarium at the present date may be seen an immense number of white specks flitting rapidly through the water, after the fashion of the familiar *Cyclops* and its neighbours in fresh streams. On subjecting these "tenants at will" of the tanks to microscopic scrutiny, they are seen to belong to the Entomostracous division of the crustacea, and may in all probability be classified in the cyclops-family, as near kith and kin of the well-known "fresh-water flea." The cephalothorax

is well-defined, the body being flattened, whilst the posterior edges of the cephalothorax are prominent and somewhat hooked. The feet number five pairs, and are setose. No external ovisacs exist, and the antennæ are of simple conformation. Under the microscope the intestinal canal, filled with brownish matter, is seen to pulsate in rhythmical fashion. The abdomen is apparently composed of some four joints, and is terminated by two long caudal bristles. The eye is single, median, and red-coloured. In the absence of more definite characters, I should feel inclined to allocate the form near the genus *Alteutha*, of Baird, from the hooked character of the cephalo-thoracic edges. It differs from *Alteutha*, however, in the absence of the characteristic hooked edges of the fourth somite of the abdomen. The sudden appearance of myriads of these creatures in the tanks may probably be attributed to the recent favourable temperature; the eggs of the adults having lain dormant, as do the cyclops themselves, through the winter.

In the tanks are shown at present several large specimens of the lump-sucker (*Cyclopterus lumpus*). These fishes, as is well known, adhere by means of their sucker (formed by the modified ventral fins) to fixed objects. Watching a lump-sucker firmly attached to the glass of the tank, the idea occurred to me that the sucker may have been developed by natural selection, as a useful adjunct to the breathing-movements of the fish. When fixed, the fish appears to be perfectly at ease, and to breathe more fully and strongly than when swimming. The movements of the opercula, or gill-covers, when the fish was attached, were specially strong, as compared with their motion in the act of swimming. In a large-headed and heavy-bodied fish like *Cyclopterus*, any aid given to the respiratory movements would be a clear gain to the animal; and from a habit simply of resting on an object so as to afford leverage and play to the gills, the comparatively useless ventral fins may have become specially modified as a disc of attachment. The development of the sucking-disc and enlargement of the branchial cavity would thus proceed *pari passu*, and by natural selection the present exaggerated features of both organs would be attained. It would be interesting to know whether the history of cyclopterous development might or might not confirm these suggestions. The lump-suckers have spawned in our tanks, but unfortunately there has been no attempt on the part of the males to fertilise the ova.

Edinburgh, June 14 ANDREW WILSON

Snails *v.* Glow-worms

SOME years ago I brought three glow-worms from Wales to London, and at night I put them on the grass, when all showed their lights; but on looking for them a short time after, one had nearly disappeared, and on searching for it my hand came against something cold, and on taking it to the light I found it was a snail—one of those which just now are very common—about $1\frac{1}{2}$ inches long by $\frac{1}{4}$ inch diameter, and of a sandy colour. The brute had swallowed the glow-worm, and I could see the light shining inside!

As there are no glow-worms in this part of the country, I wish some one who has the chance would try the experiment again, by placing a glow-worm and a snail near to each other, and report the result. R. S. NEWALL

Ferndene, June 22

Oxygenated Rain

THIS morning I have read Mr. Solly's note on this subject. Yesterday, June 21, we had a thunderstorm, and while looking at the lightning I noticed that the rain falling on the window-glass had what I first thought were small particles of hail in the drops; but on magnifying it I found that the opacity was caused by a number of very small air-bubbles, which soon disappeared.

These drops fell during the shower, and only for an interval which I think did not exceed ten seconds, for I had only time to take the magnifier out of my pocket and observe a few drops, after which no more fell which contained air-bubbles.

One flash of lightning left a track which lasted about five seconds, and gradually faded. This was also observed by one of my family who was observing at a distance of 1,000 feet from where I was. R. S. N.

Butterfly Swarms

THE swarms of butterflies alluded to in NATURE, vol. xx. p. 183, have been observed in various localities of Switzerland—Lausanne, Morges, the foot of the Jura, &c. The passage lasted a long time, from one to four hours, on June 9; the species was *Vanessa cardui*. By comparing the hours and dates of the appearance in the various localities, I am convinced that it is simply due to the extraordinary local fecundity of this species, and not to a migration of butterflies from Africa or the shores of the Mediterranean, as various French and Swiss journals have supposed. F. A. FOREL

Morges, Switzerland, June 23

Meteor

I SAW a bright meteor at Bath last night. It flashed into sight at a spot some 10° to the south of Arcturus at 10.38 P.M. The duration of its visibility was between two and three seconds, the direction of its path very nearly north-east to south-west, its brilliancy quite that of one of the so-called "fire-balls" in pyrotechnic displays. It travelled through about 25° of arc, leaving a very faint trail, which however disappeared almost immediately. What struck me as particularly remarkable about the meteor was the decided bluish-green colour of its light.

June 19 C. ARMBRUSTER

JOSEPH WILSON LOWRY, F.R.G.S.

DEATH has just erased another well-known name from the roll of workers on the Geological Survey of Great Britain, that of J. W. Lowry, the eminent engraver whose maps, sections, and plates of fossils form so interesting a part of the records of this important branch of the scientific public service.

Joseph Wilson Lowry was the only son of Wilson Lowry, F.R.S., and Rebecca Lowry, well known as a mineralogist some seventy years ago; he was born October 7, 1803. His father was the leading architectural and mechanical engraver of his time, and he trained up his son to follow his own pursuits. From his early youth his father's house was the resort of men of high intellectual culture, and his mother's pursuits leading her also to associate with the scientific men of the day, what wonder that young Lowry early imbibed his parent's tastes and became an ardent lover of all natural history studies and pursuits, an accomplished draughtsman, and a well-informed scientific man.

His first practical effort was directed to the construction of a model in plaster of the Isle of Wight, geologically coloured, and divided transversely so as to give a section (also geologically coloured) through the centre of the island.

His pursuit of natural science led him early in life to become acquainted with John Phillips, at that time keeper of the Yorkshire Philosophical Society's Museum in York, and later on, when Assistant-General Secretary of the British Association for the Advancement of Science, or when associated with De la Beche on the Geological Survey, or when Professor of Geology in Oxford, until his death, Prof. Phillips remained the sincerely attached friend of J. W. Lowry.

Lowry's first important work as an engraver was the execution of the plates for the "Encyclopædia Metropolitana." He also executed for Sir John Rennie a series of plates of London Bridge. For many years Mr. Lowry prepared all the engravings for Scott Russell illustrative of wave-lines and the contours of ships. Mr. Lowry designed and executed numerous maps and charts for the Society for Promoting Christian Knowledge, the illustrations for Weale's Scientific Series, the atlas of maps published by the *Dispatch* newspaper, the first really cheap and good atlas ever produced.

The plates illustrating Phillips's "Geology of Yorkshire," and many other scientific works, were engraved by Mr. Lowry. We are also indebted to him for the excellent series of Natural History Charts of British Fossils, stratigraphically arranged, British Tertiary Fossils, Recent and Fossil Crustacea, by Dr. H. Woodward and J. W. Salter, &c. (Stanford's).

Hundreds of plates of fossils, exquisitely engraved, and maps and sections, too numerous to recount, published for the Geological Survey of Great Britain, amply testify to Mr. Lowry's rare ability as a scientific engraver. Even the familiar card-maps of each town visited year after year by the British Association were invented and produced by Mr. Lowry's skill and ingenuity.

But the days of engraving seem drawing to a close, at least so far as *printing* from engraved plates is concerned; but the beautiful plates prepared by Mr. Lowry cannot well be surpassed by modern lithography, save in cheapness.

Much as Mr. Lowry's work was valued by scientific men, his amiability of disposition and his modesty won for him even higher esteem among his friends. Many who knew him personally will recall his readiness on all occasions, even at great personal sacrifices, to help those who needed his assistance. His freshness of heart and kindness to young people were marked features in his character. He died on June 15. H. W.

DAVID MOORE, PH.D.

THE death of the Director of the Royal Botanical Gardens at Glasnevin, near Dublin, on June 9 last, has caused a very wide-spread sorrow among the botanists and horticulturists of Europe. Although Dr. Moore had attained the age of seventy-two, yet his physical strength was but little abated, and his mental powers were as strong as they were mature. A peculiarly severe attack of acute cystitis of scarcely four days' duration deprived us of a truly excellent and amiable man.

A native of Dundee, his father, attracted by the fame of Dr. MacKay, the Director of the Botanical Gardens belonging to the University of Dublin, and well known as the author of the "Flora Hibernica," sent David Moore to Dublin to be MacKay's apprentice. The apprentice soon learnt all the master had to teach, and was not long in qualifying himself to form one of the government staff, to whom, under the superintendence of the late General Portlock, was intrusted the Ordnance Survey of Ireland. This was in 1834; the Survey began in the County of Londonderry. In 1837 the first volume of its *Memoirs* was published, to which Moore contributed an essay on the flora of the region surveyed. Shortly after this he was elected by the then Council of the Royal Dublin Society to the charge of their Botanical Gardens at Glasnevin. These gardens are situated within a couple of miles of Dublin, and present a pleasing alternation of flat and gently rising ground, which then slopes to the borders of the little trout stream called the Tolka. They are associated with the memories of Tickell and Swift, and one walk amid old yew trees is still pointed out as the one much frequented by the Dean when inclined to moody meditation. To enumerate the changes brought about in these Gardens during the forty years' work of Moore, would be to write his and their history. It might almost be said that he found them a mixture of pleasure-ground and herb-garden; he has left them with all their native loveliness shown off to its very best, and containing for their size one of the best stocked collections in Europe. As the stranger walked there he was told of the literary men who sought for rest and quietness amid their shade; to the list of these sacred memories will now be added the name of a scientific man, whose daily labour for just forty years has resulted in making them known throughout the world. Amidst the practical labours of Moore's life science was not forgotten. He ably assisted MacKay in compiling his list of Irish plants. But he also devoted a great deal of attention to compiling a history of the mosses, liverworts, and algæ of his adopted country, and as the result of his maturer labours in this direction, he published in 1872 an account of the mosses of Ireland, and four years later an account of the Irish Hepaticæ. He, conjointly with A. G. Moore, F.L.S., published an account of the geographical distribution of plants in Ireland, under the title of "Cybele Hibernica." This is scarcely the place to record the numerous plants introduced by him to our gardens and stores, or to refer to the many interesting new hybrid forms brought into existence through his skill. For such scientific labours he was rewarded by being given the Ph.D. of Leipzig University, and with what we know he regarded as nearly as great an honour, in having the twenty-ninth volume of the third series of the *Kew Journal of Botany* dedicated to him by Sir Joseph Hooker, as "to one who, maintaining a very rich and beautiful botanic garden at a high standard of excellence, has advanced botanical science by many original observations and experiments."

Long will the memory of David Moore dwell in the minds of his many friends as that of one true and faithful, genial and generous.

THE RECENT ERUPTION OF ETNA

PROF. SILVESTRI has, with most commendable despatch, just issued his report to the Italian Government on the recent eruption of Etna. It takes the form of a quarto pamphlet of nineteen pages, entitled *Sulla doppia eruzione dell' Etna scoppiata il* 26 *Maggio*, 1879, and it is accompanied by a capital map, showing the exact extent and dimensions of the lava-streams. A reference to the map accompanying the previous article (p. 158) may help the reader to understand more clearly what follows.

At the end of our former article on the subject, we mentioned certain anomalies in the accounts of the eruption already transmitted by telegram from Rome, and at the same time asserted that we must wait for the Government Report before they could be explained. It is satisfactory to find that Prof. Silvestri has completely removed these anomalies, and has given a description of the eruption, which is so connected, reasonable, and precise, that it leaves nothing to be desired.

Silvestri considers that preparations for this eruption have been continued since 1874, and that this is the fulfilment of the abortive attempt which was then made. On August 29, 1874, a rift opened on the north-east side of the mountain, between the great crater and Mojo, and thirty-five small eruptive mouths were formed along its course, together with one larger crateriform monticule, which discharged lava. But after seven hours of activity, the dynamic forces suddenly decreased in intensity, and in two days' time nothing remained of the eruption save a few secondary manifestations. For a fortnight afterwards, however, earthquakes occurred on the north side of the mountain, and the great rift remained open. Silvestri predicted that when the next eruption came, this rift would prove the point of least resistance, and that the new lava would flow from it, or from craters raised along its course. This prediction has been completely verified.

The fissure of 1874 has extended itself—on the north-north-east towards Mojo, on the south-south-west towards Adernò. It is 10 kilometres (6·2 miles) in length, and passes through the great crater of Etna. On May 26, the south-western extremity discharged lava in the direction of Adernò while simultaneously the north-eastern extremity discharged lava in the direction of Mojo, thus presenting the curious anomaly of twin eruptions on opposite sides of the mountain. The craters on the south side of the mountain were situated near the base of Monte Frumento 2,650 metres (8,743 feet) above the sea. There were eight eruptive mouths, from 4 to 15 metres in diameter; seven of these were open, while over the eighth was raised a monticule. The lava did not flow directly towards Adernò, 13 kilometres distant, but towards a series of monticules formed during a previous eruption, and known as *Monti Grotta degli Archi*. It accumulated against the

first of these mounds, and then divided into two branches' one of which commenced to flow towards Adernò, and the other towards Biancavilla, but the supply died out at the source, and the new streams solidified at a height of 2,000 metres, having flowed for a mile and a quarter as a stream 400 metres in breadth. This stream did but little damage; it did not penetrate into the cultivated region, and but in short distance into the woody region. It came into contact, however, with a bed of snow, part of which it converted into clouds of steam, while another portion was liquefied and rushed down the sides of the mountain in a foaming torrent, carrying with it a good deal of *débris*.

The outflow of lava ceased on the south side of the mountain, because the lava found a vent at a lower level on the north side. As the one decreased in activity the other increased. On May 28th Silvestri visited the scene of the northern eruption. A great column of smoke appeared about 20° east of north, while a shower of sand descended, producing the "sad leaden light" (*la luce triste plumbea*) observable during an eclipse. More than two pounds of this sand were collected in ten minutes in an inverted umbrella, and the north flanks of the mountain were soon covered with it. Silvestri ascended from Randazzo towards the new craters, and when at a height of about 2,000 metres and near Monte Nero he heard loud subterranean detonations, and perceived severe oscillations of the soil. Soon afterwards he came upon the great rift, together with several smaller ones, converging towards the principal crater. In the immediate neighbourhood of Monte Nero and Timpa Rossa three new craters were seen, from one of which dense clouds of white smoke issued, while the others emitted lava and showers of ashes and incandescent stones. Frequent flashes of lightning issued from the smoke. The stream of lava near its source emitted a very bright light which, when viewed by a direct vision spectroscope, gave the lines of hydrogen, calcium, sodium, and potassium. The lava flowed downwards at a rapid rate: the wood of Collebasso was destroyed, and by the evening of May 29 it had flowed $6\frac{1}{4}$ miles, destroying the bridge of Passo Pisciaro and crossing the postal road between Randazzo and Linguaglossa. On Sunday the 31st the stream was rapidly approaching Mojo; the inhabitants became frightened, and brought out the figure of their patron Saint Antony, which was carried in procession to the edge of the stream, while the people fell on their knees and besought the Deity to save them from the impending danger. After the evening of June 1 the force of the eruption began somewhat to abate, and by the 6th inst. it was practically at an end. The lava stream ran nearly 7 miles from its source, and ultimately stopped 500 yards from the river Alcantara, and about half a mile from the village of Mojo. At its termination it is 23 feet in breadth and nearly 32 feet in height. The lava stream entered the bed of the Pisciaro torrent with a velocity of from 4 to 5 metres a minute, which was reduced to 2 metres a minute in the lower valley of less inclination. In 76 hours the lava flowed more than six miles from its source.

Indications of a disturbed volcanic condition were manifest last October, when powerful shocks of earthquake were felt in the territory of Mineo, Palagonia, Vizzini, Scordia, Militello, and Caltagirone. Mineo was the centre of disturbance, and here the shocks continued at intervals during the month of October. Loud subterranean noises were also heard at intervals. Two months later an eruption of mud and gas took place near Paternò, on the southern flanks of Etna. The mud was hot, salt, and petroleum-bearing (*fango salato termale petroleifero*), and its ejectment continued for several months. Towards the end of December last the whole eastern sea-board was visited by a strong shock of earthquake; and soon afterwards a great increase of smoke from the central crater of Etna showed that the dynamic activity of the mountain was unusually near the surface.

Even now we cannot regard the eruption as at an end Ten days after the cessation of the flow of lava telegrams from Rome (dated June 17) announced that the neighbourhood of Santa Venere and Guardia had been visited by repeated shocks of earthquake. A telegram on the following day announced that "an earthquake of great violence" had occurred near Aci Reale, destroying five villages. There is evidently a great deal of volcanic energy still pent up not far from the surface, and we must fear that before long a further outburst will relieve the imprisoned Titanic forces.

G. F. RODWELL

THE ELECTRIC DISCHARGE WITH THE CHLORIDE OF SILVER BATTERY[1]

II.

THE HISTORY OF A TUBE

No. 129, *Hydrogen*

WE now give an account of the very great variety of phenomena presented by the same tube charged with hydrogen, No. 129 (see Plate), under different conditions of exhaustion when used in connection with batteries of various potentials, and traversed by currents of different strengths.

This tube is 32 inches long and 1·6 inch in diameter, the terminals are a straight wire and a ring, about 1 inch in diameter, both of aluminium; it is furnished with a glass stop-cock at each end, as represented in Fig. 3. The glass stop-cocks are connected with the mercurial pumps (Alvergniat and Sprengel) and with the gas generator respectively, as shown in Fig. 5.

Tube 129, 5*th Charge of Hydrogen.*—A glow at both terminals was first seen when the pressure was 17·2 mm., 22,632 M,[2] with 8,040 cells, and great heat developed in the dark discharge near the middle of the tube. The spectroscope showed faintly the C and F lines.

Pressure 16·5 mm., 21,710 M, 8,040 cells. One luminosity like that on the right hand of Fig. 10, sho out from the positive and approached to within 6 inches of the negative, then receded back and disappeared.

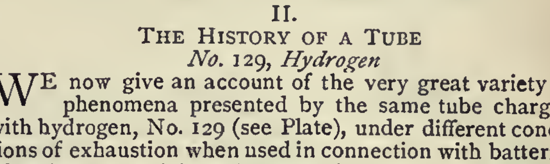

FIG. 10.

Pressure 15·8 mm., 20,789 M, 8,040 cells. 3 luminosities, very steady, which moved slowly and steadily towards the negative. The tube hottest in dark part where there was probably a non-luminous entity.

Pressure 14 mm., 18,421 M, with 6,840 cells, the current was unsteady, but it was perfectly steady with 8,040, and 6 arrow-headed luminosities like that on the left of Fig. 11, were produced and soon disappeared.

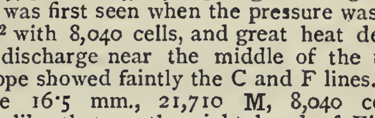

FIG. 11.

Pressure 10·3 mm., 13,552 M, with 8,040 cells. 8 luminosities something like 1, Fig. 12.

Pressure 9·4 mm., 12,368 M, with 8,040 cells. 12 luminosities like those, Fig. 7 in the Plate. The C and F lines seen in the glow around the negative.

Pressure 7·7 mm., 10,132 M, with 8,040 cells. 10 luminosities like Fig. 6 in the Plate; these ran together and disappeared and reappeared in a few seconds.

[1] Continued from p. 178.

[2] M = millionths of an atmosphere

Pressure 6·6 mm., 8,684 M, with 8,040 cells. 12 luminosities very similar to those shown at Fig. 5 in the Plate, the last adhering to the positive. The C line not visible in a nebulosity with the spectroscope, but that and the F line were both to be seen in the glow around the negative.

Pressure 5·9 mm., 7,763 M, 8,040 cells, C. 0·02056 W.[1] 13 luminosities like those Fig. 6 in the Plate. With 100,000 ohms, C. 0·01390 W, there were 10 luminosities not so wide as those when there was no resistance.

Pressure 6·1 mm., 8,026 M, 8,040 cells, C. 0·01910 W. At first 13 luminosities a little unsteady, then $11\frac{1}{2}$ per-

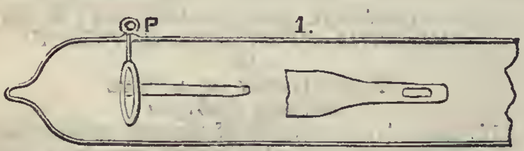

Fig. 12.

fectly steady, like Fig. 6 in the Plate. F and C visible in the glow around negative. F was not visible in a luminosity.

Pressure 4·4 mm., 5,789 M, 8,040 cells. 12 luminosities as depicted in Fig. 6 in the Plate, which is copied from a photograph[2] obtained in 4 seconds.

Pressure 4·0 mm., 5,263 M, 8,040 cells. 15 luminosities as shown in Fig. 7 in the Plate, from a photograph taken in 4 seconds.

Pressure 3·6 mm., 4,737 M, 8,040 cells, 30,000 ohms resistance. 15 luminosities almost touching, like Fig. 7 in the Plate.

Pressure 3 mm., 3,947 M, 4,800 cells, C. 0·0362 W, the resistance of the tube being 88,600 ohms. There were 24 steady blue strata and a space of about 6 inches con-

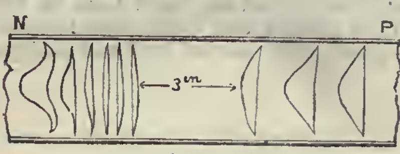

Fig. 13.

fused towards the positive; with 200,000 ohms resistance in the circuit the strata became pink, the current being 0·01469 W.

Pressure 1 mm., 1,316 M, 3,600 cells, C. 0·03896 W, the resistance of the tube being 59,170 ohms. The tube was filled to within one inch of the negative with strata all blue, but they turned pink and tongue-shaped when 200,000 ohms resistance was introduced, which reduced the observed current to 0·00782 W. The C and F lines visible in the luminosities. When 7,590,000 ohms resistance was introduced, a very close and somewhat agitated pink stratification was produced, like the left of Fig. 13.

Some gas let in, pressure 3 mm., 3,947 M, 3,600 cells gave a current of 0·04901 W; the resistance of the tube was ascertained by substituting 47,000 ohms wire resistance, which produced the same deflection. The strata were blue, like those of 55 and 56, Fig. 14. For about 10 inches from the negative they took up an axial backwards and forwards steady rotation of about a quarter turn.

With 174,000 ohms resistance, making with the battery and tube a total of 261,000, the current measured was 0·00879 W. The strata turned pink and assumed the tongue-form, Fig. 15; with 783,000 ohms in circuit very close strata. In the rotating mirror a flow *towards the positive* was observed until a break occurred in the stratification; the flow was then irregular and backwards and forwards.

Pressure 1·7 mm., 2,237 M. The current of 2,400 cells passed; with 3,600 cells the current was 0·03858 W, producing perfectly steady strata, of which a photograph was obtained in four seconds; a facsimile of it is given, Fig. 8 in the Plate. The strata were blue, but on introducing 500,000 resistance the current was reduced to 0·00175 W, and the strata turned pink and assumed the form Fig. 9 in the Plate, which is a facsimile of a photograph obtained in 19 seconds.

Pressure 0·8 mm., 1,052 M, 3,600 cells (C.) 0·19940 W. A spiral series of tongues depicted in Fig. 10 in the Plate, from a photograph which, however, could scarcely be exposed long enough in consequence of the screw-like motion of the tongues. This motion appeared to be from positive to negative.[1] On introducing 900,000 ohms resistance, (C.) 0·003414 W, the tongues grouped themselves in pairs, of which there were 40, and changed from blue to pink. Examined with the spectroscope, the line C had disappeared. The tube was connected with the condenser of 42·8 microfarads and 3,240 cells, a resistance of 200,000 ohms being in circuit (C.) 0·007461 W. At the full potential the same spiral series of blue tongues, quite steady, was produced, and these made a complete rotation in 30 seconds. On breaking connection between the battery and condenser, the strata gradually changed to pink as the charge of the condenser ran down through the tube.

Tube 129, 6th Charge of Hydrogen.—The tube, at 0·9 mm., 1,184 M, was partially charged with hydrogen by letting in 4 small calibrated charges, which increased the pressure each time 1·4 mm., pressure 6·5 mm., 8,684 M, the resistance of the tube was found to be 170,000 ohms, and the total resistance of the whole, 8,040 cells, 130,000 ohms, or an average of 16·6 per cell. With 6,960 cells the current, through the tube alone, was 0·02456 W, and there were produced 9 luminous entities as shown in Fig. 5 in the Plate, taken from a photograph obtained in $1\frac{1}{2}$ second.

The gas in the tube at the same pressure, namely,

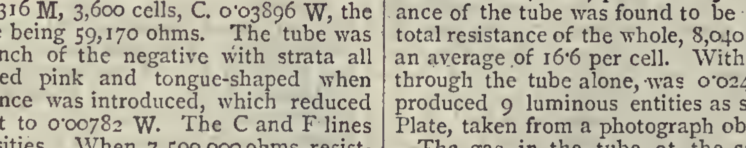

Fig. 14.

6·5 mm., 8,040 cells, C. 0·02634 W. There were 7 entities as depicted in Fig. 4 in the Plate, copied from a photograph obtained in one second.

Pressure 6·5 mm., on the introduction of 300,000 ohms resistance with 8,040 cells, C. 0·0138 W, making a total resistance, inclusive of the tube and the battery, of 600,000 ohms, two luminosities were produced as seen in Fig. 2 in the Plate, taken from a photograph obtained in 2 seconds, which, however, had to be corrected from a drawing, as there was a slight movement in the luminosities.

Pressure 3·6 mm., 4,737 M, 4,800 cells. Strata resembling Fig. 16, but near the negative the strata were

[1] C denotes currents; W webers.

[2] Varley, C. F. (*Proc.* Roy. Soc., xix., 1871, pp. 238–239) succeeded in photographing by an exposure of thirty minutes an *arch discharge* in a vacuum tube, so faint that in a perfectly dark room he was "sometimes unaware whether the current was passing or not."

[1] De la Rive (Genève *Mém.* Soc. Phys. xvii., 1863, p. 72) describing the appearance of a nitrogen tube, says: "Ces stries semblent former une hélice animée d'un mouvement de rotation autour de son axe."

indistinct. In the rotating mirror the distinct strata were steady, but in the indistinct portion there was indicated a rapid flow *towards the positive*. The lines C, F, and G seen in the glow around negative terminal, but C and G were not seen in the strata.

Pressure 1·2 mm., 1,579 M, 2,400 cells, C. 0·03251 W. 11 narrow strata, umbrella-shaped, about $\frac{3}{8}$ of inch wide, followed by two about $1\frac{1}{4}$ inch wide, then a confused discharge, in which the rotating mirror showed a rapid flow *towards the positive*. C, F, and G lines visible in

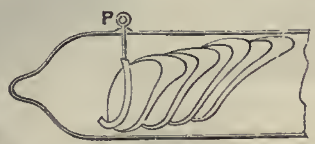

FIG. 15.

the negative glow; G and C disappeared in the strata, and F was very faint.

Tube 139, *Hydrogen*.—Pressure 6·319 mm., 8,314 M, 8,040 cells. Three arrow-headed luminosities as depicted in Fig. 3 in the Plate, copied from a photograph and a drawing made at the time. The photograph was obtained in 2 seconds.

Pressure 9·502 mm., 12,526 M, 6,960 cells. One luminosity of which a photograph was obtained in 10 seconds but has not been copied. Another photograph obtained

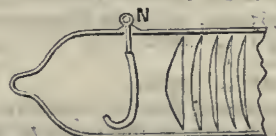

FIG. 16.

in 1 minute is shown in Fig. 1 in the Plate, it will be observed that it has a spear-head continuation towards the negative.

Pressure 0·051 mm., 67 M, the current of 3,600 cells passed intermittently; 4,806 cells, C. 0·00191 W, produced a continuous illumination from the positive to within 3 inches of the negative, the discharge at the negative licking the inside of the tube.

Pressure 0·01 mm., 13 M, the current of 4,800 rod cells just passed: with 6,960 cells the current produced no appreciable deflection of our galvanometer which would indicate 0·00024 W. The strata thickened and became much wider. The discharge at the negative licked the side of the tube and was very sensitive to the approach of the finger.

By standing 16 hours the pressure had somewhat increased without leakage having occurred, and was 0·037 mm., 49 M, 6,960 cells, current less than 0·00024 W; the discharge was milky white and quite different from anything before seen by us with a hydrogen residual charge. The strata had become still broader, the negative discharge hugging the tube and being very sensitive to the finger. The C and F lines could not be seen with the spectroscope, but there was a double green line near *b*.

A charge of hydrogen was let in, the charge being 0·001725 of the capacity of the tube and pump, and increased the pressure to 1·311 mm., 1,725 M. 3,600 rod cells produced a stratification composed of umbrella-shaped strata, united in the middle of the tube by a luminosity one-third the length of the tube. The double green line near *b* had disappeared, and the C, F, and G lines were visible in the spectroscope.

Another calibrated charge of hydrogen was let in and raised the pressure to 2·622 mm., 3,550 M; the current of 3,600 cells just passed: with 4,800 cells a phase was produced resembling tube 129, Fig. 7 in the Plate.

Another most interesting tube was a favourite of our friend the late Mr. Gassiot, and was presented by him, with many others, to Mr. Spottiswoode. It retains, in a remarkable degree, the record of old stratification by bands of dark deposit with clear spaces between them. It was a matter of interest to ascertain whether the lines of deposit coincided with the position of the spaces or with that of the strata. This tube is composed of a cylinder 13 inches long, and $1\frac{3}{16}$ inch in diameter, having at one end a bulb 2 inches in diameter, from which project at right angles to the main tube two short lengths of tube $1\frac{1}{3}$ inch in diameter, the whole resembling in form the letter T. At the end of the tube opposite the bulb is a straight brass wire $\frac{1}{16}$ inch in diameter screwed on to a wire of platinum, and in the head of the T a brass wire, $4\frac{3}{4}$ inches long, reaching axially right across. The bulb and short tubes attached to it are completely coated with a dense black metallic deposit, and for a space of 5 inches from the bulb, the main tube is stained with eight dark bands. 2,400 cells gave a current 0·02289 W, the straight wire being positive, and the cross wire in the bulb

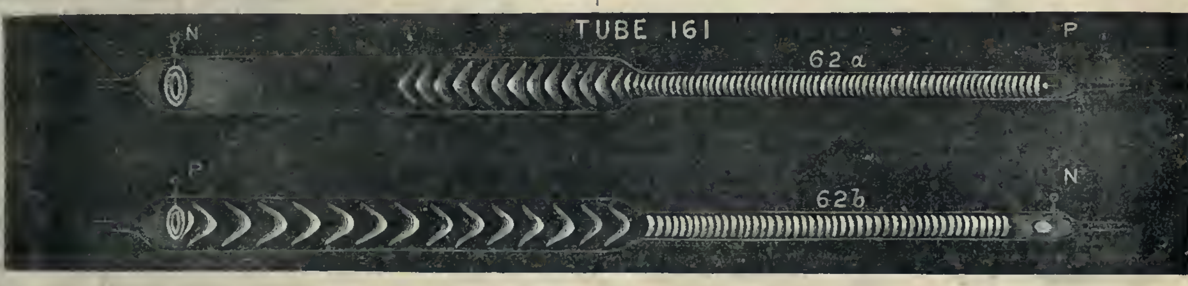

FIG. 17.

negative; there were produced beautiful double strata intensely blue, completely filling the tube. Strips of paper were fastened over these strata in the region of the stains; these were found to occupy the *unstained spaces*; the stains therefore marked the *intervals*, or cooler parts, between former strata.

Tube 161, *Hydrogen*.—The difference of the strata in tubes of different diameter at the same pressure and with the same current is very clearly brought out in tube 161, composed of two portions, one being 18 inches long and 1·65 inch internal diameter, the other 17·5 inches long, and 0·975 inch diameter, the ratio of the sectional areas being 2·864 to 1. The terminal in the small tube is a point, in the large one a ring.

With 4,800 cells, the point (small tube) positive C. 0·02825 W, there were produced in the small tube 62 disk-shaped strata, and in the large tube twelve cup-shaped strata occupying half of the length of the large tube; beyond these the discharge was dark. With the point negative, C. 0·02451, there were produced in the small tube 54 disks, and in the large tube thirteen cup-shaped, completely filling it. The number of strata does not, therefore, appear to be in the inverse ratio of the areas. The strata in the small tube were blue, but

at times, with a large current, carmine, as in the capillary part of a spectrum-analysis hydrogen-tube, the strata in the large tube being much fainter and pink. The appearance when the point was positive is shown in the diagram, Fig. 17, 62*a*, and when negative in 62*b*, copied from photographs obtained, the former in 15 seconds, the latter in 10 seconds. Another example is shown in Fig. 12 in the Plate.

Tube 160, *Hydrogen.*—This tube was constructed with the object of sending the analogue of a smoke ring through a tube in which a steady stratification had been procured and sustained; Fig. 18 shows the arrangement.

The tube is 40 inches long and 1·875 inch in diameter, and has a stop cock at each end; near one of the ends is a small tube, 0·75 inch in diameter, sealed to the main

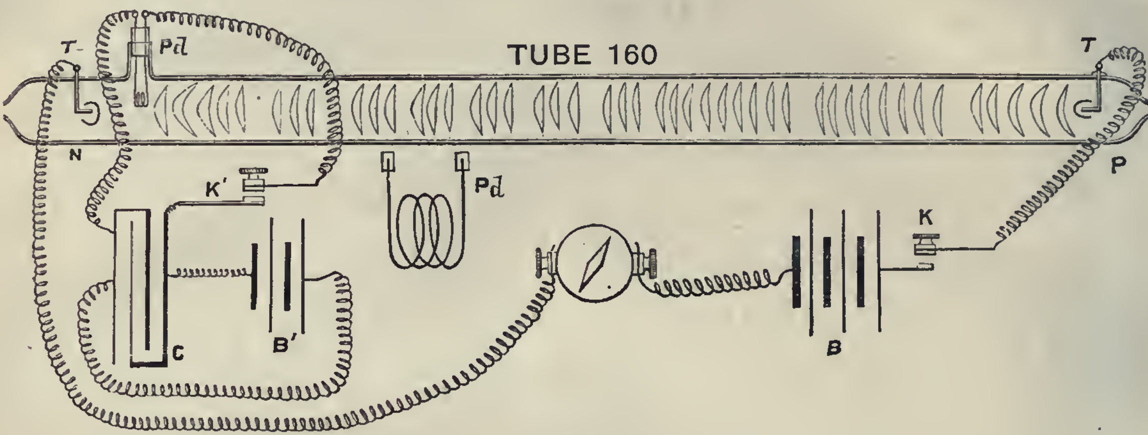

FIG. 18.

tube at right angles, and fitted with a glass stopper, in which two stout platinum wires, 0·043 inch diameter, are melted; there is soldered, with gold, to the two platinum wires a spiral of palladium made of wire 12 inches long and 0·0125 inch diameter, P*d*, in the diagram. The palladium coil was charged to saturation with hydrogen, by immersing it in dilute sulphuric acid and making it the negative pole of a bichromate battery of six elements; after it had been washed in distilled water it was dried and inserted in the tube. The two stout wires of platinum, to which the palladium coil is attached, are connected to a condenser of 10·9 m.f., charged with 3,240 cells. One of the wires leads to the key K′, so that no current can pass from the condenser until this key is pressed down; when this is done the charge passes, and by suddenly gniting the wire drives off the hydrogen.

4,800 cells without external resistance:—

Pressure 0·9965 mm., before the discharge of the condenser,
,, 1·0381 ,, after ,, ,,

Difference 0·0416 ,, 55 M,

strata were produced from the positive up to the palladium coil which was on the negative side. On liberating hydrogen by the discharge of the condenser these were driven back 14 inches towards the positive, and subsequently only a confused discharge was produced.

When the terminal near the coil was positive the same phenomena were not produced on the discharge of the condenser.

In order to test whether it would be possible to render evident pulsations in the current when perfectly steady strata are produced in tubes containing residual gases, we arranged the detector apparatus as shown in Fig. 19.

A Z is the battery; A being connected through the fluid resistances F R, F R′ (which can be plugged out of circuit by means of P and P′), the megohm wire resistance, and the primary of Apps' induction-coil No. 819, to the terminal T′ of the tube; the terminal A is also connected direct to one plate of the condenser C. Z is connected through the key K to the fluid resistance F R″ (which can be plugged out by pressing down the key K′), thence to the other plate of the condenser, and through the safety-wire to the other terminal T of the tube. The secondary wire of coil 819 is connected to a delicate Thomson galvanometer T.

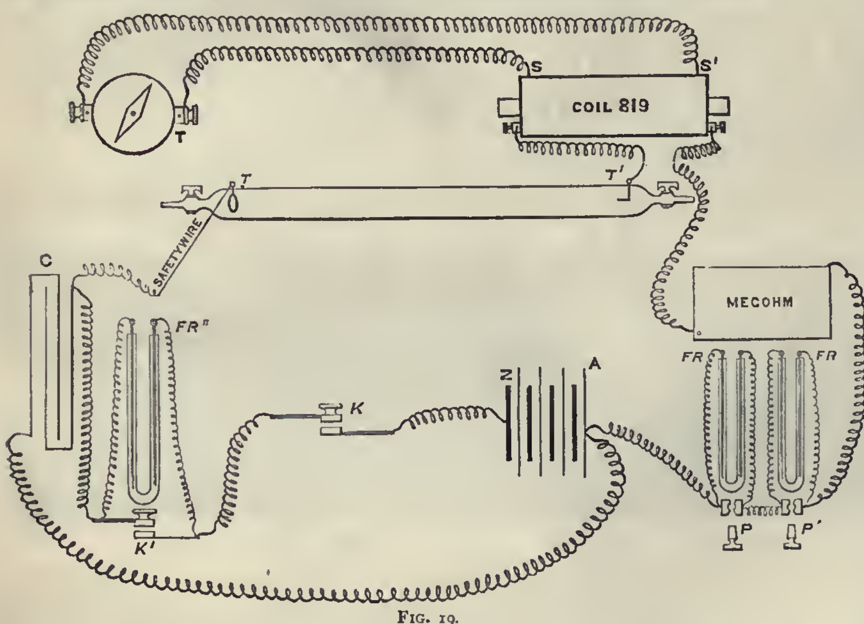

FIG. 19.

Many observations were made with coil No. 819, which we had taken to pieces several times during the course of our trials, on account of suspected leakage from the

primary to the secondary wire. It was ultimately entirely remade in February, 1878, and the secondary wire coiled on a separate ebonite cylinder to insure efficient insulation, which was accomplished.

In every case where the strata are to the eye or rotating mirror perfectly steady, slight deflections of the needle are seen; these generally indicate a resultant *direct* current (break-contact), and in the fewer number of cases an *inverse* current indicating, in the first case, a *sudden* decrease and *slow* increase of current through the tube. These deflections, though very manifest, do not amount to more than about three or four divisions of the galvanometer scale, a deflection which indicates a current of only 0·0000000023 W. At the advent or retreat of a stratum at the positive pole there is frequently produced a deviation of 300 divisions, indicating a current of 0·00000001812 W; before a stratum leaves the positive terminal or dies out on it, there is usually a tremulous motion of that stratum visible to the eye and indicated by rapid pulsations of the galvanometer.

On the suggestion of Prof. Clerk Maxwell we have recently introduced the telephone into the primary current, as shown in Fig. 20, and also in the secondary current of coil 819.

In all cases where the condenser C was discharging itself gradually through the tube, a low rustling sound was distinctly audible to sensitive ears so long as the stratification remained *apparently* perfectly steady. When the phase of confused stratification which immediately precedes extinction was reached, the sound in the telephone became very loud and rose in pitch, with some tubes becoming quite shrill. These results, therefore, confirm the conclusion already arrived at from other experiments, namely, that the discharge in vacuum tubes is intermittent; but we do not pretend that they make it manifest that stratification is *dependent* upon intermittence.

In the course of our experiments, using sometimes 11,000 cells, we have arrived at the following facts:—

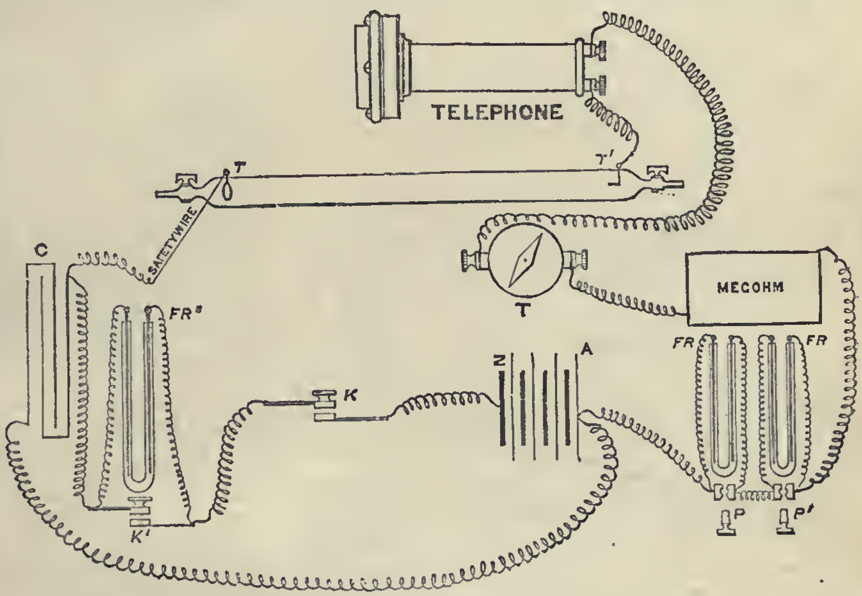

FIG. 20

1. *The discharge in a vacuum tube does not differ essentially from that in air and other gases at ordinary atmospheric pressures; it cannot be considered as a current in the ordinary acceptation of the term, but must be of the nature of a disruptive discharge, the molecules of the gas acting as carriers of electrification. The gases in all probability receive impulses in two directions at right angles to each other, that from the negative being the more continuous of the two. Metal is frequently carried from the terminals and is deposited on the inside of the tube, so as to leave a permanent record of the spaces between the strata.*

2. *As the exhaustion proceeds, the potential necessary to cause a current to pass diminishes up to a certain point, whence it again increases, and the strata thicken and diminish in number, until a point is reached at which, notwithstanding the high electromotive force available, no discharge through the residual gas can be detected.* Thus, when one pole of a battery of 8,040 cells was led to one of the terminals of tube 143, Fig. 21, which has a radiometer attached to it, the other terminal of the tube, distant only 0·1 inch, being connected through a sensitive Thomson galvanometer to the other pole of the battery (earth), the current observed was not greater than that which was found to be due to conduction over and through the glass. Although no current passed, the leading wires acting inductively stopped the motion of the radiometer, as has been observed by Sir William Grove.

3. *All strata have their origin at the positive pole.* Thus, in a given tube, with a certain gas, there is produced at a certain pressure, in the first instance, only one luminosity which forms on the positive terminal, then, as the exhaustion is gradually carried further, it detaches itself, moving towards the negative, and being followed by other luminosities, which gradually increase in number up to a certain point.

4. *With the same potential the phenomena vary irregularly with the amount of current.* Sometimes, as the current is increased, the number of strata in certain tubes increases, and as it is diminished their number decreases; but with other tubes the number of strata frequently increases with a diminution of current. If the source of the current is a charged condenser, the flow being from one of its plates through resistances and the tube to the other; then, as the potential of the condenser falls and the current diminishes, the number of strata alters; if the strata diminish in number with the fall of potential, then the stratum nearest the positive wire disappears on it, the next then follows and disappears, and so on with others; if, on the other hand, the charge of the condenser is very gradually increased, the strata pour in, one after the other, in the most steady and beautiful manner from the positive.

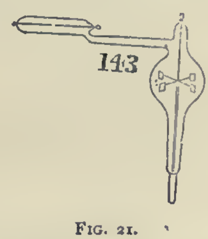

FIG. 21.

5. *A change of current frequently produces an entire change in the colour of the strata:* for example, in a hydrogen tube from a cobalt blue to a pink. It also changes the spectrum of the strata; moreover, the spectra of the illuminated terminals and the strata differ.

6. *If the discharge is irregular and the strata indistinct, an alteration of the amount of current makes the strata distinct and steady.* Most frequently a point of steadiness is produced by the careful introduction of external resistance; subsequently the introduction of more resistance produces a new phase of unsteadiness, and still more resistance another phase of steady and distinct stratification.

7. *The greatest heat is in the vicinity of the strata.* This can be best observed when the tube contains either only one stratum, or a small number separated by a broad interval. There is reason to believe that even in the dark discharge there may be strata, for we have found a development of heat in the middle of a tube in which there was no illumination except on the terminals.

8. *Even when the strata are to all appearance perfectly steady, a pulsation can be detected in the current; but it is not proved that the strata depend upon intermittence.*

9. *There is no current from a battery through a tube divided by a glass division into two chambers, and the tube can only be illuminated by alternating charges.*

10. *In the same tube and with the same gas, a very great variety of phenomena can be produced by varying the pressure and the current. The luminosities and strata, in their various forms, can be reproduced in the same tube, or in others having similar dimensions.*

11. *At the same pressure and with the same current, the diameter of the tube affects the character of the discharge and the form and closeness of the stratification.*

THE ROYAL SOCIETY OF EDINBURGH

THE goodly volume of the proceedings of this Society for the session 1877-78 witnesses to the zeal and success with which scientific problems, whether of general or of more specially local interest, are attacked by our northern *savants*.

The fascination in which the public mind has been held by those remarkable instruments, the telephone, phonograph, and microphone, here matures in fruitful study of them. Prominent among the researches referred to are those of Prof. Fleeming Jenkin and Mr. Ewing on the wave-forms of articulate sounds, as obtained from the phonograph (already described in our columns), and the thoughtful investigations of Dr. Ferguson on the indications of molecular action in the telephone, leading to the conclusion that at the sending-station the evidence of molecular action, though suggestive, is by no means conclusive, whereas at the receiving-station, the existence of molecular as well as mechanical action amounts to demonstration, and it is shown to be considerable in amount. Several striking observations in the same field are recorded by Professors McKendrick, Tait, and Forbes, Mr. Blyth, and others. In a paper on beats of imperfect harmonies, Sir William Thomson develops the theory of the phenomenon, and affirms (as a result of experiment) that in every case the ear distinguishes the two halves of the period of each beat, represented respectively by a sharp-topped and flat-hollowed curve and by a flat-topped and sharp-hollowed curve.

The Fourth Report of the Boulder Committee communicates many instructive facts, especially as regards transport of boulders. In his appended remarks Dr. Home shows reason for thinking that two notable spherical balls of marcasite found in the boulder clay at Leith, came from the westward, one from Campsie or Kilsyth (not less than thirty miles), the other from Humbie, nine or ten miles due west of Edinburgh. A geological study of the district indicates the agency of deep-sea currents loaded with ice, which flowed upon the Campsie Hills from the west-north-west, scooping out the present valley and breaking up, to a large extent, the coal strata in it. Thus some of the nodules in these strata would find their way to Leith, where they were embedded Several cases are noted in which boulders, to reach their present sites, must have crossed arms of the sea (*e.g.*, boulders in Staffa, at Appin, and in Loch Creran, from Mull, and others in Nairn, from Ross-shire). The high position of many boulders is explained by Prof. Judd's supposition, that in pliocene times there were mountains in Skye, Mull, Ardnamurchan, and even in Rum, some of which reached a height of at least 14,000 feet. In another geological paper Prof. Geikie traces out the limits of the different basins in which the old red sandstone of the British Islands was deposited, distinguishing the basins as Lakes Orcadie, Caledonia, Cheviot, Lorne, and the Welsh Lake. Dealing with the first alone, he examines the evidence for Murchison's three-fold arrangement of the old red sandstone (finding the middle division only in the north of Scotland), and describes the various districts of Lake Orcadie *seriatim*.

From experiments on suspension, solution, and chemical combination, Mr. William Durham concludes that these phenomena differ only in degree, and are manifestations of the same force. The attraction of chemical affinity is not, in all cases at least, exhausted when a definite compound is formed, but has sufficient power left to form solution or suspension compounds. The same force operating in chemical combination and solution, explains the powerful effects of solution in promoting chemical reaction and electric conductivity. Among chemical subjects treated, are the action of heat on some salts of trimethyl sulphine (Brown and Blackie), the action of chlorides of iodine on acetylene and ethylene (McGowan), and the crystallisation of isomorphous salts (Robinson).

In physiology, we note an extension of Prof. Rutherford and Messrs. Vignals' experiments on the biliary secretion, with reference to the action of cholagogues. The effects of fifty-two medicinal agents on the liver (of dogs) have been investigated, and the great majority of the conclusions are in complete harmony with the results of clinical observation, while many new facts are given to the physician.—Mr. Newman successfully imitates in a physical experiment, the function of the kidney.—Mr. Stirling furnishes some notes of the fungus disease affecting salmon.

A sketch is given by Mr. Edward Lang, of the arrangement of tables of ballistic curves in a medium resisting as the square of the velocity, and of the application of these tables to gunnery.

Without further enumeration, we may direct attention to some interesting accounts of that rare phenomenon, a white sunbow, witnessed at Edinburgh on January 10 last year.

OUR ASTRONOMICAL COLUMN

THE SATURNIAN SATELLITE HYPERION.—Prof. Asaph Hall has investigated the elements of this satellite, first from thirty of the best observations made at Washington in 1875, and again from thirty observations by Mr. Lassell at Malta, in 1852-53. In the former case the approximate elements in *Astron. Nach.* No. 2137 were used in the calculation of equations of condition, which were solved by the method of least squares. The resulting orbit is as follows:—

Passage through perisaturnium, 1875, Oct. 27·8380 Greenwich M.T.

Perisaturnium	$172^\circ\ 59'{\cdot}7$	For 1875,82. Referred to the plane of the earth's equator.
Ascending Node ...	$120\ \ 12{\cdot}0$	
Inclination	$6\ \ 12{\cdot}1$	
Excentricity	0·11885	
Semi-axis major	$216''{\cdot}56$	

Assuming these values for the node and inclination, Mr. Lassell's observations were discussed and gave the elements:—

Passage through perisaturnium, 1852, Nov. 17·5208 G.M.T.

Perisaturnium	... ...	240° 10′·9
Excentricity	... ...	0·12011
Semi-axis major	...	217″·05

It will be seen that the position of the perisaturnium had undergone a great change in the interval between the above epochs: the rapid motion of the line of apsides has been known for some time past to those who have attempted the determination of elements of Hyperion. Prof. Hall had at first supposed this motion direct, but he now adopts the smaller retrograde motion, and so finds for the motion of the line of apsides in a Julian year,—2°·92862. If we assume that 394 revolutions of the satellite had been performed in the interval between the epochs (8379·3172 days), the anomalistic period is found to be 21·2673026 days.

Prof. Hall thinks that the next step must be the calculation of the action of the great satellite Titan on the motion of Hyperion, a work which he hopes to be able to undertake. Not only is there a near approach of the orbits of the two bodies, but it would appear that Hyperion is moving in a larger orbit, than would correspond to the assigned period and Bessel's mass of Saturn. There is a probability that the approximation of the two satellites may be, at certain times, very close indeed. If we bring up Bessel's elements of Titan to 1875, and compare them with the above elements of Hyperion for the same year, we find an exceedingly near approach of the two bodies, when the position of the perisaturnium of Hyperion corresponds to that of maximum distance of Titan, and though uncertainty in the elements may affect the result, it is sufficiently evident that the motion of Hyperion cannot be followed satisfactorily without a knowledge of the action of Titan. Prof. Hall remarks that in 1882 it may be possible with the Washington refractor to follow Hyperion completely round its primary, as was done by Mr. Lassell at Valetta in 1852, and that from that time until 1888 it should be carefully observed.

THE OXFORD UNIVERSITY OBSERVATORY.—The report of the Savilian Professor of Astronomy, as Director of the University Observatory at Oxford, has been issued, for the year ending on the 4th of the present month. The $12\frac{1}{4}$ inch refractor has been in constant use in the determination of accurate positions of about 40 stars in the Pleiades, partly with the view of ascertaining the proper motions by comparison with the observations of Bessel half a century ago, and partly with the intention of comparing the micrometrical measures with those of the costly heliometer. The results will appear in Part II. of the Oxford Observations, and we may remark that the Savilian Professor will have a recent standard for comparison in M. Wolf's elaborate work on the Pleiades, (*Description du Groupe des Pleiades* in the Paris *Annales*, t. xiv.), to which he has not made allusion in the report. The De la Rue reflector has been employed in taking photographs of the moon, and nearly three hundred have been secured. With the view of ascertaining how far these photographs can be relied upon for accurate measurements, micrometrical measures of the shadows of several prominent lunar mountains were made with the refractor, simultaneously with the taking of photographs with the reflector; the latter being then measured in the De la Rue engine, it was found that the telescopic and photographic results were in close accordance, indeed within the limits of the unavoidable errors of observation. The Professor adduces a still further proof of the reliability of celestial photography in this direction, in the close accordance of the moon's semi-diameter, as measured and computed from sixteen of the Oxford photographs with Hansen's value adopted in the *Nautical Almanac*; the difference is only 0″·12. Amongst the other miscellaneous work of the Observatory during the past year, the periodical comets of Tempel (1873 July) and Brorsen have been well observed. In the Lecture Room discourses have been delivered on the Astronomy and Astronomical Instruments of Ptolemy and Hipparchus, on the Physical Libration of the Moon and on Solar Physics.

The obligation under which this institution remains to the great liberality and scientific spirit of Dr. De la Rue is well known. The salary of the photographic assistant has been defrayed by him during a period of four years, this subsidy, a most important one to the rising Observatory, terminating in December next. The necessary provision for the future effective conduct of the Observatory is under the consideration of the University Commissioners, subject to the final judgment of Convocation. It is suggested by the Savilian Professor in his report, that for the next few years a sum of 600*l.* annually may suffice to cover all necessary expenses. The desirability of an early publication of results, in the actual state of Astronomical Science, appears to be fully appreciated in the Oxford establishment: part I. of the Observations containing the work to December 1877 was published in the spring of 1878.

A NEW COMET.—A pretty bright telescopic comet was detected, apparently on the 16th inst., by Mr. Lewis Swift, of Rochester, N.Y. Prof. Winnecke observed it at Strasburg on June 21, and found its position at 11h. 38m. 46s. mean time in R.A. 2h. 47m. 31·1s., Decl. 64° 29′ 5″; daily motion in R.A. trifling, that in Decl. about one degree towards the north; diameter about three minutes.

GEOGRAPHICAL NOTES

AT the meeting of the Royal Geographical Society on Monday evening, after a feeling allusion by the Earl of Northbrook to the loss sustained by the Society by the death of Mr. R. B. Shaw, British Resident at Mandalay, who was well-known for his excellent geographical work in Eastern Turkistan, &c., some reports were read which had recently been received from Mr. Keith Johnston, the leader of the East African Expedition. The first was an exceedingly interesting account of his preliminary trip from Zanzibar to the Usambara Hills, and the second was a memorandum of information obtained regarding routes between Dar-es-Salaam and the north end of Lake Nyassa. It is no exaggeration to say that the latter document contained more real geography than many travellers contrive to collect in the course of a long journey, and it confirms the impression that Mr. Johnston, if he be spared, will, on his return from the interior, furnish us with a most admirable and accurate account of the country traversed, the greater part of which is at present absolutely unexplored. The Secretary afterwards read letters from Mr. Johnston and Dr. Kirk, H.M.'s Consul-General at Zanzibar, announcing the final start of the expedition for the interior, under the most favourable circumstances. Mr. Johnston has with him one European assistant and 138 porters, who have been carefully selected with the aid of Chuma, Livingstone's old follower, who also accompanies the party.

THE last sitting of the Geographical Society of Paris, was devoted to a lecture given by M. Cosson to prove (1) that M. Roudaire's contemplated Algerian sea would not improve the climate of the Sahara; (2) that in case any alteration were possible it would be detrimental to the health of the inhabitants; (3) that it would create dissatisfaction amongst the Tunisian and Algerian tribes, and even Algerian colonists; and (4) that it would have no effect in attracting to Algiers the trade of the Soudan. Commander Roudaire not having been invited to answer the charges proffered against his scheme the discussion was adjourned, but several members warmly protested against the assumption brought forward by M. Cosson, and tried to rebut his assertions.

CAPTAIN R. H. NAPIER, R.N., has communicated some useful hydrographic notes to the Hong Kong

Government Gazette respecting the Chinese island of Hainan and the Gulf of Tongking. The following are the positions determined:—Hoihow Fort A, lat. 20° 3′ 13″ N. long. 110° 19′ 3″ E.; Pakhoi Customs flagstaff lat. 21° 29′ N. long. 109° 6′ 6″ E.; Guie-chow Island summit lat. 20° 1′ 15″ N., long. 109° 6′ 31″; Cape Cami lat. 20° 11′ 58″ N., long. 109° 54′ 57″ E.; North Taya Island, lat. 19° 58′, N., long. 111° 16′ E.

IT is stated that Major Serpa Pinto will come to London soon to give a lecture on his recent journey across Africa.

SIR SAMUEL BAKER, who has spent the last six months in traversing the island of Cyprus in a gipsy waggon, carefully observing all the natural phenomena, is engaged in writing a book to be called "Cyprus as I saw it in 1879," which will be published by Messrs. Macmillan and Co.

THE newly published *Bulletin* of the Belgian Geographical Society contains two papers by their indefatigable vice-president, Colonel Adan, one of which is entitled "Sur la Participation des Officiers aux grands Travaux de Géographie Scientifique." M. Greiner contributes some notes on the cultivation of tobacco. We are glad to observe that considerable space (upwards of 29 pp.) is devoted to "Chronique Géographique," and much care is evidently bestowed on the collection of matter. Among these notes there is one of much interest on the proposal for connecting Liége and Escaut by means of a canal.

THE ever-interesting *Monatschrift für den Orient* for June contains several papers of varied interest. Georg v. Gyurkovics writes on the trade politics of Bulgaria; Dr. G. Schweinfurth sends from Cairo some notes on Rohlf's last exploring journey in Tunisian territory. In view of the new relations of Germany with the Samoan Islands, Dr. Hubbe-Schleiden's article on Germany in the Pacific is well-timed, and so from another point of view is Herr Josef Hras's letter from Shanghai on the Kulja Question. Under the title of Tsin and Ta-Tsin Count Schweiger-Lerchenfeld contributes a learned paper on the old trade routes of the Chinese.

THE principal paper in the June number of Petermann's *Mittheilungen* is a long account by M. A. Woeikoff of his travels in Yucatan and the south-east provinces of Mexico in 1874. As might be expected from so accomplished and experienced a traveller, the paper is very comprehensive and full of original observations on the many interesting features of the region visited. Dr. P. Jonas, contributes the conclusion of a paper begun some time since on Venezuela, describing a journey he made through the Llanos to the Apure. Dr. Emin Bey continues his valuable narrative of his journey from Mruli to the chief town of Unyoro, and Herr B. Hassenstein describes the north coast of Siberia between the mouth of the Lena and Behring Strait.

NEWS, dated February 23, have just been received at Vienna from the Hungarian Expedition travelling in China under the leadership of Count Bela Szechenyi. Count Szechenyi, Lieutenant Kreitner, and Herr L. Loczi, started from Sia-an-Sen, and after a very laborious march of 20 days, during which they had to pass several mountain chains measuring more than 3,000 metres in height, finally arriving at Lan-Chan-Sen. The province of Shen-Si, where, as in Shan-si and Konan a famine was raging, showed decay and ruin everywhere; the same state of things prevailed in the province of Kiang-Su. The long rebellion of the last years has left these unenviable traces. The expedition intended to leave for Su-tshou on February 14, on which march they would have to pass the Hoang-ho river.

AT the last meeting of the Berlin Geographical Society the President, Dr. Nachtigal, communicated the latest reports received from the German African travellers. Engineer Schütt has started on his journey into the interior and believes that he has now succeeded in overcoming all the difficulties which at first presented themselves to his further progress towards the East and North; he now intends entering the country of the Adjellengo tribe. Dr. Buchner was detained at Cassenge through the rainy season. He intended leaving for the interior at the beginning of May. Dr. Gerhard Rohlfs has had much to endure from the fanaticism of the natives at Djalo, where he is still staying, and has also been unable to obtain a guide through the Wadai desert on account of the unfriendliness of the Bengasine Government. His companion Dr. Strecker has returned to Bengasi in the meantime in order to attempt to make the Government more favourably disposed towards Dr. Rohlf's undertaking.

ON June 3rd the Dutch North Polar Expedition sailed from Amsterdam on board the "Willem Barends." The ship is equipped with all necessaries for 10 months.

A CARAVAN from Abyssinia has arrived at Marseilles, being destined for the acclimatization garden of Paris. It is composed of 15 men, 4 women, 2 children, 32 camels, 4 oxen, 2 zebras, 4 elephants, 8 ostriches, asses, and horses from Dongola and Abyssinia.

THE Batavian Society of Arts and Science have published in English in a recent volume of their Transactions some curious notes on the Malay Archipelago and Malacca, which have been compiled from Chinese sources by Mr. W. P. Groeneveldt.

NOTES

WE regret to say that although all critical symptoms have disappeared, Sir Wyville Thomson is not regaining strength so fast as was at first hoped. It will be some time still before he can attend to business letters. In the meantime all communications connected with *Challenger* matters should be addressed either to Mr. John Murray, his Principal Assistant, *Challenger* Office, 31, Queen Street, Edinburgh, or his Secretary, Mr. George Leslie, University, Edinburgh.

PROF. A. R. RAMSAY has been elected a Foreign Corresponding Member of the R. Accademia dei Lincei. At the same time Drs. vom Rath and Donders were elected to a similar honour.

PROF. AUGUST KROENIG, the author of "Grundzüge einer Theorie der Gase," died at Berlin on June 5, after a year's illness.

IN the death of Prof. Carl Theodor Ludwig Neubauer, to which we briefly alluded in our last number, German chemistry has lost one of its most accomplished specialists. Neubauer was born at Lüchow in 1830. After a fair high-school education and some experience as an apothecary he entered, at the age of twenty-three, the laboratory of the famous analytical chemist, Fresenius, at Wiesbaden, in the capacity of assistant. In 1856 he commenced his pedagogical career as privat-docent, and received in 1864 a professor's chair. At an early period he became a recognised authority in various branches of analytical, agricultural, and physiological chemistry, and especially in the chemistry of the urine, to which he has always devoted his chief attention. His researches in this department embrace the detection of various normal and abnormal constituents previously unknown, and the elaboration of exact methods for the qualitative and quantitative analysis of urine. The manual of Neubauer and Vogel on this subject, which reached its seventh edition in 1876, is regarded as the most exhaustive and complete work of the kind. The various higher derivatives of the urea group occurring in nature, such as xanthin and kreatin, were also made the base of careful research. Neubauer's investigations into the chemistry of wine have likewise

been productive of valuable results, and his work on this subject, which appeared in 1870, has been successively rendered into English and Italian. No small portion of his time was devoted to the perfection or invention of new general analytical methods, and in this connection mention should be made of his careful, critical reviews of the progress of analytical chemistry, which have formed so important a part of Fresenius' *Zeitschrift für analytische Chemie* since its foundation in 1862. Neubauer was honoured successively by calls to professorships in Zurich, Tübingen, and Erlangen, all of which he declined; preferring the more quiet, if somewhat limited field offered to his activity in Wiesbaden.

THE Council of the Society of Arts have awarded the following medals for papers read during the past session of the Society:—To Mr. Alfred Haviland, M.R.C.S., for his paper on the distribution of disease popularly considered; to Mr. John Holloway for his paper on a new application of a process of rapid oxidation, by which sulphides are utilised as fuel; Mr. Conrad W. Cooke for his paper on Edison's new telephone; Mr. Thomas Wardle for his paper on the wild silks of India, especially Tussah; and Dr. Wm. Wallace, F.R.S.E., for his paper on gas illumination.

MR. JOHN FISKE, whose able work on "Cosmic Philosophy" is familiar to our readers, is just now in England, and has put in the hands of Messrs. Macmillan and Co., for early publication, a volume of essays on Darwinism and other subjects of a kindred nature.

As our readers know, there are one or two vacant seats in Parliament for which there is already busy competition throughout the country. Sir John Lubbock, in a letter to the *Times*, suggests that one of them be devoted to science. "As the time is approaching," he writes, "when the distribution of the vacant seats will claim the attention of Her Majesty's Government, I would suggest whether one of them might not with advantage be allotted to the Royal Society. The members of that Society are all men eminent in their respective branches; they would form a constituency second to none in the United Kingdom, and would certainly send a representative who would be a valuable addition to the House of Commons. The agricultural, manufacturing, and commercial interests, the military and naval services, and the law are all strong in the House of Commons; literature is represented by the University members; but science, the practical importance of which is daily increasing, has no voice in the deliberation of the nation. The proposal which I venture to suggest would likewise have the merit of introducing some additional variety into our representative system. The alternative would be that there should be one more member for a great borough or a populous county. Lastly, I may add that the constituency, though not large, would be by no means among the smallest in the United Kingdom."

WE are requested to explain that the paragraph in the Astronomer-Royal's report relating to the performance of the Westminster clock, referred to its going during the exceptionally severe weather of the past winter. On the average of the whole twelve months it would appear that the present is the best year but one of the clock's performance, *it having been within one second of true time on* 80 *per cent.* of the days of observation.

ONE of the most interesting novelties in the Berlin Exhibition is the construction of an electrical railway by Siemens and Halske. The electrical power is supplied by a dynamo-electric machine worked by a steam-engine to another dynamo-electric machine, which works the wheels of an electric locomotive. The length of the way is 200 metres, the velocity three metres per second; the number of waggons three, and passengers twenty. The same experiment will be tried at the Scientific Exhibition at the Paris Palais de l'Industrie, with Marcel Deprez's motor, which is very promising. A new model has been constructed, weighing seven kilograms, and with twelve Bunsen elements can give a man-power. This model of Marcel Deprez's is exhibiting now at Lille, on the occasion of one of the ascents of the Aëronautical Academy. It is hoped that it will have force enough to work an aërial helix for ascending and descending without any sacrifice of ballast and escape of gas.

AN interesting ceremony has just taken place at Paris. The pupils of the École Centrale, which was founded at Paris in 1829 by MM. Dumas, Lavallè, Perdonnet, and a number of engineers for promoting education in practical science, has celebrated the fiftieth anniversary of that event. The new institution was so prosperous that a few years ago it was purchased by the Government and made a public institution. It would be difficult to give an idea of the number and importance of the positions occupied by the pupils of the École Centrale in French industry. It may be said without any exaggeration that they have been employed in the construction of almost every railway in France and perhaps on the Continent. Most of the French jurymen to the several international exhibitions have been educated there. M. Dumas, who enjoys excellent health, and may expect as long a career as his friend, M. Chevreul, is the only founder alive, and consequently was the hero of the celebration. On June 20 he was received at the Hotel of the Rue Couture St. Gervais, where the school is situated, by the members of the Conseil de Perfectionnement, directors and pupils, who offered him a testimonial of gratitude. On June 21 a great meeting was held at the Trocadero, in the large hall, under the presidency of M. Tirard, Minister of Agriculture and Commerce, M. Dumas sat at his right. M. Dumas, who is an eloquent and powerful speaker, delivered a most impressive address. He spoke on the obstacles which the founders met with, and after having explained how they had managed to win success, he exclaimed, "We had faith, and you proved that we were right in having it." At seven o'clock the pupils met at the Continental Hotel, having invited MM. Dumas, de Lesseps, Boisson, vice-president of the Chamber of Deputies, and a number of leading railway engineers, and others.

THE memory of the great Swedish botanist Linné (Linnæus) is about to be honoured in a fitting manner by his countrymen. In the State Budget for 1880 a sum of 80,000 Swedish crowns is set aside for the purchase of the Hammarby estate, near Upsala, which originally belonged to Linné, as well as of a quantity of furniture he once possessed. This new Linné Museum will be placed under the superintendence of the Rector of Upsala University.

AT the last meeting of the Geological Society, Prof. Prestwich announced that the next International Geological Congress will be held at Bologna in September, 1881, and that the President of the Committee, Prof. Capellini, had written, requesting co-operation on the part of the Geological Society and its Fellows. Among the matters which would be brought forward at this Congress would be the unification of geological nomenclature and the symbols used in geological mapping.

A ZOOLOGICAL station similar to that at Naples is about to be established at Messina.

WHAT with its museums and learned societies, the Berlin *Times* correspondent writes, Berlin is fast becoming a highly-favourable centre for the study of ethnology. Some time ago a tribe of Esquimaux attracted large crowds to their quarters in the Zoological Gardens. A family of Patagonians is waiting impatiently to be introduced by Prof. Virchow to the Anthropological Society to-morrow evening, while the latest phase of

enterprise in this respect is nothing more nor less than the importation of half-a-dozen live Zulu Caffres!

Dr. Elliott Coues's Bibliographical Appendix to his "Birds of the Colorado Valley" has proved, the New York *Nation* states, the occasion of one of the highest compliments paid of recent years to American science. A memorial has been addressed to him, signed by Prof. Flower, Huxley, Darwin, Mivart, Wallace, Gould, Sclater, Günther, Newton, and numerous other eminent English zoologists, declaring his special fitness to undertake a complete Bibliography of Ornithology, and urging the importance—the indispensableness, in fact—of his visiting the older European libraries in order, for the non-American portion, to consult every work mentioned at first hand. They express the hope that the same official liberality which has permitted Dr. Coues to remain in Washington for the prosecution of his bibliographical labours, will grant him leave of absence and provide the means for carrying out the wishes of the memorialists; and they promise him a warm welcome to England and every assistance in their power. Such a call, the *Nation* thinks, ought to be irresistible, and has every reason to believe that it will be heeded.

The fine collections, consisting mainly of insects, of Dr. A. Boucard, the results of many years' gathering from all parts of the world, are for sale.

Prof. Dubois-Reymond showed in 1859 that the polarisation of amalgamated zinc electrodes in aqueous solution of zinc sulphate was, with use of very weak polarising currents, extremely small, and he called such a combination "unpolarisable." This mere approximation seems to have been since misapprehended, and it has been quite overlooked that the non-polarisability is quite lost with increasing strength of current. In experiments lately made by Herr H. F. Weber, in order to test the laws of hydro-diffusion (*Vierteljahrsschrift der naturf. Ges. zu Zurich*, vol. xxiii.), it has appeared that between amalgamated zinc plates in zinc sulphate solution, a very definite polarisation occurs, and may even be employed as a method of measurement for the progress of the diffusion. This polarisation, however, is not the consequence of electrolytic processes at the electrodes, but of changes of concentration in the layers of zinc sulphate solution in contact with the electrodes, produced by passage of the ions. A sample experiment with amalgamated zinc plates, not placed vertically opposite each other, but horizontally, one over the other, proves the correctness of this assertion.

The Scinde *Civil and Military Gazette* describes a remarkable hailstorm that burst over Hala on May 8. The storm, we believe, was purely local. It commenced about four o'clock in the afternoon, coming up from the north-west with a strong wind and preceded by a heavy dust-storm. On the first burst the hailstones were, in form, flattened cones, with a central belt of snow-like ice and outer belts of clear ice. After the first fall of hail and rain the storm swept on to the south. There was a short lull, when the storm, working apparently in a circle, again broke over Hala, this time coming up with the wind from the south. Thunder and lightning were now continuous, the thunder, in fact, never ceasing for an instant, and a fall of enormous hailstones took place. These, unlike those of the first fall, were spherical in shape, snow-like in appearance, and in size larger than the largest marble—one, whose diameter was estimated, being an inch and a half across—as large, that is, as an ordinary hen's egg. For some time after the storm the ground was thick and white with the monstrous hailstones; except under trees, where beds of leaves and branches lay, broken and beaten off from above. The storm continued from first to last for about one hour and a half, and went off towards the north-east.

The *Henry Giffard* captive balloon has been inspected by the public authorities of Paris, and opened to the public for ascents.

In a recent medical report from Chinkiang, on the Yangtsze-kiang, in the neighbourhood of which there are immense depôts of salt, Dr. A. R. Platt mentions that he has observed a form of skin disease, presenting all the essential symptoms of ecthyma, yet with others that do not properly belong to that affection, and all so aggravated as to make the variety unique in his experience. It appears to be peculiar to workers in salt, judging from the four cases Dr. Platt has seen, all of whom were females, and all engaged in salt smuggling. They did not hesitate to attribute their condition to their daily habit of carrying large quantities of salt in girdles next the skin, so as to be concealed by their clothing, though, as the eruption first appeared on the hands, they were more inclined to lay it down to the preparation of the packages than to the transportation, and informed Dr. Platt that it was quite common among the people at the salt stations whence they procured their illicit supplies. Dr. Platt in his report furnishes a detailed account of the symptoms exhibited in the cases referred to, and of the line of treatment which he adopted with very satisfactory results.

The Municipal Council of Paris has adopted a proposal made by M. de Villiers, Chief Engineer of Ponts-et-Chaussées, for establishing at the Trocadero a stone which will be the zero point of levelling for Paris and the Seine Department. It is stated that the Minister of Public Works will order such a stone to be erected in the chief city of each department. All these stones will be related to each other by the Bourdaloue levelling which was made many years ago, and which takes for zero the mean level of the Mediterranean at Marseilles; this last is supposed, of course, as invariable.

The French Minister of Agriculture has published a report on the agricultural educational institutions of France, which shows an immense variety. The head establishment is the École Supérieure of Agriculture at the Conservatoire des Arts et Métiers. Next to this institution are the regional schools of agriculture as at Grignon and several other places. A number of special subjects have schools devoted to them, as the veterinary school at Alfort, schools of gardening at Versailles, schools of draining and irrigation in Brittany; a school of pisciculture has been established at Huningue, which was lost to France with Alsace; there are also schools for sheep-rearing, vine-growing, &c. The Vincennes farm and some others are devoted to experimental agriculture. Farmers' schools are located in several parts of the country, and kept by private individuals at their own expense, with a subsidy from townships or departments for training young men in several agricultural specialties. We may also consider as a part of these institutions the School of Arboriculture in the Luxembourg, and the School of Insectology in the same garden; although they have no registered pupils, they have lecturers and museum and experimental grounds at their disposition.

A translation of Fau's "Anatomie Artistique," by Dr. Carter Blake, of Westminster Hospital, will shortly be published by Messrs. Baillière, Tindall, and Cox.

A Russian paper gives an account of a plague of locusts near Elisabetpol, which forced a detachment of troops on the march to retrace their steps. They settled so thick on the soldiers' faces, uniforms, and muskets, that the major, driven to desperation, ordered firing at them for half an hour, but this produced no effect, and a march back was ordered. The swarm covered an area of thirty-five square versts.

A swarm of butterflies passed over Worms on the 13th and 14th, proceeding from north-west to south-east.

A JAPAN paper mentions a curious instance of Japanese thrift at Osaka. The paper made at the mill there is mostly manufactured from blue rags, and the water in which they are boiled has hitherto only poisoned the watercourses; henceforth it is to be saved and the indigo extracted from it.

THE Manchester people have entered a fresh protest against centralisation by the publication of the *Manchester Magazine*, No. 2 of which lies before us, and devotes a fair proportion of its space to articles in science. Mr. L. H. Grindon writes on the art of distinguishing trees, and Mr. Angell on the Manchester Science Lectures. Prof. Osborne Reynolds writes on the Manchester Philosophical Society, and there are articles on Stargazing, the Phonograph, the Weather, &c. Indeed the bulk of the magazine is scientific.

THE University Library at Strassburg has, according to the latest news, now reached the total of 470,000 volumes.

WE have received a very favourable Report of the Auckland (N.Z.) Institute for 1878-9. A considerable number of papers bearing on the natural history of New Zealand have been read during the session.

THE additions to the Zoological Society's Gardens during the past week include two Macaque Monkeys (*Macacus cynomolgus*) from India, presented respectively by Mr. G. T. Close and Miss E. Cattlin; a Garnett's Galago (*Galago garnetti*) from East Africa, presented by Mr. F. W. Barff; two African Civet Cats (*Viverra civetta*) from Africa, a Kinkajou (*Cercoleptes caudivolvulus*) from Demerara, presented by Lieut. M. B. Salmon, Indian Staff Corps; two Egyptian Gazelles (*Gazella dorcas*) from Egypt, presented by Commander J. Pratt, s.s. *Java*; a Persian Gazelle (*Gazella subgutturosa*) from Persia, presented by Mr. C. H. Watts; three Hyacinthe Porphyrios (*Porphyrio hyacinthinus*) from West Africa, two Egyptian Kites (*Milvus ægyptius*) from Egypt, presented by Mr. A. Bells; a greater Sulphur-Crested Cockatoo (*Cacatua galerita*) from Australia, presented by Mr. J. W. Taylor; a Slender-billed Cockatoo (*Licmetis tenuirostris*) from South Australia, presented by Mr. Geo. Wood; a Ring-necked Parrakeet (*Palæornis torquatus*) from India, presented by Mr. E. F. Carey; four Australian Wild Ducks (*Anas superciliosa*) from Australia, presented by Messrs. A. H. Jamrach and Charles Rice; two Pied Wagtails (*Motacilla yarrelli*), British Isles, presented by Mr. A. F. Wierner; a Common Badger (*Meles taxus*), British Isles; a Ceram Lory (*Lorius garrulus*) from Moluccas, an American Robin (*Turdus migratorius*) from North America, a West African Python (*Python sebæ*) from West Africa, a Reticulated Python (*Python reticulatus*) from Molucca, eleven Spotted Salamanders (*Salamandra maculosa*), European, deposited; a Beech Marten (*Martes foina*) from Russia, a Brazilian Tanager (*Ramphocœlus brasilius*) from Brazil, twenty Spotted Salamanders (*Salamandra maculosa*), European, purchased; a Collared Fruit Bat (*Cynonycteris collaris*), two Jameson's Gulls (*Larus jamesoni*), bred in the Gardens.

THE NATURAL HISTORY MUSEUM

THE following memorial has been recently presented to the Earl of Beaconsfield:—

To the Right Hon. the First Lord of the Treasury

My Lord,—In accordance with a resolution adopted by the General Committee of the British Association for the Advancement of Science at their last meeting, the Council of the Association beg leave to call your attention to the following circumstances.

1. In their fourth Report, presented to Parliament in 1874, the Royal Commission on Scientific Instruction and the Advancement of Science, having fully considered the present state of the Natural History Departments in the British Museum, and taken evidence thereon from the principal scientific authorities of the country, state that they have come to the conclusion "that the objections to the present system of government of the British Museum by a Board of Trustees as at present constituted, so far as relates to the Natural History Collections, are well founded, and that they have been unable to discover that the system is attended by any compensating advantages." They, therefore, recommend:— "(1) That the occasion of the removal of these collections to the new buildings now being erected at South Kensington for their reception, be taken advantage of to effect a change in the governing authority and official administration of that division of the Museum. (2) That a director of the National Collections should be appointed by the Crown, and should have the entire administration of the establishment, under the control of a Minister of State, to whom he should be immediately responsible, and that the keepers of collections should be responsible to the director. That the appointments of keepers and other scientific officers should be made by the Minister, after communication with the Director and with the Board of Visitors (hereinafter referred to). And that the Director should prepare the estimates, to be submitted, after consultation with the Board of Visitors, for the approval of the Minister. (3) That the present superintendent be the first director. (4) That a Board of Visitors be constituted. That the Board be nominated in part by the Crown, in part by the Royal and certain other scientific Societies of the metropolis, and, in the first instance, in part also by the Board of Trustees; the members to be appointed for a limited period, but to be re-eligible; and that the Board of Visitors should make annual reports to the Minister, to be laid before Parliament, on the condition, management, and requirements of the Museum, and should be empowered to give him advice on any points affecting its administration."

2. Exactly the same view as to the desirability of effecting a change in the government of the Natural History Collections was taken in a memorial presented to the then Chancellor of the Exchequer in 1866, and signed by the Presidents and other well-known members of the Royal, Linnean, and Zoological Societies, a copy of which is appended hereto.

3. Notwithstanding these expressions of opinion, in which nearly all the leading naturalists of the day fully concur, an Act was passed at the close of the last session of Parliament by which the Trustees of the British Museum have been authorised to transfer the Natural History Collections into the new building at South Kensington, without making any change whatever in the present mode of their administration.

4. The Council of the British Association feel that it is not necessary for them to press upon the Government the arguments for the changes in the administration of the Natural History Collections which have been so amply stated by the Commissioners in the Report above-mentioned. The Council think it sufficient to call the attention of the Government to the fact that the provisions of the act are directly at variance with the recommendations of the Royal Commissioners.

5. As, however, a fresh application to Parliament will be necessary in order to defray the expense of the removal of the Natural History Collections from their present situation to South Kensington, the Council of the British Association beg leave to point out to H.M. Government that the question of the administration of the Natural History Collections is one of the utmost importance as regards the future progress of Natural History in this country, and to urge upon them to take the opportunity which will thus present itself of effecting the alterations in the mode of administration of the Collections recommended by the Royal Commission. We have the honour to be, your Lordship's most obedient servants,

The Council of the British Association
for the Advancement of Science

Signed, for the Council, W. SPOTTISWOODE, *President*
DOUGLAS GALTON, P. L. SCLATER, } *Secretaries*

COPY OF A MEMORIAL PRESENTED TO THE RIGHT HON. THE CHANCELLOR OF THE EXCHEQUER

To the Right Hon. the Chancellor of the Exchequer

London, May 14, 1866

SIR,—It having been stated that the scientific men of the Metropolis are, as a body, entirely opposed to the removal of the Natural History Collections from their present situation in the British Museum, we, the undersigned Fellows of the Royal, Linnean, Geological, and Zoological Societies of London, beg leave to offer to you the following expression of our opinion upon the subject:—

We are of opinion that it is of fundamental importance to the progress of the natural sciences in this country that the administration of the National Natural History Collections should be separated from that of the Library and Art Collections, and *placed under one officer, who should be immediately responsible to one of the Queen's Ministers,*

We regard the exact locality of the National Museum of Natural History as a question of comparatively minor importance, provided that it be conveniently accessible and within the Metropolitan District.

SCIENTIFIC SERIALS

THE *Archives des Sciences physiques et naturelles* (May, 1879) contain the following more important papers:—Geological review of Switzerland for the year 1878, by M. Ernest Favre (continuation).—On the lake-dwellings of the Swiss lakes, by Dr. F. A. Forel.—On the rotatory power of isocholesterine, by E. Schulze.—On the existence in a gaseous state of nitrous anhydride and nitrous acid, by G. Lunge.

The Rivista Scientifico-Industriale (No. 10, 1879) contains the following articles:—On a new instrument to study microseismic phenomena, by Prof. Giovanni Mugna.—On the regress canals for the filling of ponds, by Francesco Cagnacci (3 plates).—On the present state of Mount Vesuvius, by Prof. Semmola.—On the blue colours in manufacture of porcelain, by V. Joclet.

SOCIETIES AND ACADEMIES

LONDON

Linnean Society, June 5.—Prof. Allman, F.R.S., president, in the chair.—Attention was called to an article on Cinchona in India, by Mr. J. E. Howard. *Calisaya Ledgeriana* is shown to yield excellent results, as much as 10 per cent. of quinine, and of excellent quality, being obtained.—Prof. Parker read a memoir on the structure and development of the skull in the Urodelous amphibia. Several forms are here worked out, the Spotted Salamander serving as a type. Some of the so-called skin bones appear early, other investing bones appear later, and the investing cartilaginous roof of the nose comes after the ear capsule cartilages. Some Urodela show a stapes absent in Ceratodus and Lepidosiren. The transformations of the Anoura are carried on in the plastic larva and young to a greater extent than in the Urodela.—A paper on the Lichens collected during the English Polar Expedition of 1875–76, by Prof. Fries, of Upsala, was communicated by Sir J. D. Hooker. In Dr. Hayes's Arctic journey lichens probably were not brought away from a more northerly position than 78° N. lat., but Julius Payer, in the German Expedition, with certainty obtained specimens at Cape Fligely, 82° 5′ N. lat. With the exception of these last, but three species of lichens hitherto have been published as found beyond 81° N. lat. Thus considerable interest is attached to those got under Capt. Sir G. Nares by Capt. Feilden, of the *Alert* and Mr. Hart of the *Discovery*. As these vessels wintered in different quarters, the localities where the lichens were obtained correspondingly are more numerous, thus adding to their value as indicative of vegetable life in the frozen regions. Mr. Hart, got his at thirteen stations, Discovery Harbour, 81° 42′ N. lat., being the most northern; Capt. Feilden records twelve stations, Westward Ho Valley, 82° 41′ N. lat. being the limit. But Lieut. Aldrich gathered *Gyrophora cylindrica* on the shore of the "Palæocrystic Sea," the northernmost spot trodden by man, viz., Cape Columbia, 83° 6′ 30″ N. lat. Prof. Fries notes that the so-called "fruticolous" and "foliaceous" lichen species are feebly represented, doubtless accounted for by the severe climate, but seemingly at variance with the presence of musk oxen; added to which the reindeer moss is absent. This anomalous circumstance of the presence of large ruminants and deficiency of their usual lichen food, Capt. Feilden explains by stating that the musk ox in Grinnel Land does not feed on lichens, but on mosses and grasses. The same officer has also pointed out that the lichen growth curiously enough increased in size of species with increase of altitude. Prof. Fries concludes that, without the least credit being given to an open Polar sea (existing, no doubt, only in fancy), lichen vegetation may exist at the very Pole, if only land be there, and occasionally free from snow or ice. Among the series obtained in the Expedition, save a very few, all the forms of lichens of over 100 are already known. The abstract of a fourth contribution to the Mollusca of the *Challenger* Expedition, by the Rev. R. Boog Watson was read. This dealt with the Trochidæ and Turbinidæ.—The Secretary also read a communication on a remarkable new form of Helvella, this fungus being described by Mr. W. Phillips.—Mr. C. B. Clarke summarised a lengthened memoir by him, viz., a "A Review of the Ferns of North India." He showed that many of the localities given by Dr. Wallich, and doubtfully received by botanists were doubtless correct.—Mr. A. D. Michael was elected a Fellow of the Society.

Zoological Society, June 17.—Prof. W. H. Flower, F.R.S., president, in the chair.—Mr. Sclater exhibited a skin of *Ara glauca*, from Mr. Boucard's collection, obtained at Corrientes, and stated that having compared it with the *Ara* now in the Gardens, purchased in June, 1860, and hitherto named *A. glauca*, he had come to the conclusion that the living bird belonged to the allied form *Ara leari*.—Prof. Flower called attention to the skull of the female sea-lion, which had lately died at the Southport Aquarium, and pointed out that it belonged to *Otaria gillespii*, and not, as had been supposed, to *Otaria stelleri*.—Mr. C. G. Danford exhibited and made remarks on some remarkable antlers of deer, which he had obtained during his recent journey in Asia Minor.—Prof. Newton exhibited skins of some rare species of birds obtained by Mr. Edward Newton, C.M.Z.S., in Jamaica.—Mr. F. D. Godman exhibited and made remarks on a drawing of the manatee by Mr. Wolf, taken from the specimen lately living in the Westminster Aquarium.—Hans, Graf von Berlepsch, exhibited and made remarks on the skins of two varieties of the long-tailed titmouse (*Mecistura caudata*), which occurred near Cassel, in Germany, one of which appeared to be the same as the British form of this bird.—Dr. J. Murie read a paper on the manatee, containing the results of his examination of the specimen which was lately living in the Westminster Aquarium. The peculiar attitudes assumed by the animal in life, the great mobility of the upper lip, and the occasional use of the limbs in feeding were noted. As regards the anatomy, the chief points dwelt on were the shape of the brain and its suppressed convolutions. The vexed question of the number of the cervical nerves and their distribution was also discussed.—A communication was read from Mr. A. H. Garrod, on the brain and on other points in the structure of the adult male hippopotamus, which was presented to the Society by the late Viceroy of Egypt, in 1850, and which died in the Society's gardens in March, 1878.—A second communication from Mr. Garrod contained a note on the mechanism of respiration, as well as of the retraction of the head and limbs in certain chelonia.—Dr. Gwyn Jeffreys communicated the second part of his work on the mollusca of the *Lightning* and *Porcupine* Expeditions, embracing the families from *Anomiidæ* to *Arcidæ*. The number of species noticed was 100, of which 4 were new to science, and 15 were hitherto unfigured. Particulars were given of the geographical and geological distribution of all the species, and their synonymy was discussed. Some species of *Leda* and *Malletia* were Sicilian fossils of the pliocene formation, and had not been previously known as recent or living. These species

occurred at great depths, a fact which showed that the sea-bed in that part of the Mediterranean had been considerably raised since the tertiary epoch.—Mr. Edward R. Alston read a note on the *Acanthomys leucopus* of Gray, showing that it does not belong to the genus *Acanthomys* but to *Mus* proper. As the name *leucopus* is pre-occupied in the latter genus, he proposed to call the species *Mus terræ reginæ*.—Mr. W. L. Distant read a paper on the African species of Lepidoptera of the genus *Papilio*. A new species from Magilia, East Africa, was described, and the name of *Papilio hornimani* was proposed for it. —A communication was read from the Count T. Salvadori, C.M.Z.S., containing further particulars of the new Pheasant from Western Sumatra which he had recently described as *Acomus inornatus*.—Messrs. Godman and Salvin gave an account of some hitherto unrecorded diurnal lepidoptera, obtained by the Rev. George Brown in Duke of York Island and New Ireland, together with descriptions of some apparently new species.—A communication was read from Mr. F. Jeffrey Bell, being the second of the series of his observations on the characters of *Echinoidea*. The present paper contained an account of the species of the genus *Tripneustes*.—Messrs. Sclater and Salvin read a paper on the birds of Bolivia, based principally upon an examination of the specimens obtained by Mr. Buckley during two expeditions into that country.

Geological Society, June 11.—Prof. Joseph Prestwich, F.R.S., vice-president, in the chair.—Noel W. Rudstone Read, was elected a Fellow; and M. Edouard Dupont, of Brussels, Dr. Franz von Kobell, of Munich, and Dr. Emile Sauvage, of Paris, Foreign Correspondents of the Society.—The following communications were read:—On a mammaliferous deposit at Barrington, near Cambridge, by Rev. O. Fisher, F.G.S. The gravel in which these remains were found is about 20 feet above the alluvial flat by the River Rhee, and is evidently post-glacial. The gravel contains some of the ordinary land and fresh-water shells, but not *Cyrena* or *Unio*. Remains of the following mammalia have been found:—*Ursus spelæus*, *Meles taxus*, *Hyæna spelæa*, *Felis spelæa*, *Cervus megaceros*, *elephus*, and another, *Bos primigenius*, *Bison priscus*, *Hippopotamus major*, *Rhinoceros leptorhinus*, *Elephas antiquus* and *primigenius*, with a worked flint, almost certainly from the same deposit. The author considers the abundance and admixture of these remains due to the locality having been a sort of eddy or pool in the old river. The remains are described, and the rest of the paper is occupied with a correlation of the gravel with others in the adjoining district, and a consideration of the physical conditions under which it was deposited.—Further discoveries in the Cresswell Caves, by Prof. Boyd Dawkins, F.R.S., and the Rev. J. M. Mello, F.G.S., with notes on the mammalia by the former. This paper contained the account of digging-operations carried on in one of the smaller caves of the Cresswell Crags, known as Mother Grundy's Parlour. The authors described the occurrence in the red clay and ferruginous sand of this cave of bones of hippopotamus and the leptorhine rhinoceros, proving the existence of these animals in the wooded valleys of the basin of the Upper Trent at the time of the accumulation of those deposits; while at the same time, so far as the evidence goes, there was an absence of palæolithic man, of the reindeer, and of horses, while hyænas were abundant. In a subsequent period, represented in all the caves by the red sand, the mammoth, woolly rhinoceros, horse, and reindeer inhabited the vicinity, and were subject to the attacks both of hyænas and of human hunters, whose quartzite implements prove them to belong to the same people whose traces are found in the river-deposits. In the breccia and upper cave-earth of the larger caves the existence of the palæolithic hunter is evidenced by flint implements, resembling those of Solutré, accompanied by implements of bone and antler. Associated with these was the incised figure of a horse described in a former paper. The authors finally dwelt briefly upon the characteristics of the caves in prehistoric and historic times, and indicated some of the anthropological points of interest connected therewith.—On the pre-Cambrian rocks of Shropshire, part 1, by C. Callaway, F.G.S.—On the occurrence of a remarkable, and apparently new mineral in the rocks of Inverness-shire, by William Jolly, F.R.S.E., H.M. Inspector of Schools, and J. Macdonald-Cameron, Fel. Inst. Chem., F.C.S. In this paper the authors refer to a blue mineral of a somewhat remarkable character, noticed at Englishton Moor and neighbourhood, distant westwards, from Inverness, about 5 miles, where the mineral occurs in scattered blocks. It has since been noticed at Moniack Burn, Reelig Glen, and South Clunes Farm, all in the same direction, but distant from Inverness about 10 miles; also near Dochfour House, at the north end of Loch Ness, close by Dochgarroch Lock of the Caledonian Canal. In colour and general appearance this mineral resembles crocidolite, but analyses point to its being more nearly related to ægirite, a member of the amphibole group, which has the general formula $Si3(\frac{1}{2}\ddot{\ddot{R}} + R^3)$. The mean of several analyses shows it to have the composition $6SiO_2$, Fe_2O_3, $2MgO$.

Physical Society, June 14.—Prof. W. G. Adams in the chair.—New Members: Donald Macalister, B.A., and Mr. St. George Lane Fox.—Prof. Macleod described a plan for suppressing the induction disturbances in a telephone circuit. It is known that a secondary battery composed of metal plates and sulphuric acid allows weak currents to pass while stopping those of high tension. Prof. Macleod inserted a secondary battery of platinum plate between the line and the telephone, but this stopped both the induction and the vocal currents. When platinum wires were substituted for the plates, however, the induction-currents were stopped, while the vocal currents could be feebly heard.—Dr. O. J. Lodge exhibited his new reversing key for electrometer work, which is preferred to the ordinary forms as giving a high insulation, small capacity, and not requiring the hand to approach close to it to work it. It consists of four platinum wires arranged in pairs crossing one another, one pair crossing between the other two. These are the terminals and contact pieces of the key. The middle pair are supported by an endless silk thread which runs on two pulleys, one of which is fitted with a handle. On turning the handle to right or left the two middle wires are brought into contact with one or other of the two outer wires, and the current reversed at will. The whole is inclosed in a metal box.—Mr. J. F. Moulton then demonstrated the results of the experiments of Mr. Spottiswoode and himself on the sensitiveness of electric discharges in vacuum tubes. These experiments were undertaken to find the cause of the luminous layers or strata in the discharge, a Holtz machine being employed. It was observed that when feeble currents were drawn from the machine, the discharge could be depressed by laying the finger on the tube, and this depression always occurs with intermittent currents, therefore the feeble currents form a continuous current Holtz discharge themselves, like intermittent currents, by reason of their feebleness. This sensitiveness of the discharge to the approach of the finger was found to be due to the conductivity and electric capacity of the hand. Electricity opposite in kind to the discharge is induced on the finger, and streaming upon the tube, neutralises part of the discharge therein. This effect was also shown by means of tinfoil rings round the tube. An intermittent current is of course capable of this static induction on neighbouring conductors. The luminous discharge in a vacuum-tube consists of a bright sharp glow at the negative terminal, followed by a dark space, then a hazy bluish light at the positive pole. The striæ or layers in these sensitive tubes merely repeat this appearance. They can be artificially produced by placing the fingers, or rings of metal, at intervals along a tube conveying an amorphous discharge; for in this case the induced electricity discharging itself from the fingers, breaks up the amorphous discharge into dark and bright layers. In these stratified discharges the electricity appears to travel *per saltum*, or by stepping-stones, as one may say, and the glow seems to be a molecular structure, a view which is supported by Mr. Crookes's experiments. A negative discharge from the finger produces a dark space in the tube discharge, and a positive one a bright line; therefore one can tell the kind of discharge passing in a tube by laying a finger on it. If the same pole be brought to both ends of a tube a discharge will still take place from each end, and there will be a dark space in the middle, the electricity here seeming to turn back again the way it came. The discharge from a pole through a vacuum tube would therefore appear to be not akin to conduction, but to a disruptive discharge. It is a leap in the dark, and the phenomena observed are due to the gaseous nature of the medium. These experiments point to the possibility of completing a circuit by positive electricity alone. Prof. Guthrie suggested that by combining vacuum-tubes with the conduction-balance of Prof. Hughes it might be possible to get an optical balance for measuring inductive capacity.—Dr. Henry Draper, of New York, who is now on a visit to England, then addressed the meeting on his alleged

discovery of oxygen in the sun by bright lines in the solar spectrum. He said that hitherto he had not been able to find these lines projecting from the limb of the sun, like hydrogen, and his impression is that oxygen resides lower than the reversing layer. He had lately been extending the dispersion of the spectrum of terrestrial oxygen, and from a light of maximum intensity of one-candle power had now got a dispersion of eighty inches from A to O. He exhibited two of the original negatives of the solar spectrum showing the bright lines. Mr. J. Norman Lockyer congratulated solar science on having so able a worker as Dr. Draper, and remarked that if Dr. Draper proved this case for even two or three O lines it would be sufficient, considering the variability of the spectrum of matter under different physical conditions. He also alluded to the traces of carbon which he himself had found in the sun by the dark flutings in the spectrum. Dr. Draper said he did not see why carbon should not give both bright and dark lines.—Mr. Scott exhibited a number of coloured photographs done after the method of M. Albert, of Munich.

Statistical Society, June 17.—Dr. William A. Guy, F.R.S., read a paper on tabular analysis. Dr. Guy began his paper by stating that its chief object was to call attention to a particular form of tabular analysis first proposed by Dr. Tweedy John Todd, of Brighton. Dr. Guy in the course of his paper mentioned briefly the inquiries to which he had applied Dr. Todd's method as modified by himself. He had made use of it in the inquiry entrusted to him in 1862 into the effects of the poison known as emerald-green when used in the arts; in comparing the statements made in the four gospels; in contrasting the evidence of different witnesses in the Tichborne case; in inquiries relating to poisoning by arsenic and strychnine; and in comparing poisoning by strychnine with tetanus. The general use of tabular forms for purposes of illustration was largely illustrated by various specimens which Dr. Guy had used in his lectures at King's College, and former papers read before the Society. They had reference to crime, to fluctuation in recurrent events, &c., &c. The author finished his paper by stating that he believed he did not attach undue importance to tabular analysis, or the discovery of truth by means of tabular forms, as distinct from tables of record and tables of illustration, when he anticipated from their intelligent and more extended use, not only greater accuracy of statement and completeness of description, but important discoveries also. The Statistical Society was dealing with a vast array of facts, into which scientific methods and scientific treatment are ever introducing more and more of order, more and more of light.

PARIS

Academy of Sciences, June 16.—M. Daubrée in the chair.—The following papers were read:—Transmission of the hour at Paris Observatory to commercial ports for regulation of chronometers, by M. Mouchez. He is hoping to accomplish this once a week, at least, by telegraph; but the expense is at present a difficulty.—On the development of the perturbative function where, the eccentricities being small, the mutual inclination of the orbits is considerable, by M. Tisserand.—On the spherical regulating spiral of chronometers, by M. Phillips.—Observations on M. Lamarsky's note on Stokes's law, by M. E. Becquerel. The phenomena of fluorescence do not depend on a simple change of refrangibility of luminous rays falling on a body (as M. Lamarsky seemed to say), but on a complete transformation of the vibratory movement. The illuminated body gives out, by an action proper to it, light whose composition cannot be connected in a simple way with the nature of the incident vibrations.—On the density of vapour of bisulphydrate of ammonia, by M. Sainte-Claire Deville. He gives details of this from old laboratory notes (having been reminded of the omission by MM. Engel and Moitessier).—Determination of the height of mercury in the barometer at the equator; amplitude of diurnal barometric oscillations at different stations in the Cordilleras (continued), by M. Boussingault. His observations at Bogota did not confirm Mutis's assertion of a lunar influence on the barometric heights, though a very delicate instrument was used. He found the average monthly heights greatest in June and July, least in December and January (when the earth is nearest the sun). He gives meteorological details regarding Antisana Farm, which is at an altitude of 4,100 metres.—On the last modifications made in the sluice of Aubois, and on the means used in it to deaden the percussions of the movable tubes on their seats, by preventing their rebound, by M. De Caligny.—M. Daubrée presented the first part of a work entitled "Synthetical Studies of Experimental Geology," being a collection of papers published during the last thirty years.—Observations of the planet 198, discovered at Marseilles Observatory, by M. Borrelly.—On the surface of the wave and the transformation of a pencil, by M. Mannheim.—On the employment of elliptic functions in the theory of the plane quadrilateral, by M. Darboux.—Theorems of indeterminate analysis, by M. Pepin.—Experiments on the resistance opposed by the air to movement of a surface, by M. Saint-Loup. A plate, inclined to the direction of motion, and fixed at the head of a horizontal radial bar, was driven round a vertical axis, a special arrangement being added to measure the resistance. The resistance for a plane surface of 1 square decimetre making angle ϕ with its path is expressed by the formula—

$$P_\phi = 0{\cdot}1768\,(4^{\sin\phi} - 1)\,V(11 + 1{\cdot}061\,V).$$

—On the electric dilatation of the armatures of Leyden jars, by M. Duter. He finds the law verified, which is expressed by the equation $u = \frac{KV^2}{e}$, where u is the increase of volume of the jar, e its thickness, V the difference of potential of its armatures, and K a coefficient characteristic of the apparatus. He considers that electric pressure is not the cause of the phenomenon, but that there is here a new phenomenon of electricity.—On the same subject, by M. Righi. He distinguishes *instantaneous* dilatation, due chiefly to polarisation of the glass, from *persistent* dilatation, not before observed, and due to development of heat; and he thinks it probable that at the same time the polarisation and perhaps also the attraction between the armatures produce in the glass a diminution of thickness.—On the suspension of clouds and their elevation in the atmosphere, by M. Oltramare. He offers a solution based on the idea that each molecule of a cloud is charged with electricity.—On the basic sulphydrates of ammonia, by M. Troost.—On a new natural sulphate of manganese (mallardite), and a new variety of sulphate of iron (luckite), by M. Carnot. These are from the gold and silver mines of Utah.—On the structure of cells of the kidney in the normal state, by M. Cornil. He finds them composed of two substances, the one peripheric and solidified by osmic acid, the other central, containing granulations and the nucleus of the cell.—Action of electric currents on the muscles of the claw of the crayfish, by M. Richet. Excited directly by strong induced currents, the muscle shows a very prolonged contraction, the duration of which is proportional to the intensity of the stimulus.—On the systematic position of Volvocineæ, and on the limits of the vegetable and animal kingdom, by M. Maupas. He agrees with Cohn and others in classing Volvocineæ among the algæ, with Palmellaceæ, &c.—Influence of media on the structure of roots, by M. Mez.—On a migration of butterflies of the species *Vanessa cardui*, observed at Angers on June 10 last, by M. Decharme.—On some modifications in the apparent colours of flowers by the electric light, by M. Hugo. Such changes were noticed in *Nedularium* and *Caladium*.

CONTENTS

THURSDAY, JULY 3, 1879

THOMSON AND TAIT'S NATURAL PHILOSOPHY

Treatise on Natural Philosophy. By Sir William Thomson, LL.D., D.C.L., F.R.S., Professor of Natural Philosophy in the University of Glasgow, Fellow of St. Peter's College, Cambridge, and Peter Guthrie Tait, M.A., Professor of Natural Philosophy in the University of Edinburgh, formerly Fellow of St. Peter's College, Cambridge. Vol. I. Part 1. New Edition. (Cambridge, at the University Press, 1879.)

THE year 1867 will long be remembered by natural philosophers as that of the publication of the first volume of "Thomson and Tait." They had long been waiting for the book, and in the preface the delay was accounted for by the necessity of anticipating the wants of the other three volumes, in which the remaining divisions of Natural Philosophy were to be treated. The reader was also reminded, that if in any passage he failed to appreciate the aim of the authors, the reason might be that what he was studying was in reality a prospective contrivance, the true aim of which would not become manifest until after the perusal of that part of the work for which it was designed to prepare the way.

What we have had before us now for twelve years was, the authors reminded us, strictly preliminary matter. The plan of the whole treatise could only be guessed at from the scale on which its foundations were constructed.

In these days, when so much of the science of our best men is dribbled out of them in the fragmentary and imperfectly elaborated form of the memoirs which they contribute to learned societies, and when the work of making books is relegated to professional bookmakers, who understand about as much of one subject as of another, it was something to find that even one man of known power had not shrunk from so great a work; it was more when it appeared that two men of mark were joined together in the undertaking; and when at last the plan of the work was described in the preface, and the scale on which its foundations were being laid was exhibited in the vast substructure of Preliminary Matter, the feeling with which we began to contemplate the mighty whole was one in which delight was almost overpowered by awe.

This feeling has been growing upon us during the twelve years we have been exploring the visible part of the work, marking its bulwarks and telling the rising generation what manner of a palace that must be, of which these are but the outworks and first line of defences, so that now, when we have before us the second edition of the first part of the first volume, we are impelled to risk the danger of criticising an unfinished work, and to say something about the plan of what is already before us.

The first thing which we observe in the arrangement of the work is the prominence given to kinematics, or the theory of pure motion, and the large space devoted under this heading to what has been hitherto considered part of pure geometry. The theory of the curvature of lines and surfaces, for example, has long been recognised as an important branch of geometry, but in treatises on motion it was regarded as lying as much outside of the subject as the four rules of arithmetic or the binomial theorem.

The guiding idea, however, which, though it has long exerted its influence on the best geometers, is now for the first time boldly and explicitly put forward, is that geometry itself is part of the science of motion, and that it treats, not of the relations between figures already existing in space, but of the process by which these figures are generated by the motion of a point or a line

We no longer, for example, consider the line AB simply as a white stroke on a black board, and call it indifferently AB or BA, but we conceive it as the trace of the motion of a point from A to B, and we distinguish A as the beginning and B as the end of this trace.

This method of regarding geometrical figures seems to imply that the idea of motion underlies the idea of form, and is in accordance with the psychological doctrine which asserts that at any given instant the attention is confined to a single and indivisible percept, but that as time flows on the attention passes along a continuous series of such percepts, so that the path of investigation along which the mind proceeds may be described as a continuous line without breadth. Our knowledge, therefore, of whatever kind, may be compared to that which a blind man acquires of the form of solid bodies by stroking them with the point of his stick, and then filling up in his imagination the unexplored parts of the surface according to his own notions about continuity and probability. The rapidity, however, with which we make our exploration is such that we come to think that by a single glance we can thoroughly see the whole of that surface of a body which is turned towards us, if, indeed, we are not prepared to assert that we have seen the other side too, when after all, if our attention were to leave a trace behind it, as the point of the blind man's stick might do, this trace would appear as a mere line meandering over the surface in various directions, but leaving between its convolutions unexplored areas, the sum of which is still equal to the whole surface. We are at liberty no doubt to course over the surface and to subdivide the meshes of the network of lines in which we envelope it, and to conclude that there cannot be a hole in it of more than a certain diameter, but no amount of investigation will warrant the conclusion, which, nevertheless we draw at once and without a scruple, that the surface is absolutely continuous and has no hole in it at all. Even when, in a dark night, a flash of lightning discloses instantaneously a whole landscape with trees and buildings, we discover these things not at at once, but by perusing at our leisure the picture which the sudden flash has photographed on our retina.

The reason why the phenomena of motion have been so long refused a place among the most universal and elementary subjects of instruction seems to be, that we have been relying too much on symbols and diagrams, to the neglect of the vital processes of sensation and thought.

It is no doubt much easier to represent in a diagram or a picture the instantaneous relations of things coexisting in space than to illustrate in a full and complete manner the simplest case of motion. When we have drawn our

diagram it remains on the paper, and the student may run his mind over the lines in any order which pleases him. But when we are either perceiving real motions, or thinking about them without the aid or the encumbrance of a diagram, the mind is carried along the actual course of the motion, in a manner far more easy and natural than when it is rushing indiscriminately hither and thither along the lines of a diagram.

Having pursued kinematics from its elementary principles till its intricacies begin to be appalling, we resume the study of the elements of science in the opening of the chapter on "Dynamical Laws and Principles." It is here that we first have to deal with something which claims the title of Matter, and our authors, one of whom never misses an opportunity of denouncing metaphysical reasoning, except when he has occasion to expound the peculiarities of the Unconditioned, make the following somewhat pusillanimous statement :—

"We cannot, of course, give a definition of *Matter* which will satisfy the metaphysician, but the naturalist may be content to know matter as *that which can be perceived by the senses, or as that which can be acted upon by, or can exert, force.*"

The authors proceed to throw out a hint about Force being a direct object of sense, and after telling us that the question *What is matter?* will be discussed in a future volume, in which also the Subjectivity of Force will be considered, they retire to watch the effect of the definition they have thrown into the camp of the naturalists.

Now all this seems to us very much out of place in a treatise on Dynamics. We have nothing of the kind in treatises on Geometry. We have no disquisitions as to whether it is by touch or by sight that we come to know in what way a triangle differs from a square. We have not even a caution that the diagrams of these figures in the book do not exactly correspond with their definitions. Even in kinematics, when our authors speak of the motion of points, lines, surfaces, and solids, though they introduce several modern phrases, the kind of motion they speak of is none other than that which Euclid recognises, when he treats of the generation of figures.

Why, then, should we have any change of method when we pass on from kinematics to abstract dynamics? Why should we find it more difficult to endow moving figures with mass than to endow stationary figures with motion? The bodies we deal with in abstract dynamics are just as completely known to us as the figures in Euclid. They have no properties whatever except those which we explicitly assign to them.

Again, at p. 222, the capacity of the student is called upon to accept the following statement :—

"Matter has an innate power of resisting external influences, so that every body, as far as it can, remains at rest or moves uniformly in a straight line."

Is it a fact that "matter" has any power, either innate or acquired, of resisting external influences? Does not every force which acts on a body always produce exactly that change in the motion of the body by which its value, as a force, is reckoned? Is a cup of tea to be accused of having an innate power of resisting the sweetening influence of sugar, because it persistently refuses to turn sweet unless the sugar is actually put into it?

But suppose we have got rid of this Manichæan doctrine of the innate depravity of matter, whereby it is disabled from yielding to the influence of a moving force unless that force actually spends itself upon it, what sort of facts are left us to be the subject-matter of abstract dynamics?

We are supposed to have mastered so much of kinematics as to be able to describe all possible motions of points, lines, and figures. In so far as real bodies have figures and motions, we may apply kinematics to them.

The new idea appropriate to dynamics is that the motions of bodies are not independent of each other, but that, under certain conditions, dynamical transactions take place between two bodies, whereby the motions of both bodies are affected.

Every body and every portion of a body in dynamics is credited with a certain quantitative value, called its mass. The first part of our study must therefore be the distribution of mass in bodies. In every dynamical system there is a certain point, the position of which is determined by the distribution of mass. This point was called by Boscovich the centre of mass—a better name, we think, than centre of inertia, though either of these is free from the error involved in the term centre of gravity.

In every dynamical transaction between two bodies there must be something which determines the relation between the alteration of the motions of the two bodies. In other words, there must be some function of the motions of the two bodies which remains constant during the transaction. According to the doctrine of abstract dynamics it is the motion of the centre of mass of the two bodies which is not altered on account of any dynamical transaction between the bodies. This doctrine, if true of real bodies, gives us the means of ascertaining the ratio of the mass of any body to that of the body adopted as the standard of mass, provided we can observe the changes in the motions of the two bodies arising from an encounter between them.

We then confine our attention to one of the bodies, and estimate the magnitude of the transaction between the bodies by its effect in changing the *momentum* of that body, momentum being merely a term for a quantity mathematically defined in terms of mass and motion. The rate at which this change of momentum takes place is the numerical measure of the force acting on the body, and, for all the purposes of abstract dynamics, it *is* the force acting on the body.

We have thus vindicated for figures with mass, and, therefore, for force and stress, impulse and momentum, work and energy, their places in abstract science beside form and motion.

The phenomena of real bodies are found to correspond so exactly with the necessary laws of dynamical systems, that we cannot help applying the language of dynamics to real bodies, and speaking of the masses in dynamics as if they were real bodies or portions of matter.

We must be careful, however, to remember that what we sometimes, even in abstract dynamics, call matter, is not that unknown substratum of real bodies, against which Berkeley directed his arguments, but something as perfectly intelligible as a straight line or a sphere.

Real bodies may or may not have such a substratum, just as they may or may not have sensations, or be capable

of happiness or misery, knowledge or ignorance, and the dynamical transactions between them may or may not be accompanied with the conscious effort which the word force suggests to us when we imagine one of the bodies to be our own, but so long as their motions are related to each other according to the conditions laid down in dynamics, we call them, in a perfectly intelligible sense, dynamical or material systems.

In this, the second edition, we notice a large amount of new matter, the importance of which is such that any opinion which we could form within the time at our disposal would be utterly inadequate. But there is one point of vital importance in which we observe a marked improvement, namely, in the treatment of the generalised equations of motion.

Whatever may be our opinion about the relation of mass, as defined in dynamics, to the matter which constitutes real bodies, the practical interest of the science arises from the fact that real bodies *do* behave in a manner strikingly analogous to that in which we have proved that the mass-systems of abstract dynamics *must* behave.

In cases like that of the planets, when the motions we have to account for can be actually observed, the equations of Maclaurin, which are simply a translation of Newton's laws into the Cartesian system of co-ordinates, are amply sufficient for our purpose. But when we have reason to believe that the phenomena which fall under our observation form but a very small part of what is really going on in the system, the question is not—what phenomena will result from the hypothesis that the system is of a certain specified kind? but—what is the most general specification of a material system consistent with the condition that the motions of those parts of the system which we can observe are what we find them to be?

It is to Lagrange, in the first place, that we owe the method which enables us to answer this question without asserting either more or less than all that can be legitimately deduced from the observed facts. But though this method has been in the hands of mathematicians since 1788, when the *Mécanique Analytique* was published, and though a few great mathematicians, such as Sir W. R. Hamilton, Jacobi, &c., have made important contributions to the general theory of dynamics, it is remarkable how slow natural philosophers at large have been to make use of these methods.

Now, however, we have only to open any memoir on a physical subject in order to see that these dynamical theorems have been dragged out of the sanctuary of profound mathematics in which they lay so long enshrined, and have been set to do all kinds of work, easy as well as difficult, throughout the whole range of physical science.

The credit of breaking up the monopoly of the great masters of the spell, and making all their charms familiar in our ears as household words, belongs in great measure to Thomson and Tait. The two northern wizards were the first who, without compunction or dread, uttered in their mother tongue the true and proper names of those dynamical concepts which the magicians of old were wont to invoke only by the aid of muttered symbols and inarticulate equations. And now the feeblest among us can repeat the words of power and take part in dynamical discussions which but a few years ago we should have left for our betters.

In the present edition we have for the first time an exposition of the general theory of a very potent form of incantation, called by our authors the Ignoration of Co-ordinates. We must remember that the co-ordinates of Thomson and Tait are not the mere scaffolding erected over space by Descartes, but the variables which determine the whole motion. We may picture them as so many independent driving-wheels of a machine which has as many degrees of freedom. In the cases to which the method of ignoration is applied there are certain variables of the system such that neither the kinetic nor the potential energy of the system depends on the values of these variables, though of course the kinetic energy depends on their momenta and velocities. The motion of the rest of the system cannot in any way depend on the particular values of these variables, and therefore the particular values of these variables cannot be ascertained by means of any observation of the motion of the rest of the system. We have therefore no right, from such observations, to assign to them any particular values, and the only scientific way of dealing with them is to ignore them.

But this is not all. Since these variables do not appear in the expression for the potential energy, there can be no force acting on them, and therefore their momenta are, each of them, constant, and their velocities are functions of the variables, but, since their own variables do not enter into the expressions, we may consider them as functions of the other variables, or, as they are here called, the retained co-ordinates, and of the constant momenta of the ignored co-ordinates.

From the velocities as thus expressed, together with the constant momenta, we obtain the contribution of the ignored co-ordinates to the kinetic energy of the system in terms of the retained co-ordinates and of the constant momenta of the ignored co-ordinates. This part of the kinetic energy, being independent of the velocities of the retained co-ordinates, is, as regards the retained co-ordinates, strictly *positional*,[1] and may be considered for all experimental purposes as if it were a term of the potential energy. The other part of the kinetic energy is a homogeneous quadratic function of the velocities of the retained co-ordinates. In the final equations of motion neither the ignored co-ordinates nor their velocities appear, but everything is expressed in terms of the retained co-ordinates and their velocities, the coefficients, however, being, in general, functions of the constant momenta of the ignored co-ordinates.

We may regard this investigation as a mathematical illustration of the scientific principle that in the study of any complex object, we must fix our attention on those elements of it which we are able to observe and to cause to vary, and ignore those which we can neither observe nor cause to vary.

In an ordinary belfry, each bell has one rope which comes down through a hole in the floor to the bellringers' room. But suppose that each rope, instead of acting on one bell, contributes to the motion of many pieces of machinery, and that the motion of each piece is deter-

[1] The division of forces into motional and positional is introduced at p. 370.

mined not by the motion of one rope alone, but by that of several, and suppose, further, that all this machinery is silent and utterly unknown to the men at the ropes, who can only see as far as the holes in the floor above them.

Supposing all this, what is the scientific duty of the men below. They have full command of the ropes, but of nothing else. They can give each rope any position and any velocity, and they can estimate its momentum by stopping all the ropes at once, and feeling what sort of tug each rope gives. If they take the trouble to ascertain how much work they have to do in order to drag the ropes down to a given set of positions, and to express this in terms of these positions, they have found the potential energy of the system in terms of the known co-ordinates. If they then find the tug on any one rope arising from a velocity equal to unity communicated to itself or to any other rope, they can express the kinetic energy in terms of the co-ordinates and velocities.

These data are sufficient to determine the motion of every one of the ropes when it and all the others are acted on by any given forces. This is all that the men at the ropes can ever know. If the machinery above has more degrees of freedom than there are ropes, the co-ordinates which express these degrees of freedom must be ignored. There is no help for it.

Of course, if there are co-ordinates for which there are no ropes, but which enter into the expression for the energy, then, if the motion of these co-ordinates is periodic, there will be "adynamic vibrations" communicated to the ropes, and by these the men below will know that there is something peculiar going on above them. But if they pull the ropes in proper time, they can either quiet these adynamic vibrations or strengthen them, so that in this case these co-ordinates cannot be ignored.

There are other cases, however, in which the conditions for the ignoration of co-ordinates strictly apply. For instance, if an opaque and apparently rigid body contains in a cavity within it an accurately balanced body, mounted on frictionless pivots, and previously set in rapid rotation, the co-ordinate which expresses the angular position of this body is one which we are compelled to ignore, because we have no means of ascertaining it. An unscientific person on receiving this body into his hands would immediately conclude that it was bewitched. A disciple of the northern wizards would prefer to say that the body was subject to gyrostatic domination.

Of the sections on cycloidal motions of systems, we can only here say that the investigation of the constitution of molecules by means of their vibrations, as indicated by spectroscopic observations, will be greatly assisted by a thorough study of this part of the volume.

We have not space to say anything of what to many readers must be one of the most interesting parts of the book—that on continuous calculating machines, in which pure rolling friction is taken from the class of unavoidable evils, and raised to the rank of one of the most powerful aids to science. Rolling and sliding have been more than once combined in the hope of obtaining accurate measurements, but the combination is fatal to accuracy, and these new machines, one at least of which has been actually constructed and used, are the first in which pure rolling friction has had fair play given it as a method of mechanically accurate integration.

A method is also given of combining a number of disk, globe, and cylinder integrators, so as to form a machine the motions of two pieces of which are related to each other by a differential equation of any given form. These machines all work in a purely statical manner, that is, in such a way that the kinetic energy of the system is not an essential element in the practical theory of the machine (as in the case of pendulums, &c.), but has to be taken into account only in order to estimate the magnitude of the tangential forces at the points of contact which might, if great enough, produce slipping between the surfaces. Thus, by means of a machine, which will go as slowly as may be necessary to keep pace with our powers of thought, motions may be calculated, the phases of which in nature pass before us too rapidly to be followed by us.

In the original preface some indications were given of what we were to expect in the remaining three volumes of the work. We hope that the reason why this part of the preface is omitted in the new edition is that the work will now go on so steadily that it will be unnecessary to preface performance by promise.

J. CLERK MAXWELL

ARTIFICIAL MANURES

On Artificial Manures, their Chemical Selection, and Scientific Application to Agriculture. A Series of Lectures given at the Experimental Farm at Vincennes, during 1867 and 1874–5. By M. Georges Ville. Translated and Edited by W. Crookes, F.R.S. (London: Longmans and Co., 1879.)

THOSE who take up this volume with the hope of finding the chemistry of artificial manures fully treated will be much disappointed. Not only are many of the commonest manures scarcely mentioned, but some of the most important and practical aspects of the subject are never noticed. The behaviour of manures after they come in contact with the soil is surely of the greatest importance. Chemical investigations have long ago proved that some of the ingredients of manure—as phosphoric acid and potash—are firmly held in combination by the soil, while others—as nitric acid, chlorine, and soda—are feebly retained, and readily pass away in the drainage water after rain. It has also been abundantly proved that though ammonia is firmly retained by a fertile soil, it rapidly undergoes conversion into nitric acid, which is easily washed out. The practical conclusion from these facts is plain. Diffusible manures must be applied only when the crop can make immediate use of them. Now, though M. Ville speaks voluminously concerning the application of phosphates, nitrates, and ammonium salts, no reference to the facts just indicated is to be found in his book, beyond the mere statement that clay is capable of temporarily retaining potash and ammonia.

The lectures of M. Ville are chiefly occupied by the consideration of the present state of agriculture in France, and by the recommendation of a system of artificial manuring of which he regards himself as the inventor. The condition of French agriculture is clearly, as a whole, very low; the existence of the peasant and small farmer is only maintained by the exercise of much thriftiness and self-denial. To improve this condition M. Ville very

properly recommends the consolidation of the land in large farms, and the liberal use of artificial manures.

The "normal manure" which M. Ville recommends is in its simplest form a mixture of superphosphate, saltpetre, and gypsum, thus supplying nitrogen, phosphoric acid, potash, and lime. Instead of employing the nitrate of potassium, a mixture of nitrate of sodium or sulphate of ammonium with chloride of potassium may be substituted; the manure then becomes a "normal homologous manure." This normal manure embraces all the chief elements of plant food which it may be necessary to apply to the land. It is unnecessary, however, to apply the entire mixture to every crop. Each crop demands a preponderance of one or other of the constituents of the manure; this "dominant" constituent is therefore increased when the manure is prepared for a particular crop; or the elements of the whole manure may be distributed through a rotation of crops, each crop receiving the part specially suited to it. Stated thus, we can only approve the recommendations which M. Ville has made; they are in fact, in their last-named form, precisely carried out by all our best farmers in the present day. Though, however, we have correctly stated the teaching which may be gathered from his book, there are many passages in the lectures which urge the return to the land of all the potash, phosphates, and lime which the crops have removed, a proceeding which is on many soils quite unnecessary, and therefore, very unremunerative.

M. Ville recommends that each farmer should set aside a small portion of his land to be treated with experimental manures. One plot of this ground would receive the normal manure; a second the same without nitrogen; a third the same without phosphates; a fourth the same without potash; while another plot would be left entirely without manure. By growing crops on these plots the farmer would learn in the most certain manner what elements of plant food were chiefly deficient in his soil in relation to the crops he wished to grow. This is excellent advice; no better could be given. It is only by such experiments that the true condition of the soil can be revealed; and it is only by thus testing the effect of manures before applying them on a large scale that an economic return can reasonably be expected. France is apparently ahead of us in the practical use of such experiments. Thanks to the centralisation which places the control of everything in the hands of the Government, field experiments of this description are now in progress in thirty-four farming schools throughout the country, while simpler experiments on the effects of manures have been established in connection with 350 day schools. In England we have but one place at which such experiments are thoroughly carried out, namely, Rothamsted.

Are we, then, to credit M. Ville with the discovery of the great effect to be obtained from artificial manures, or of the best mode of applying them? He claims for himself the honour of having discovered the principles he sets forth, and compares himself with Lavoisier, and his detractors with the detractors of that great man, and concludes:—"We must allow time to complete the work of justice, and give to every one his proper place." We will in reply simply mention a few dates. The famous field experiments at Rothamsted commenced in 1843; in the very first year trials were made of the effects of phosphates, potassium, magnesium, and ammonium salts. These field experiments have been carried on continuously up to the present time, and the effect of every variety of combination of manure has been shown in the fields devoted to wheat, barley, beans, clover, roots, pasture, and potatoes. That nitrogen should form the "dominant" constituent of a manure for wheat, and phosphates the dominant constituent of a manure for turnips, was clearly proved in the first two or three years of the experiments; and by 1849 the character of potash as the proper dominant in the case of beans and clover was also established. With these experiments M. Ville is well acquainted. Our last date shall be taken from his own book. The first field experiments made by M. Ville at Vincennes commenced in 1860.

The book contains several extraordinary statements. It would take too long to discuss M. Ville's views as to the assimilation of the free nitrogen of the air by all crops, but especially by the leguminosæ; immense quantities of nitrogen are, according to him, thus acquired. We are curious to know what authority he has for stating that when an animal is fed on hay one-third of the nitrogen is lost "in the act of digestion," and that another third is lost during the fermentation of the animal manure, so that only one-third of the original nitrogen is at last returned as manure to the land.

We cannot conclude without calling attention to the extremely untrustworthy character of the figures throughout the book. On p. 54 the mould on an acre of soil weighs 400,000 tons; on p. 180 it weighs 1,600 tons. On p. 353 the weight of resin yielded by an acre of pine trees is given as 4–5 cwts., but immediately after it is stated to be 1,122–1,540 lbs. The quantities of nitrogen to be applied are a complete puzzle. To take a single instance: On p. 238 we are told that to obtain a good crop of beet we must apply 70 lbs. of nitrogen per acre. On p. 357 the quantity has risen to 176 lbs. On pp. 367 and 368 the formulæ for the beet manures are given; each formula is stated to contain 187 lbs. of nitrogen; but on looking at the ingredients only 83 and 85 lbs. of nitrogen are found to be contained by the ammonium salts and nitrates employed. Finally, on p. 374 we are told that the nitrogen applied to beet should amount to 70–88 lbs. per acre. What are we to believe?

Both the old and new chemical notations are employed in the course of the book. R. W.

OUR BOOK SHELF

Lecture on the Gault. By F. G. H. Price. (Taylor and Francis, 1879.)

THIS pamphlet contains considerably more than a lecture, embodying a list of the French and English works upon the Gault, which have come under the author's notice, and nearly forty pages of tables of fossils.

The description of the gault at Folkestone has been amplified from that read by the author before the Geological Society.[1] He maintains his subdivision of the gault at Folkestone into beds, and endeavours to correlate with them, to some extent, the gault to the west. The outcrop at Eastbourne is separately described, and found to contain an unexpectedly long list of fossils. The Blackdown beds are included in the Gault, which is to be greatly regretted, for there is every reason to suppose that

[1] *Quart. Journ. Geol. Soc.*, 1874, vol. xxx. p. 342.

they are of much newer, and most probably upper greensand age: to tabulate their fauna with that of the gault, lessens the working value of the tables materially. The upper gault only is thought to be present in the Isle of Wight, where it is 100 feet thick. The little that is known of the gault in the Midland Counties is collected together, and that of Cambridgeshire and the red chalk at Hunstanton is briefly described. A few pages are devoted to the gault in France, a few lines to that of Switzerland, but no mention is made of any equivalents in Germany or in Belgium. The pamphlet contains in a compact form a deal of information upon the gault, which would have to be sought elsewhere in many publications, and it may prove of value to students at home and abroad.

The author believes that the bands which are characterised by fossils peculiar to them at Folkestone, can be traced elsewhere in England and in France. The range through the gault of most fossils is probably less restricted than is imagined, but some species are apparently strictly confined to narrow zones at Folkestone, although closely allied species abound in cretaceous rocks in England, and even America. It is likely that zones of fossils were due to the gradual alteration of depth which enabled certain gregarious forms to exist on the spot for a very short time only after their first migration to it. Their presence elsewhere would not prove that the zone was a continuous one; it would only indicate that at some period, not necessarily a synchronous one, the sea at that other spot had fulfilled the conditions of depth, &c., under which alone the particular species could exist. The same view applies to the idea that upper gault only was deposited in the Isle of Wight. There is no reason to suppose that deposition did not proceed there in the lower gault age, and it is more probable that the sea was, during the whole gault period, only fitted to receive that form of silt, and those fossils which are known at Folkestone as upper gault. The lower gault is spoken of by the author as a shallow sea deposit gradually deepening to the chalk, but the President of the Geological Society has stated his opinion that the gault is an extremely deep sea deposit, while Mr. Gwyn Jeffreys has collected much evidence to prove that the chalk was formed in shallow water. Whether we accept them or not, the views of such distinguished men should find a place in a work intended to be exhaustive.

Travels and Researches among the Lakes and Mountains of Eastern and Central Africa. From the Journals of the Late J. Frederic Elton, H.B.M. Consul at Mozambique. Edited and Completed by H. B. Cotterill. Maps and Illustrations. (London: Murray, 1879.)

ONE cannot read Consul Elton's Journals without feeling how great a loss his death has been not only to the cause of the native African, but to African exploration. Elton was only thirty-seven years of age when he succumbed to the hardships of African exploration, but he had already done more than his share of hard and useful work. The handsome and beautifully illustrated volume before us deals with his observations and adventures in Africa from 1873, when he went to Zanzibar as Vice-Consul to his death in December, 1877, when trying to push from the north end of Lake Nyassa to the coast at Dar-es-Salaam. Much of the earlier part of the volume tells of the work Elton did in putting down the slave-trade in the dominions of the Sultan of Zanzibar. In carrying out this work he had to visit most of the coast from Zanzibar to beyond Mozambique, as well as Madagascar, and with the details of his more immediate mission, is mixed up a good deal of geographical information. He carried on his works of benevolence and exploration on his appointment as Consul of Mozambique. The chief novelty of the volume, however, is in the second part, in which the story of the journey from the north end of Lake Nyassa north-east to the coast is told. Here Elton, Cotterill, and their companions broke on fresh ground, and made substantial additions to our knowledge of African geography and African people. With the main results of this journey we are already familiar, through the description of Mr. Cotterill at the Geographical Society and elsewhere. Elton left Mozambique in July, 1877, Livingstonia at the south end of Nyassa in September, and the north end on October 15. The country traversed was mainly hilly, rising in the Konde Mountains, north-west of Nyassa, to 12,000 feet. Elton speaks of the country as the "Garden of Africa." The party were delayed for a time in Merere's Country in the Konde Mountains, by one of those little wars, which so often embarrass African explorers, and during the delay some hardships had to be endured, which no doubt told on Elton's health. On December 19 he succumbed to what seemed sun-stroke, and was buried under the shade of a baobab in South Ushekke. Cotterill conducted the expedition to Bagamoyo, over what is comparatively well-known ground. In completing the narrative of the expedition and editing his late fellow-traveller's journals, in preference to publishing a narrative of his own, he has acted with an unselfishness which deserves to be acknowledged. The book is altogether one of much interest. The Rev. A. E. Eaton contributes a short Appendix on the Natural History of the Kungu Fly, out of which the natives to the north of Nyassa make cakes.

Conic Sections—The Method of Projections. By Rev. S. Bolton Kincaid, M.A. (London: Stanford, 1877.)

THIS book has only recently met our notice; it consists of a series of twenty-nine propositions deriving proofs of many of the chief properties of the ellipse by the method of circular projection. We have not come across any special novelty in the little book, nor have we detected many mistakes, though the lettering, from the use of like letters, we have found in many cases confusing. The figures face the text, and the circle figure is over the elliptical one; they are in many cases very roughly turned out by the engraver.

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts. No notice is taken of anonymous communications.*

[*The Editor urgently requests correspondents to keep their letters as short as possible. The pressure on his space is so great that it is impossible otherwise to ensure the appearance even of communications containing interesting and novel facts.*]

Comet 1879 *c* (Swift)

THE following observations may be useful to some of your readers:—On June 25 the comet was compared five times with the star O.A. 3268, with a ring micrometer (power 35); on June 28 it was compared eight times with the star Dm $+71°$, 184 by means of a bar reticule with power 70. The comet has a bright spot near the centre which, on June 25, seemed to me to be nearly equal to a ninth magnitude star; bnt on June 28 it was much fainter, although easy to observe with precision after 11h. 30m. The diameter appears to be 2′ or 3′ in my telescope (of $4\frac{1}{2}$ inches aperture) but I cannot see any trace of the tail mentioned by Mr. Swift. The comet is, however, immersed in the twilight now existing at midnight.

The Mechanical Theory of Earth-Heat

IN reference to Mr. J. P. Lesley's inquiry as to whether plicated coal-beds are generally converted into anthracite, it has occurred to me that during a residence upon the Somersetshire coal district, thirty years ago, I recollect visiting the Vobster coal-pits, on the northern edge of the Mendip hills. The coal-seams are there exceedingly disturbed. One seam of coal was

said to have been pierced three times by a vertical shaft. Yet the coals are not anthracite. The Vobster pits are very fiery. The Radstock pits, where the coal is horizontal, not so; but they are worked in higher beds.

By reference to the Commissioner's report to Parliament, 1871, it will be seen (p. 38) in Mr. Prestwich's report on the Nettlebridge Valley coals, where Vobster is situated, that my recollections are confirmed; "bituminous coal" and "disturbed condition" being alike attributed to these coal beds.

With respect to the general question of the mechanical theory of earth-heat, I would respectfully refer Mr. Lesley to my examination of the theory in the *Philosophical Magazine* for October, 1875. O. FISHER

Harlton, Cambridge

On the Origin of Certain Granitoid Rocks

IN a paper by me "On the Pre-Cambrian Rocks of Shropshire," read before the Geological Society on the 11th inst., I call attention to certain granitoid and gneissic rocks in Primrose Hill, at the south-west end of the Wrekin. Associated with these metamorphic strata in such an irregular manner as to suggest an eruptive origin is a compact felspathic rock with minute quartz grains, which I at first presumed to be a quartz felsite. On submitting specimens to Prof. Bonney, F.R.S., for microscopic examination, he declared the rock to be clastic, and closely allied to the hälleflintas, which Dr. Hicks assigns to his Arvonian group. Certain observations recently made in south-west Shropshire, suggested to me a transition between the hälleflinta and the granitoid types, and, on communicating my suspicions to Prof. Bonney, he stated that a similar connection had been suggested by his microscopic examination. This morning I hammered over Primrose Hill foot by foot, and I have the satisfaction of announcing the fullest confirmation of our suspicions. In the same block, the compact hälleflinta is frequently mixed up with granitoidite and hornblendic gneiss. In some cases, the metamorphism has taken place only near the surface, as if produced by atmospheric agencies; in others the crystallisation occurs in nests, while in others there is a gradual transition in mass from a compact to a granitic structure. This passage of hälleflinta into granite has obviously important theoretical applications.

Wellington, Salop, June 21 C. CALLAWAY

Migrations of Birds

I NOTICED some time ago a communication in NATURE respecting this subject, stating that it would be instructive and interesting alike if naturalists would record any data they may have collected on this subject. For years now this matter has had my careful attention, and I therefore forward a few notes for the last two seasons, and also put forward the hope that observers stationed in other parts of the United Kingdom will contribute information of a like nature. I would also say that the weather noted applies to the night—the time, by the way, generally chosen for migratory movements.

Vernal Migration, 1878

Dates.	Species.	Remarks.
April 4	Gray Wagtail	In pairs on the trout streams for nesting season. Weather clear, warm westerly breezes.
,, 4	Tree Pipit	In full song and seen for first time; westerly breezes.
,, 15	Redstart	In full song in Encliffe Wood and Rivelin Valley; warm westerly breezes, clear.
,, 15	Willow Warbler	Numerous, arrived during last night.
,, 15	Ring Ousel	Numerous and full of song.
,, 18	Chiffchaff	In small numbers, westerly breezes, very warm, close.
,, 19	Swallow	One specimen seen; westerly breezes, fine and clear.
,, 19	Cuckoo	Heard and saw flying over the busiest streets of Sheffield at 4.30 A.M.
,, 22	Whitethroat	One heard; dull and misty drizzling rain, W.S.W.
,, 22	Martin and Sand Martin	Numerous, in company with swallows in the Derwent Valley.
,, 28	Blackcap Warbler	First seen, but silent; warm breezes, S.E.S.
,, 29	Whinchat	Seen for first time, weather dull, S.E.S.
,, 29	Common Sandpiper	Seen for first time, in pairs, in Rivelin Valley.
May 3	Landrail	First heard, weather dull and gloomy, W.
,, 6	Spotted Flycatcher	First seen, very wet night, wind direct, S. These birds are still solitary.

Vernal Migration, 1879

Dates.	Species.	Remarks.
Feb. 10	Song Thrush	Arrived in night; dark and cloudy, wind W.
,, 10	Blackbird	Arrived in night; dark and cloudy, wind W.
March 20	Yellow Wagtail	Numerous.
,, 20	Pied Wagtail	,,
,, 29	Willow Warbler	One specimen seen, somewhat feeble, silent; wind W. by S., night dull and showery, snow only left ground day before. Never known this species so early before. Average time being April 5.
,, 29	Greenfinch	Again in usual haunts after being entirely absent during the winter, with the exception of one pair seen in a garden in Sheffield.
April 9	Chiffchaff	Saw and heard in young fir plantations at Hollow Meadows, S.W. and westerly winds.
,, 21	Curlew	In pairs at breeding grounds on moors.
,, 21	Ring Ousel	Numerous on moors, mostly in pairs; no song.
,, 24	Tree Pipit	Arrived; dull and showery weather, easterly winds.
,, 26	Willow Warblers and Chiffchaffs	On the evening of 25th not a bird was seen; on morning of 26th the birds abounded and their cheery notes are heard on every side. The night was dark and showery (new moon), wind S.
,, 26	Cuckoo	Heard in Lees-hall Wood. This bird has arrived during past night, doubtless in same flight as willow warblers, &c.
,, 28	Swallow	Seen in Meersbrook Park; weather showery and dull, wind light from S.W., moonlight.
,, 29	Whinchat	Seen in Meersbrook Park; weather showery and dull, wind light from S.E., moonlight.
May 2	Wheatear	On moors, full of song.
,, 2	Common Sandpiper	Rivelin and Redmires dams, in pairs. This species has been here some few days.
,, 2	Redstart	This bird has now arrived, but only seen in small numbers. Cold easterly winds, moonlight.
,, 5	Wryneck	Saw on Rivelin moors; solitary and uttering its whistling notes. Cold easterly winds.
,, 8	Landrail and Whitethroat	Heard in meadows; very scarce; probably came last night with a cold south-westerly breeze.
,, 12	Sand Martin	Skimming over the waters in small numbers. This species is remarkably late; wind N.W. by W.
,, 13	Blackcap	Singing in densest covers, and very shy. This species is very late. South-westerly breeze, clear night.
,, 17	Martin	Saw a pair of these birds; they are very late as compared with previous seasons. Southerly breezes and very showery.
,, 24	Swift	One seen on the borders of the Rivelin Moors. South-westerly breezes and very showery.
,, 26	Spotted Flycatcher	One specimen seen, silent and somewhat wary. N.W. by W., light, and showery moonlight night.

Such are a few extracts, taken *verbatim*, from my note-book; they might have been considerably increased, and the time of departure noted, as well as the arrival of our winter migrants, but I fear I have already trespassed too greatly on your valuable space. I sincerely trust that this interesting subject will be more fully discussed and studied by your correspondents and readers; for in that way many of the difficulties enshrouding the movements of the feathered tribes will be overcome.

Heeley, near Sheffield, June 9 CHARLES DIXON

Glow-worms *v.* Snails

YOUR correspondent, Mr. R. S. Newall, has unconsciously reversed the natural condition of affairs in his note (NATURE, vol. xx. p. 197). The heading should have been as above. Glow-worms *devour* snails, which are their natural food. The particular snail in question had probably been attacked by one of the glow-worms, which had left some of its phosphorescent matter adhering to it, and this occasioned the idea that it was showing through the body of the mollusk. Possibly in this case the snail may have proved too large for the glow-worm. An allied insect, *Drilus flavescens*, somewhat rare in this country, and not luminous, is, so far as the female is concerned, seldom

found excepting inside the shells of species of *Helix*, the animal of which it had previously devoured. R. McLachlan

Lewisham, June 27

Your correspondent, R. S. Newall, is upon the wrong tack, I think. His glow-worm was probably eating the snail, and not *vice versâ*.

In Kirby and Spence's "Entomology" I read: "Snails give sustenance to *Drilus flavescens*, a beetle, and its singular apterous female in the larva state, as well as to the larvæ of glow-worms." Is it not probable that the same food suits the imago state of the insect?

I have often found glow-worms in snail shells, and have always considered slugs and snails to be the natural food of the *Lampyris noctiluca*. R. Greenwood Penny

Bishopsteignton, Devon

Frogs and Glow-flies

Mr. Newall may be, perhaps, interested with the following extract from Darwin's "Botanic Garden," Canto iv. p. 149, note:—

"In Jamaica, in some seasons of the year, the fire-flies are seen in the evenings in great abundance. When they settle on the ground, the bull-frog greedily devours them; which seems to have given origin to a curious, though cruel method of destroying these animals; if red-hot pieces of charcoal be thrown towards them in the dusk of the evening, they leap at them, and, hastily swallowing them, are burnt to death."

I was told a few days ago of a cat which used to search for and eat glow-worms. It was suggested that she took them for *lights*. George Henslow

---

Intellect in Brutes

The following instance of sagacity in a cat has just been related to me by a friend who knew both the cat and its owner well. The latter, who lived at Ragusa Vecchia, in Dalmatia, was too poor to be able to provide food for the cat; the animal was therefore obliged to cater for himself, and was well known as a thief in the neighbourhood. One day one of the children was being sent off to school without any breakfast; the cat, hearing him sobbing for hunger, immediately went off, and returned with a piece of bread he had stolen from a baker hard by, and brought it to the child. The same thing happened another day, and he came back, dragging along a piece of meat bigger than himself. On crossing the threshold a bit of bone caught in a hole, so puss miawed till some one came to his help. This same cat, who was constantly catching birds on the roof, slept with some pet birds in a cage without attempting to touch them.

Ragusa, Austria, June 18 Margaret Evans

I send you the following instance of intelligence in dogs:— Last summer, when on a visit at the château of my son-in-law, M. Richard Waddington, Deputé, near Rouen, I had taken a walk in the grounds, accompanied by some of the family, and two favourite dogs, named respectively Minos and Rhadamanthus, followed the party, as usual, throughout the stroll. When nearing the house, on the return, my young grand-daughter remarked that Minos had lost his collar. The party came to a halt, debating whether it was worth while to go back on a searching expedition, for the pleasure grounds are somewhat extensive, and the dogs had been rambling away from the paths among long grass. Both Minos and Rhadamanthus evidently seemed to listen to the debate. It was decided to make the search at a venture, and, without saying a word to the dogs, the party commenced to retrace their steps. As a rule, these two dogs are inseparable; wherever the one goes the other goes, and invariably the two follow any members of the family when strolling about the place. At this juncture, however, Rhadamanthus, not having lost a collar, and having no special interest in the proposed search, went on her solitary way home to the stables; but Minos kept with the party, walking on the gravel path—and this for some distance—when suddenly he took to the meadow, commenced running, and presently he was observed to stop and remain fixed with his head pointed downwards, partly buried in the tall grass. Naturally he was followed. The point of his nose was in contact with the collar! Could any child of man, under similar circumstances, have displayed more *thoughtful sagacity* than did *each* of the above dogs on thé above occasion? The one thought she was not wanted, and having had enough play, wisely went home, whilst the other, thinking that his presence was requisite, wisely returned with the searching party.

When in Bute, some years ago, I heard from a gentleman, perfectly trustworthy, that a large Newfoundland dog, belonging to a friend of his, was observed one night by its owner lying concealed under his bed—a strange circumstance, because the dog was forbidden to enter the house at night. The owner, being struck by this singular occurrence, resolved not to disturb the creature, and, getting into bed, kept himself awake to watch events. It was not long before a sound was heard in the passage, a faint light was seen through the key-hole, the door opened, and instantly the dog flew from under the bed, and, springing forward, brought a man to the ground, the gentleman's own servant, who, accompanied by another fellow, was there for the purpose of robbery. Chas. Popham Miles

Vicarage, Monkwearmouth

Having read Mr. Peach's letter on "Intellect in Brutes," as shown by the sagacity he witnessed in his dog, I have been asked to send a similar anecdote, which I have often told to friends. Many years ago my husband had his portrait taken by T. Phillips, sen., R.A., and subsequently went to India, leaving the portrait in London to be finished and framed. When it was sent home about two years after it was taken, it was placed on the floor against the sofa, preparatory to being hung on the wall. We had then a very handsome large black and tan setter, which was a great pet in the house. As soon as the dog came into the room he recognised his master, though he had not seen him for two years, and went up to the picture and licked the face. When this anecdote was told to Phillips, he said it was the highest compliment that had ever been paid to him. X.

Some years ago a fine arts exhibition was held at Derby. A portrait of a Derby artist, Wright, was thus signalised: "The artist's pet dog distinguished this, from a lot of pictures upon the floor of the studio, by licking the face of the portrait."

Derby Henry Clark

Butterfly Swarms

With reference to the swarms of butterflies referred to by M. Forel, in Nature, vol. xx. p. 197, it may be interesting to mention that *Vanessa cardui* is this year very common in the south of England. This butterfly is known to all English lepidopterists to be "periodical"—in some seasons it occurs in great numbers, in others—perhaps for several years in succession—not one specimen is to be seen.

Last season (1878) I saw no specimens, nor did I hear of any about here. It seems, therefore—in such a bad season for insects as the present—impossible to consider the abundance of the species in England to be the result of "local fecundity." Whence, therefore, come these specimens? and is the periodical abundance of the species in Britain due to local causes or migration? J. H. A. Jenner

4, East Street, Lewes, July 1

THE KILBURN SHOW

It is difficult to estimate the disadvantages with which the Agricultural Exhibition at Kilburn has had to contend. So large a show must always be somewhat unwieldy, however skilfully planned, but the melancholy wet season has enormously increased the difficulties of arrangement, and we may add that fairly to study the implements and miscellaneous exhibits was quite impossible up to the time of our going to press. A few jottings set down at random concerning such instruments, operations, and specimens as drew our attention while in the yard on Monday must suffice on the present occasion. Visitors were supposed to view the exhibits from the avenues between the long rows of sheds; but these avenues, once grass, were transformed into roads of mud, in every condition of matter between the solid and liquid states. There were no paths across the sheds, and as most of the implements and other exhibits were not so arranged as to be approachable on more than one side, the difficulty of examining objects of interest was frequently insurmountable.

Perhaps the comparative loan collection of farm implements is the most noticeable feature of the whole show. The paucity of labels and the filthy condition of the ground notwithstanding, the rollers, ploughs, harrows, drills, threshing, winnowing, and reaping machines, are full of interest. Of the actual specimens shown, but few, if any, date back further than the last century, while the majority belong to the first half of the present. The reapers, including Bell's reaper of 1826, form an instructive series.

When, about the year 1850, steam was becoming more generally used for agricultural operations, an immense impetus was given to the improvement of farm machinery. Richard Trevithick's portable engine, made at Hayle Foundry, in 1811, and put upon Sir C. Hawkins's farm at Trevithen for working a threshing machine, is an historical agricultural relic far too curious to be allowed to return, after the Kilburn Show is closed, to its prosaic duties in Cornwall. It should be secured for the Patent Museum at South Kensington. It must be regarded as inaugurating the practical use of steam on the farm. The later steps in the progress of steam cultivation may be studied in this loan collection and in the modern implement sheds with tolerable completeness.

Before leaving the subject of the loans exhibited at Kilburn, we may direct our readers to a case exhibited by the Secretary of State for India. It is to be found close to the house in which the plans for farm-buildings are arranged, and in a line with one of the historical [implement sheds. The case in question contains specimens of wheat from our Indian Empire, and is accompanied by a map, some remarks on the quality of the wheats, and some statistics. From the latter we learn that India produces 40 million quarters of wheat, of which but 1·3 millions were exported in 1877; that the demand for wheat of the whole world is at the most but 25 million quarters; and that the United Kingdom requires an average import of 11 million quarters, in addition to her home production of the same quantity. Had chemical analyses of some of these samples of Indian wheat, together with their mill-products, been added to this exhibit, it would have been still more instructive.

In the same shed with the Indian wheats there are shown a series of seventeen cases illustrative of the composition and nutrition of the human body. These are lent by the South Kensington Museum and from what is known as the "Circulating Food Collection." It constitutes a small replica of the most characteristic parts of the Food Collection at Bethnal Green, and like the latter, has been arranged and fully described by Prof. Church. It supplies in an exact yet popular form an immense amount of information concerning the elements and compounds of the human body and of food; and concerning the amount and nature of a day's ration, the equivalents of foods, the analysis and adulteration of alimentary products, the qualities and testing of waters. It has been lent to several provincial exhibitions already, and forms an admirable instrument of popular instruction.

Turning to another department of the show we notice, amongst the raw materials used in the manufacture of manure, some specimens of native phosphates which claim our attention. The search for anything that can be made into superphosphate has certainly been most exhausting. As one supply fails a new one is discovered. The Canadian apatites shown at Kilburn are very fine. Some hexagonal prisms and pure blue crystalline masses are quite museum specimens. Some samples of what are called Russian coprolites are exhibited on Stand 615. They are large and have a well-marked radiate structure, closely resembling that often seen in iron pyrites.

We do not recollect ever having before seen the seed of the locust bean, *Ceratonia siliqua*, prepared for food by simple splitting, as shown in a fine sample (No. 11,081) on Stand 595. Some specimens of selected or pedigree wheat, on Stand 629, are noticeable.

The artificial drying of hay and some other crops is likely to be more extensively employed before long. Mr. W. A. Gibbs, the inventor, shows some improved forms of his implement for this purpose. They effectually get rid of the excess of moisture in the materials submitted to the process of artificial desiccation without stewing them. One machine can dry out 35 per cent. of water from hay at the rate of twenty loads a day. Another instrument, of which a model is also shown, is specially adapted for drying tea, coffee, manures, hops, and fruit.

It is impossible to do justice, in a single set of brief jottings like the present, to any of the subjects we have handled. We can but direct attention to some of the characteristic features of the stands, and to two or three out of the thousands of specimens shown. We should like to have dwelt upon numbers of inventions to which we have no space to allude; but we cannot refrain from noticing the exquisitely ingenious application of hydraulic pressure to the automatic opening, and, what is more curious, the automatic closing, of entrance gates by the pressure of the passing vehicle. The interval between the opening and the spontaneous closing of these gates can moreover be regulated to a nicety by a previous adjustment. A large working model of this invention will be found at Stand 141, the patentee being W. Walton, of Runiley, Manchester. We must also note a charming chromolithographic diagram of the colours acquired by the metal in tempering steel from the pale straw proper to "scrapers for brass" through shades of orange, red, and purple to the deep blue of "springs." This was issued as a supplement to the *Ironmonger* of April 5, 1879, and is shown at Kilburn on the stand appropriated to that paper.

We have not space to speak of the many admirable features of the showyard, nor even of the delightful little train of steam tramcars working on rails of less than two feet gauge. But we may return to the subject of the Kilburn Show next week.

MAJOR PINTO'S AFRICAN JOURNEY

MAJOR SERPA PINTO has been lecturing in Lisbon to a distinguished audience on his journey across Africa from Benguella to Durban. He apologises for the disjointed character of his lecture, for which he had no time to prepare, and which, therefore, cannot be taken as anything like a complete account of the results of his journey. There is some likelihood of his soon being in London, and probably then he may give us a more systematic account of what he has been able to gather in the interesting region through which he passed. A good deal has been said of the large natural history and other collections he has made, and if these be such as they have been represented, science will certainly be much indebted to the gallant Major, who has tried to revive the glories of the old days when Portugal was in the front rank of exploring nations. A good many difficulties were met with at the beginning as usual, and Major Pinto deemed it advisable to separate himself from his companions Ivens and Capello, who took a more northern route, and as they had various scientific instruments with them, including such as were suitable for observations in terrestrial magnetism, possibly they may have some important contributions to make to science.

It is difficult to make much out of Major Pinto's rambling talk, which often reminds us of the vague and wonderful stories told by the simple travellers of old. He certainly seems to have made important rectifications in the hydrography of South-West Africa, especially of that flat table-land about 12° S. and 18° E., where within a few paces one can drink of the water of the sources of the Zambesi, Coanza, and Cubango, and where it can easily

be conceived that in wet seasons the oozing waters will have some difficulty in making up their minds whether to take their course to the Atlantic, the Indian Ocean, or by the Cubango south to the sands of the Kalahari Desert. Major Pinto's real starting-point was Bihé, the eastern limit of Portuguese West Africa. Going south and east by the Kalahari Desert, through the Transvaal, he came upon the scene of the Anglo-Zulu strife, and was safely carted to Durban. He suffered the usual hardships of desertion by followers, starvation, fighting hostile tribes, and narrow escapes from cataracts. To the west of Bihé he discovered the source of the Cubango, which, he states, loses itself in the Kalahari Desert, after overflowing to form Lakes Ngami and Macaricari, the latter of which is sometimes dried up. There is no connection, he says, between the Cubango and Cuando, the latter, after receiving many feeders, finding its way to the Zambesi, where, at its mouth Livingstone gave it the name of Chobé. A good deal of his information Pinto seems to have derived from a map drawn by a Bihé native. The river Cuqueima, he tells us, is an affluent of the Coanza, west of the Cubango. At its source the Cuando is a little rill, but soon becomes navigable, many of its tributaries being navigable also. Going through Ungo-é-Ungo, between the Cuango and Upper Zambesi, he found the ground all miry, an immense marsh; "water covered everything." From the Bihean's map he found that the most southern source of the Lualaba lies between those of the Liambai, or Zambesi, and the Luengué, and in 12° S. lat., "like those of the other rivers of Africa." The Luengué, or Cafuque, the "Cafue" of Livingstone, a tributary of the left bank of the Zambesi, the Major states, has not a single cataract, and should form the real key to Central Africa. The river that connects Lakes Bangweolo and Moero, he states, is not the Lualaba, but the Luapula; did not Livingstone say so? Lualaba, Pinto says, is the name given to the west arm, which extends to 12° south, and must be considered the real source of the Congo, and not the Chambeze, which enters the east end of Lake Bangweolo. On a recent map of Africa, we find the Lualaba placed as described, and as to which is the source of the Congo, it is a matter of opinion as to what "source" means.

The Zambesi seems to be more notorious for cataracts than even the Lualaba—Congo; Pinto and his men descended thirty-seven; he saw thirty in the space of an hour and a half "that had never been mentioned by any one."

At the junction of the Cuando and Zambesi, Major Pinto found an English naturalist from the Cape, Dr. Bradshaw, "who was reduced to the greatest misery," wandering about barefoot, and carrying in his hands a pair of shoes, with only a tattered shirt and a pair of trousers on. Dr. Bradshaw's extreme misery he seems to have borne with equanimity; he gravely presented his carte-de-visite, taken in London, to his Portuguese fellow-explorer. He was shooting birds and collecting animals for "the English museums." Near the same place a French missionary family befriended the sorely beset traveller, and helped him out of his difficulties. At the beginning of his journey, at Caconda, he met another naturalist, a Portuguese, Anchietta, who has been twelve years in Africa, and "has enriched one of the best African museums in the world, that of the Lisbon Polytechnic School, which is under the direction of Dr. Bocage." Have the treasures of this African Museum ever been described? Anchietta was more fortunate than the miserable English naturalist, who received the major in his drawers. The Portuguese, on the contrary, received his compatriot "in the woods, wearing a white necktie and a dress coat, and offered us tea in cups of porcelain of Sèvres." Still Anchietta, with all his attention in the wilds of Africa to the usages of ceremonious Europe, seems to be a hard-working naturalist.

The only other point in Major Pinto's lecture we need notice is his observation as to a race of white Africans, which will recall to the reader what Stanley says about the white inhabitants of the lofty mountain near the Albert Nyanza. We shall let the Major tell what he observed for himself:—

"I one day noticed that one of the carriers was a white man. He belonged to a race entirely unknown up to the present day. A great white people exists in South Africa. Their name is Cassequer; they are whiter than the Caucasians, and in place of hair have their heads covered with small tufts of very short wool. Their cheek-bones are prominent, their eyes like those of the Chinese. The men are extremely robust. When they discharge an arrow at an elephant the shaft is completely buried in the animal's body. They live on roots and the chase, and it is only when these supplies fail them that they hold any relations with the neighbouring races, the Ambuelas, from whom they obtain food in exchange for ivory. The Cassequeres are an entirely nomadic race, and never sleep two nights in the same encampment. They are the only people in Africa that do not cook their food in pots. They wander about, in groups of from four to six families, over all the territory lying between the Cuchi and the Cubango. It would seem that from a crossing of the Cassequeres with the negroes of other races, sprang those mulattoes of the South whom the English call bushmen. The latter are, however, better off than the Cassequeres, and use pots in cooking their food, while their dispositions are good, though quite opposed to civilisation."

We cannot doubt the accuracy of the Major's observations, though we should require to know more of the curious people he speaks of before pronouncing on their origin and affinities.

Altogether it will be seen that Major Pinto, while hardly having a claim to be ranked among "the foremost of explorers," has done a piece of good and useful work amid a good many dangers, work creditable to himself and his country, which, we trust, will be stimulated by his example to do what she ought for the complete exploration of that part of Africa which forms, so to speak, the back garden of her West Coast colonies.

THE COMPARATIVE ANATOMY OF MAN[1]

I.

HUMAN anatomy, as ordinarily taught, has for its end simply the knowledge of the structure of the body of the man we have most to deal with in our practice, that is, the European man, in his usual average development. No cognisance is taken of the deviations from this ordinary but known type, except as individual variations, which have their principal interest in any interference they may cause with our diagnosis or treatment of the diseases or injuries to which our frame is liable.

The comparative anatomy of man goes beyond this. Instead of aiming at describing a general average man, by overlooking, or purposely eliminating, all deviations from the normal standard, it is specially occupied in studying the differences between one man and another, estimating and classifying these differences, and especially discriminating between such differences as are only individual variations (variations which, when extreme, are relegated to the department of the teratologist) and those that are inherited, and so become characters of distinct groups and races of the human species. Physical anthropology, moreover, extends its range beyond merely comparing and registering these differences of structure. It also occupies itself with endeavouring to trace their cause, and the circumstances which may occasion their modifications. It endeavours, also, to form a classification of the different groups of mankind, and so to throw

[1] Abstract of Prof. Flower's Hunterian Lectures, delivered at the Royal College of Surgeons, commencing on Wednesday, March 5.

light upon the history and development of the species. These are all exceedingly difficult and complicated problems.

As an example of one of the problems which the student of the Comparative Anatomy of Man sets himself, may be quoted the relation of the size of the brain to that of the rest of the body in different races and different individuals. An important contribution to this much-vexed question appeared in the last number of the French *Revue d'Anthropologie*, by M. Gustave Le Bon, in which the author, among other things, endeavoured to show that in lower races, and uncivilised conditions of the higher races, the brains of men and women were comparatively equal in size and weight, but that with elevation in the scale and advance of culture, the differences between the sexes increased, the women's brain remaining stationary, while that of the men augmented. There are, however, some fallacies in the statistics quoted in support of this proposition, which might apply to the women of France, although not to so great a degree as M. Le Bon seems to imply. The lecturer showed that in England, according to the best information yet obtained, the proportional size of the female brain to the male was as 9 to 10, very nearly the same as in the lowest and least cultivated of the races quoted by M. Le Bon.

As regards the relative size of the head in men, it seems probable from the investigations of Mr. Francis Galton and others, that on the whole men with the greatest amount of intellectual capacity have large heads, although this is by no means always the case. Small heads are frequently accompanied by great energy.

The Australians were described in last year's lectures, but as they are a very interesting race, being both socially and physically the most different from ourselves, it may be as well to go over some of their principal characters again.

Their habits are very primitive, their only domestic animal being the native dog, and their only weapons the boomerang, spear, and lance, having no bows and arrows. They have not acquired the art of pottery making. One of their principal characteristics is the small size of the brain-cavity compared with that of a European, the largest not coming up to the size of the average Italian peasant. Since last year five Australian skulls have been added to the museum, which are all extremely characteristic of the race. The average capacity of these five is 1,234 c.c., while the average of five ordinary European skulls is 1,574 c.c.

Another characteristic of the skull is that it is long and narrow; the cephalic index, or relation of the greatest breadth in the parietal region to the extreme length, which is taken as 100, being on the average 71 or 72. The super-orbital ridges are extremely pronounced, and the orbits are elongated, and short from above downwards. The nose is short and wide below, and the jaws project forwards. The skin of these people is dark, and their hair is black, but not curly.

The Tasmanians are in some respects allied to the Australians, and in others differ greatly from them.

Tasmania was discovered in 1642 by Abel Tasman, but it was not until 1777, when Capt. Cook visited it, that the intercourse between the English and the Tasmanians commenced. In 1803 it became an English colony. The race is now entirely extinct, the last man having died in 1869, and the last woman in 1876.

Unfortunately, but few skulls have been preserved, and we have very little information about this curious and interesting race. Their habits seem to have been very primitive; they had no domestic animals, not even the native dog, and no boomerang, their only weapons being a lance and a club or "waddy."

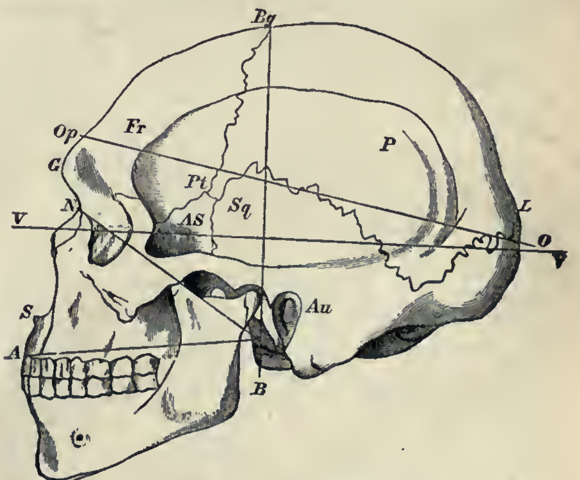
The skull is very characteristic, the parietal part being broader than in that of the Australians, and the hair is woolly, something like that of a negro, a microscopic section showing it to be flattened and elliptical, while straight hair is more or less cylindrical. They have probably been isolated from all other races for a great length of time, though it is likely that Australia was once inhabited by a people resembling them.

The islands of the Pacific Ocean proper are inhabited by two extremely distinct and different races, which are, however, often much intermixed. One of these, the Papuans or Melanesians, are very like negroes, having woolly hair, broad noses and mouths, and low orbits; the skull is long and narrow, and more like the Australian type. The other—the true Polynesian—of which the Samoans and Tongans may be taken as the best types, have more or less straight hair, and in many respects resemble the Malays; their heads are round, and they have a fine high face, with a long and narrow nose and a round short mouth. These latter are much more highly civilised than any of the races described above; when they were discovered, at the end of last century, they had houses, clothes, domestic animals, canoes, &c.

It seems very probable that these islands were once inhabited much more extensively by Melanesians, the Polynesians having colonised those which extend from the Sandwich Islands, on the north, to New Zealand, on the south, and having in most cases replaced the original race. Mixtures have also taken place, as in the Maories of New Zealand.

A few details must now be given about the methods of measuring the capacity of crania. This is a much more difficult operation than might at first sight be supposed. The best method seems to be that used by Mr. Busk, viz., filling the skull with rape or mustard seed, which is then measured with an instrument called a choremometer. It should always be filled to a maximum, a funnel of a certain aperture being used, and the seed being well shaken and pressed in, as a difference of three or four cubic inches may be made if these precautions are not attended to.

The capacity of a skull, as well as its extreme dimensions, varies much in proportion as it is wet or dry. One which measured 520 linear millimetres in circumference in summer increased 7 millimetres in winter.



Side view of skull of male Australian. *VV*, horizontal line, corresponding with visual axis; *A*, alveolar point; *S*, spinal point, or base of nasal spine; *N*, nasion, or centre of fronto-nasal suture; *G*, glabella; *Op*, ophryon, or centre of super-orbital line; *Bg*, bregma, or union of coronal and sagittal sutures: *L*, lambda, or union of lambdoid and sagittal sutures; *O*, occipital point; *Au*, auricular point, or centre of external auditory meatus; *B*, basion, or centre of anterior margin of foramen magnum; *Pt*, ptereon, or point where the frontal (*Fr*), parietal (*P*), squamosal (*Sq*), and alisphenoid (*AS*) bones meet.

The circumference of a skull is taken by passing a tape round it from a point called by Broca the *ophryon*, which

is the centre of a line taken just above the supra-orbital ridge or glabella, to the *occipital point*, or most prominent point of the occiput. The division commonly made between the anterior and posterior parts of the skull is by a line drawn from the middle of the external auditory meatus, or *auricular point*, to the *bregma*, or point where the coronal and sagittal sutures meet. The skull of a gorilla differs greatly from that of a European in the diminution of the portion situated behind this line, and the Australian cranium approaches the former where it differs from the latter, the posterior half being smaller than in the European.

The facial angle, or angle made by the profile with a horizontal line, is obtained by placing the skull in such a position that the axis of vision is horizontal. This is done by passing a rod exactly through the centre of the anterior opening of the orbit, and through the optic foramen. By means of a square, the amount of projection in front of or behind any given point can then be ascertained.

The three points forming what is known as the facial triangle are the *basion*, or centre of the anterior margin of the foramen magnum, the *nasion*, or centre of the fronto-nasal suture, and the *alveolar point*, or middle point of the upper jaw. The length is usually taken from the ophryon, but some take it from the glabella. The breadth is the greatest breadth in the parietal region.

Narrow skulls are called *dolichocephalic*, and broad ones *brachycephalic*. Taking the length as 100, if the index of breadth is above 80 the skull is brachycephalic; if below 75, dolichocephalic; while if it lies between these numbers it is called *mesocephalic*.

The height is taken from the basion to the bregma.

The form of the orbit varies much. The orbital index, or relation of the length (taken as 100) to the breadth, is very low in the Australians, the average being about 80. The form of the nose is characteristic both in races and individuals; the width compared with the height gives the nasal index. This varies much in individuals, but general averages are very important. The average nasal index of Australians is 57. Broca calls those races whose nasal index is lower than 48, *leptorhine;* between this and 53, *mesorhine;* and above 53, *platyrhine*.

The name *metopic* has been given by Broca to those skulls in which the suture between the frontals remains open in the adult. It generally closes up at the end of a year or two, and if it does not unite then, it rarely does afterwards. In European races this metopism is seen in about one cranium in ten, while in Australians and other low races it is extremely rare, as in monkeys.

The different races of men have been classified into two great groups according to the character of the hair, viz., the *Ulotrichi*, or woolly-haired people, and the *Leiotrichi*, or smooth-haired people. Mr. Charles Stewart has shown that, besides the difference in the microscopical structure of woolly and straight hair already mentioned, there is a difference in their mode of growth. The follicle in which an ordinary hair is developed is straight, while in the case of woolly hair it is curved, thus giving the hair a spiral twist. The woolly-haired people inhabit the greater part of Africa, and also a chain of islands extending from Tasmania to New Guinea and the Andaman Islands. These latter, or oceanic negroes, differ considerably from the former, or African negroes, and also differ very much among themselves. They may be divided into two distinct branches, an eastern and a western, and it is very difficult to determine whether they all arose from the same stock. In the eastern branch the people are nearly all characterised by high, narrow heads, much compressed at the sides, and features resembling the Australians.

The Museum of the College of Surgeons has lately received an interesting addition to the collection, viz., a dried man, painted red and otherwise ornamented, and fixed on a sort of hurdle, which was found in a hut on Darnley Island, in Torres Strait. The head of this man is less dolichocephalic than that of most Papuans, but it had probably been artificially compressed in infancy, many of these people having this peculiar custom. The mouth is large and projecting, but the nose is better formed than in the Australians.

When the Spaniards took the Philippine Islands they found them chiefly inhabited by Malays, but also in the wilder parts by a small race which they named Negritos. These have black complexions, woolly hair, and negro-like features. They perhaps extend as far north as to the south of Japan, but they are best marked in the Andaman Islands, where the race retains its purity.

The Andaman Islands consist of a long narrow chain of four principal islands, the Great Andamans, separated by narrow channels, as well as some smaller ones, called the Little Andamans. The first reliable notice of these islands is by some old Arab voyagers in the 9th century. No European traveller visited them until the end of last century. In 1788 a convict station was established at the south end, at a place which was called Cornwallis. This was soon abandoned, and another settlement made on the north. This, again, however, was given up, and it was not until November, 1857, that the Government once more took up the question and established a settlement on the site of Cornwallis, which is now called Fort Blair. For four or five years the natives were very shy, and the accounts of them are very unsatisfactory. They are now, however, becoming civilised, the English governors having built houses for them, and allowing them a certain quantity of food.

Although this chain of islands is only about 140 miles long, there are as many as nine distinct tribes speaking different languages. During the last year Mr. Man has sent over a valuable collection of their manufactures, and these show that in some respects they occupy a higher grade of civilisation than the Australians, Tasmanians, &c.

In the Little Andamans the people built beehive-like houses, but in the Great Andamans they had no permanent houses or clothes, the substitute for the latter being a thick coat of mud and pig's grease. A good deal of taste is shown in the manner in which this clothing is ornamented, one man being seen with half the body red and the other half yellowish, and ornamented by zigzag lines. A favourite ornament is a necklace made of the finger-bones of deceased relatives.

The Polynesians have a very general custom of preserving the bodies both of friends and enemies; the Borneans preserve their enemies, but the Andamanese give the preference to their friends. A widow often wears her husband's skull round her neck as an ornament.

The Andamanese do not cultivate the ground, but they are very expert with the bow and arrow. They cook their food, which consists principally of wild pigs and fish. They make canoes, hollowed out of the trunks of trees, and also a rough kind of pottery, simply moulded by the hand. There is no proof that they ever practised cannibalism, notwithstanding the frequency with which the charge has been brought against them.

There is much difference in the descriptions of travellers of the features and general characters of these people; some say that they are all very much alike, and others that they vary considerably both in form and features and character of hair, which is usually extremely black, close, and woolly. A section shows it to be nearly as flat as that of a South African Bushman. They, however, generally keep their heads shaved. All photographs hitherto sent to Europe show a very close general resemblance. The head is round, the forehead broad and upright, the nose small and straight, and the lips not very thick or projecting. They are a very small race, the average height being under five feet, the women being

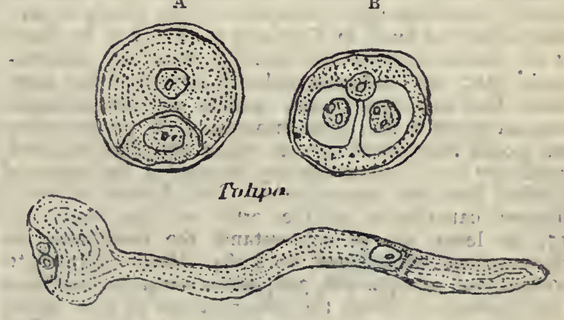
shorter than the men. There are, in fact, only three other races which are equal or approximate to them in smallness, viz., the Bushmen, the inhabitants of Tierra del Fuego, and the Lapps. The name of *Mincopie* has often been applied to these people, but it does not appear to be now used in the islands.

(*To be continued.*)

ON POLLEN PLANTS

THE evolution of the vegetable cell—using the word evolution as defined by Herbert Spencer—is a subject of immense interest that is now engaging the attention of some of the most scientific of the botanists. While the important researches of Carl Nägeli on cell-structure and cell-development can never be over-estimated, yet in these more recent times we are greatly indebted to the original and remarkable researches of Eduard Strasburger, which have thrown a flood of light on the subject, and opened out for it new and as yet untrodden by-paths. His thoughtful work, "Ueber Befruchtung und Zelltheilung," ought to be in the hands of every student. It is not here purposed to analyse the contents of this volume, now more than eighteen months on our shelves, but in it, we fear somewhat overlooked, we find the subject of the cellular-structure of the "pollen grains" in the angiosperms first mentioned, at least, in very recent times, and we are glad to perceive that the facts relating thereto have been recently restudied, and in some detail, by Fredr. Elfving, of Helsingfors, under the eye of Strasburger, and in his physiological laboratory at Jena.

We adopt for convenience the ordinarily received division of plants, in which the flowering plants, or those having the sex-cells developed in connection with phyllomes, are separated from the so-called flowerless plants, in which the sex-cells are formed on thallomes. All the more recent manuals of botany assert that the two groups of the former, the gymnosperms and the angiosperms, are differentiated, the one from the other, by certain striking peculiarities relating to their reproductive systems. One of these is that in the former the pollen-grains are multicellular, and that in the latter the pollen-grains are unicellular, a nice, and it ought to be an easily ascertained distinction, but unfortunately one that turns out on investigation not at all true. In the pollen-grains, or, as we would prefer to call them, the pollen-plants of the gymnosperms, there are all the essentials of an adult and independent form, that is to say, the protoplasmic contents of the pollen plant divide into two or more cells, of which one takes upon itself the growth and functions of the pollen tube, and the other remains with no such functional power, but at most plays the feebler part of a vegetative cell. There is thus, as it were, a thallus formed, one cell of which performs the function of an antheroidal or male cell. All this has been for some time known to be the case in the gymnosperms of which our cone-bearing trees and shrubs may serve as familiar types; but in the angiosperms, embracing nearly all our showy flowering herbs, shrubs, and trees, despite Strasburger's researches published in 1877, it is still most generally stated that inside the inner coat of the pollen-grain there is but a single protoplasmic mass which gives rise to the pollen tube. So far as this difference in the pollen goes, it will now probably not be again insisted on, for a glance at the very copious figures drawn from nature by Mr. Elfving will satisfy the most sceptical that the angiospermous pollen-grain is really a compound body, entitled to rank as a thallus, and in which, as in the gymnosperms, there are both functional and vegetative cells. The researches culminating in this memoir were chiefly made during the summer session of 1878 in the Botanical Institute at Jena. The pollen was cleared by means of a 1 per cent. solution of osmic acid, and then stained and preserved in a carmine-glycerine fluid. If the outer coat be not too dense, the contents can be seen through it after from one to two days' steeping in osmic acid. In order to see the growth of the pollen tube, recourse must be had to artificial culture; for this purpose many sorts of solutions were used, and these of very different degrees of condensation, but in the end the author came back to a simple solution of 1 to 25 per cent. of sugar. Some pollen plants required but weak solutions, others strong ones. The strength of the solution found in certain cases most useful is given in the details of the experiments. The culture upon most were generally made in the dark, and at a summer temperature, but some grown in daylight succeeded admirably. The orchids are referred to as affording most excellent subjects for these investigations. On three plates the different forms of pollen-plants to be met with in some twenty-three species of plants are represented. Of these we select that of *Tulipa gesneriana*, in which the vegetative cell happens to be very large (A in figure), and it very frequently divides, as seen at B, also that from *Butomus umbellatus* (C), showing the vegetative cell and the tube. In this figure the side walls are not represented. The chief results of these researches are collected together as follows:—The pollen-grain in the angiosperms becomes divided into two cells, generally a larger and a smaller one; the latter, the "vegetative" cell, by a further division, becomes developed into a two- or often a three-celled thallome. This vegetative cell, or these vegetative cells, are only separated from the larger cell by a wall of cortical plasm, (ectoplasm, Vines), but this, in particular instances, can become formed into a firmer membrane (cellulose?). The pollen tube is the result of an outgrowth of the larger cell.



In the gradual growth of this it may happen that the vegetative cell or cells will wander into the pollen tube, the wall of the larger cell having become obliterated, or they will remain free in the cavity of the mother-cell, often becoming spindle or half-moon-shaped.

The nuclei are often peculiarly fashioned, but with the exception of the Cyperaceæ no instance of a division of the nucleus of the larger cell was observed.

All the pollen plants described by Elfving belong to the sections either of the "wind-wafted" or the "insect-borne" forms. The study of the structure of the pollen plants of such cleistogamous flowers as those recently described by Bennett, such as some of the violets, wood sorrel, &c., may reveal some interesting facts. In them there would seem to be a greater individuality; the very behaviour of their pollen tubes is so different that they would appear as if they had a more independent basis; but this is rather a subject for research than for conjecture. In the meanwhile we may note how many apparently sure landmarks have been, in the botanist's country, lately thrown down by the researches of Warming, Strasburger, and now Elfving. It will be difficult by and by to invent neatly-

worded definitions to separate the sub-kingdoms, classes, and sub-classes of the vegetable kingdom. Modern research is now all destructive, nor seems it to have a thought as yet of proceeding on the lines of scientific construction.

E. PERCEVAL WRIGHT

OUR ASTRONOMICAL COLUMN

OLBERS' COMET OF 1815.—The Royal Society of Sciences of Haarlem have offered a prize for a new determination of the elements of this comet, founded upon the whole series of observations which remain in a form admitting of more accurate reduction than they have yet received, by the use of improved positions of the comparison stars and a calculation of the effect of perturbations, while the comet was visible, with the more precise values of the planetary masses which we now possess. Bessel, in his final memoir upon this comet, not only investigated the elements of the orbit from the *ensemble* of the observations in the form in which they were known to him in 1815, but essayed to determine the effect of planetary attraction upon the epoch of next return to perihelion, which he fixed to February 9, 1887, but he found that the period of revolution resulting from the observations in 1815, was liable to a probable error of ± 101 days. Unless the semi-axis major admits of determination within narrower limits, a recomputation of the perturbations would lose much of its value and interest, and accordingly the Haarlem Society, in stating the terms of the prize, limit the investigation now demanded to a definitive calculation of the orbit of the comet in 1815, at least we so understand the notification in *Astronomische Nachrichten*, No. 2,264. Allusion is made to NATURE, vol. xix. pp. 268, 366, where we gave references to publications in which the observations of this comet that admit of a new reduction are to be found. The Society at the same time offer a prize for a critical examination of Serpieri's theory of the zodiacal light, "especially if it is to be sought within or without the earth's atmosphere," and it does not clearly appear from the article in the *Astronomische Nachrichten*, whether one prize is intended to apply to the two subjects; we can hardly suppose that this is the case, as it seems unlikely that any one person would engage upon problems of so widely different a character.

THE NEW COMET.—The elements of the comet discovered by Mr. Lewis Swift do not bear resemblance to those of any comet previously computed, and it does not appear that the body is one of any special interest. The perihelion passage took place towards the end of April, and the comet is now slowly receding from the earth. From the direction of its path, so far as position is concerned, it might remain visible for a considerable time, but its brightness is stated to be sensibly diminishing.

THE COMET 1759 (III.).—The following orbit of this comet by Mr. Hind rests upon a new reduction of some of the observations made at Paris, and upon Cassini de Thury's last observation as given by Pingré.

Perihelion passage, 1759, Dec. 16·84108 G.M.T.

	° ′ ″	
Longitude of perihelion	138 28 35	Mean equinox 1760·0.
,, ascending node ...	79 50 4	
Inclination	4 52 31	
Log. perihelion distance	9·9848692	

Motion—retrograde.

This is the comet which became suddenly visible in Western Europe on January 8, 1760, when its distance from the earth was within 0·075 of the earth's mean distance from the sun.

VARIABLE STARS.—The following are Greenwich times of geocentric minima of Algol according to Prof. Schönfeld's elements, from the middle of July to the middle of October:—

	h. m.		h. m.		h. m.
July 15 ...	12 29·2	Aug. 27 ...	12 37·4	Sept. 22 ...	7 54·4
18 ...	9 17·8	30 ...	9 25·9	Oct. 6 ...	15 57·6
Aug. 4 ...	14 9·1	Sept. 16 ...	14 17·2	9 ...	12 46·2
7 ...	10 57·7	19 ...	11 5·8	12 ...	9 34·9
24 ...	15 48·9				

The rise in brightness of *Mira Ceti* to its maximum on September 11 may be well observed this summer. S Cancri will be at a minimum on September 18 at 10h. 4m. On the variations of the latter star Schönfeld's memoir published at Mannheim in 1872 may be advantageously consulted.

GEOGRAPHICAL NOTES

THE new number of the Geographical Society's periodical contains Mr. Keith Johnston's notes on "Native Routes in East Africa, from Dar-es-Salaam towards Lake Nyassa," accompanied by a very interesting map, in which are embodied the particulars gleaned by Mr. Johnston from native travellers. This paper is followed by Prof. Geikie's lecture on geographical evolution, of which an abstract appeared in NATURE, vol. xix. p. 490, and several pages are next devoted to a not very happy attempt to present the salient geographical features of Mr. Ryall's account of his explorations in Western Thibet, which forms one of the appendices of the *General Report* of the operations of the Survey of India for 1877-8. Among the geographical notes we find intimations that the science lectures are to be discontinued, and that the Council have arranged to provide means of instruction and training for intending travellers. There is also a note of Mr. M. C. Doughty's visit to El-Hejjer, a reported Troglodyte city in North-west Arabia, which disposes of singular fables that have been accepted by some learned Orientalists.

THE question of the availability of elephants in African exploration, lately so much discussed, is now about to be put to the crucial test of experiment. The four elephants presented by the Indian Government to the King of the Belgians for the use of his expedition have arrived safely at Zanzibar, and have been landed near Dar-es-Salaam, not, however, without some difficulty, as the following extract from a letter written by a lady who witnessed the scene will show:—"We never thought the first elephant could get alive to shore. It swam more than a mile in distance, and was in the water for more than an hour. Long after it was half way it would keep turning round and trying to come back to the ship. I cannot describe to you the excitement there was on board. I fairly cried once with anxiety and excitement, it would have been too horrible to see it drowned! It tried to climb up the ship's side once. It was pouring with rain, which made things seem more dismal; we were all wet through, but nobody cared. We had to get our experience as we went on, as no one knew anything about elephants on landing. We managed the other three much better, and made the Captain take the ship nearer in shore. Capt. Carter has stayed over there to take the elephants to Dar-es-Salaam, a distance of four miles, and will stay to see them comfortably settled."

THE *Novoye Vremya* gives some further news as to the progress of the Russian traveller, Col. Prjevalsky. The distance from the Saisan port to the River Buguluk, in the southern Altai mountains, was accomplished by the Colonel towards the end of April. All this tract is a barren desert, having neither flora nor fauna, though the banks of the River Urungu were found to bear some slight vestiges of vegetation. As for the climate, Col. Prjevalsky describes it as characterised by frost at night-time, with heat and storms during the day. Eight degrees of frost in the morning were often followed by 20 deg. of

heat at noon. Nevertheless, the scientific labours of the expedition had great success, the country being explored in all directions, and the gallant Colonel only hopes to attain as fruitful results in Thibet. He intended advancing to Barkul and Chami, as the shortest way through the southern Altai range.

FROM the Annual Report upon the Survey of the Northern and North-Western Lakes and the Mississippi River, in charge of Major C. B. Comstock and Capt. H. M. Adams, we learn that on Lake Erie the triangulation has been carried from Cleveland, Ohio, to the west end of the lake. The topography and hydrography have been extended to include all of the American shore, and the Canadian shore from Detroit River to Point Pelée. A base-line has been measured near Chicago and the connecting triangulation east has been completed to White Pigeon, Mich. The latitude and longitude of Memphis, Tenn., have been determined, and in connection with Capt. W. S. Stanton, United States Engineers, the longitudes of Fort Laramie, Wyo., Camp Robinson, Neb., and Deadwood, Dak., have been determined. The survey of the Mississippi River has been carried from Mound City, above Memphis, to Scanlon's Landing, Ark., and a line of precise levels has been completed from Memphis, Tenn., to Austin, Miss. A chart of Lake Ontario, coast charts Nos. 1 and 2 Lake Ontario, coast charts Nos. 7, 8, and 9 Lake Michigan, and detail charts Nos. 1, 2, 3, 4, 5, 6, and 7 Mississippi River have been completed.

IN his last report from Saigon, Mr. Consul Tremlett states that the water communication between Saigon, Cholon, and the western provinces of French Cochin China being very circuitous and inadequate to the traffic, the Canal of Cho-goo has been cut from Cho-goo to Soug-tra, being six miles in length and 110 feet broad. This canal is of immense importance to the country between the River Donnai and the Mei-Kong. Another short canal is to be cut near the junction of the Viaco and Soir-ap, two arms of the Donnai. Mr. Tremlett also mentions that a canal which did not attract much attention was opened in 1876, connecting the lower and upper branches of the Mei-Kong; it is 3½ miles long, and opens a more direct course from the south-western parts of the colony to Cholon, the great centre of traffic.

ERNEST MARNO, the well-known Austrian traveller in Africa, who originally formed one of the staff of the Belgian expedition under the late Capt. Crespel, has recently been appointed deputy governor of the province of Galabat in the Soudan. M. Statin, another Austrian traveller, has gone to the region of the Upper Nile, the special object of his journey being meteorological investigations.

MESSRS. S. T. LEIGH AND CO., of Sydney, have issued a map which will be very useful to persons visiting Australia during the approaching exhibition. It shows the Great Western Railway of New South Wales crossing the Blue Mountains, from the Nepean River to Bowenfells, also the localities and natural features of greatest general interest. The map has been compiled on the scale of one geographical mile to an inch by Mr. E. Du Faur, and is intended to accompany some fine photographs of the same region which Mr. Du Faur published about two years back. The more remarkable gorges and cliffs among the mountains are illustrated by dark shading.

NO. 1 of the new volume (36) of *Globus* has the first of a series of articles on the Island of Chios, by Dr. Ad. Testevuide, of that island. There are two papers of considerable ethnological interest: one by M. Andrée on the ethnological boundaries in France, and the other by Dr. Jung, mentioned in next note, on Australian types and sketches. Among the news are some details concerning Severtzov's second journey in the Pamir.

"AUSTRALIEN UND NEUSEELAND" is the title of an historical, geographical, and statistical sketch by Dr. Carl E. Jung, which has just been published at Leipzig (O. Mutze), with ten illustrations.

LAST YEAR'S SOLAR ECLIPSE[1]

WE have received an interesting account of the observations made during the late eclipse in Texas, under the direction of Mr. Waldo. The first part of the Report is chiefly taken up with an account of the determination of the geographical position of Fort Worth. The second part contains the reports of the various observers. Mr. Waldo gives a description of the photographs obtained. Unfortunately the camera had no proper clockwork. An ingenious, though most likely shaky, arrangement was used to correct the sun's motion in altitude, while his motion in azimuth was left to take care of itself. Each point more luminous than the remainder of the sun's corona is therefore drawn out into a line; but this outline of the moon's edge at the beginning and end of totality is sufficient to determine the position of these brighter points. An attempt was made to obtain photographic evidence of the polarisation of the corona, by inserting a double image prism between the lenses of the camera. The result was doubtful. The photographs were examined by Prof. Pickering, who found inequalities in them, which, as far as they go, tend to indicate a tangential polarisation; but in the opinion of Dr. Hastings, the evidence is not conclusive.

Mr. R. W. Willson observed the corona through a 3-inch telescope. By an oversight a red shade was not removed before totality. Through this shade the corona seemed to have a pretty well-defined limit about four or five minutes from the moon's limb. After the shade had been removed, other portions of the corona could be seen, the light of which was nearly as intense as that near the sun's limb; while the ring, which alone was visible through the shade, was not distinguished from the other parts of the corona. These observations would indicate that there is more red light in the corona near the body of the sun than away from it; and this observation is confirmed by Prof. S. H. Lockett, who, in a letter to Mr. Waldo, calls the outer corona "more bluish-white" than the inner corona.

Prof. J. H. Rees made some spectroscopic observations with a two-prism spectroscope. No bright lines were seen; but on widening the slit dark lines were noticed, amongst them especially C and D.

Mr. W. H. Pulsifer made also some spectroscopic observations. He noticed the reversal of the Fraunhofer lines with a tangential slit, and from the length of these lines he determined approximately the thickness of the reversing layer to be about 524 miles. No observations could be made during totality, as the image of the corona on the slit was lost, and could not be found again. The mischief was caused originally by one of the lamps, which went out just before totality. Moral: Don't trust to any lamps during eclipse observations. There is always a gust of wind at the beginning of totality, which is pretty sure to extinguish lamps.

Mr. Seagrave could see the inner corona about thirty seconds before totality.

Several gentlemen have sent in sketches of the corona, which are given on the last of the four plates accompanying the report. The remaining plates are taken up by an enlarged copy of the best photograph obtained, by a sketch illustrating Mr. Willson's report, and by a sketch of the corona made by Prof. Lockett.

ARTHUR SCHUSTER

[1] Report of the Observations of the Total Solar Eclipse, July 29, 1878, made at Fort Worth, Texas. Edited by L. Waldo. (Cambridge: J. Wilson and Son, 1879.)

MOLECULAR PHYSICS IN HIGH VACUA [1]

WHEN I was asked, a month or two ago, to illustrate in this theatre some of my recent researches on molecular physics in high vacua, I exclaimed, "How is it possible to bring such a subject worthily before a Royal Institution audience when none of the experiments can be seen more than three feet off?" If to-night I am fortunate enough to show all the experiments to those who are not far distant, and if I succeed in making most of them visible at the far end of the theatre, such a success will be entirely due to the great kindness of your late secretary, Mr. Spottiswoode, who has placed at my disposal his magnificent induction-coil—not only for this lecture, but for some weeks past in my own laboratory—thus enabling me to prepare apparatus and vacuum tubes on a scale so large as to relieve me of all anxiety so far as the experimental illustrations are concerned.

Before describing the special researches in molecular physics which I propose to illustrate this evening, it is necessary to give a brief outline of one small department of the modern theory of the constitution of gases. It is not easy to make clear the kinetic theory, but I will try to simplify it in this way:—Imagine that I have in a large box a swarm of bees, each bee independent of its fellow, flying about in all manner of directions and with very different velocities. The bees are so crowded that they can only fly a very short distance without coming into contact with one another or with the sides of the box. As they are constantly in collision, so they rebound from each other with altered velocities and in different directions, and when these collisions take place against the sides of the box pressure is produced. If I take some of the bees out of the box, the distance which each individual bee will be able to fly before it comes into contact with its neighbour will be greater than when the box was full of bees; and if I remove a great many of the bees I increase to a considerable extent the average distance that each can fly without a collision. This distance I will call the bee's *mean free path.* When the bees are numerous the mean free path is very short; when the bees are few the mean free path will be longer, the length being inversely proportional to the number of bees present. Let us now imagine a loose diaphragm to be introduced in the centre of the box, so as to divide the number of bees equally. The same number of bees being on each side, the impacts on the diaphragm will be equal; and the mean speed of the bees being the same, the pressure will be identical on each side of the diaphragm, and it will not move.

Let me now warm one side of this division so as to let it communicate extra energy to a bee when it touches it. As before, a bee will strike the diaphragm with its normal mean velocity, but will be driven back with extra velocity, the reaction producing an increase of pressure on the diaphragm. It will be found, however, that although the diaphragm is free to move, the extra strength of the recoil on the warm side does not produce any motion. This at first sight seems contrary to the law of action and reaction being equal. The explanation is not difficult to understand. The bees which fly away from the diaphragm have drawn energy from it, and therefore move quicker than those which are coming towards it; they beat back the crowd to a greater distance, and keep a greater number from striking the diaphragm. Near to the heated side of the diaphragm the density is less than the average, while beyond the free path the density is above the average, and this greater crowding extends to all other parts of the box. Thus it happens that the extra energy of the impacts against the warm side of the diaphragm is exactly compensated by the increased number of impacts on the cool side. In spite therefore of the increased activity communicated to a portion of the bees, the pressure on the two sides of the diaphragm will remain the same. This represents what occurs when the extent of the box containing the bees is so great, compared with the mean free path, that the abrupt change in the velocities of those bees which rebound from the walls of the box produces only an insensible influence on the motions of bees at so great a distance as the diaphragm.

I will next ask you to imagine that I am gradually removing bees from our box, still keeping the diaphragm warm on one side. The bees getting fewer the collisions will become less frequent, and the distance each bee can fly before striking its neighbour will get longer and longer, and the crowding in front of them will grow less and less. The compensation will also diminish, and the warmed side of the diaphragm will have a tendency to be beaten back. A point will at last be reached on the warm side, when the mean free path of the bees will be long enough to admit of their dashing right across from the diaphragm to the side of the box, without meeting more than a certain number of in-coming bees in their flight. In this case the bees will no longer fly quite in the same direction as before. They will now fly less sideways, and more forwards and backwards between the heated face of the diaphragm and the opposed wall of the box. Because of this preponderating motion, and also because they will thereby less effectually keep back bees crowding in from the sides, there will now be a greater proportionate pressure both on the hot face of the diaphragm and on that part of the box which is in front of it. Hence the pressure on the hot side will now exceed that on the cool side of the diaphragm, which will consequently have a backward movement communicated to it.

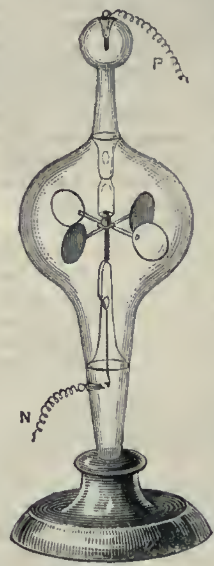


FIG. 1.

I may diminish the size of the bees as much as I like, and by correspondingly increasing their number the mean free path will remain the same. Instead of bees let me call them molecules, and instead of having a few hundreds or thousands in the box let me have millions and billions and trillions; and if we also diminish the mean free path to a considerable extent, we get a rough outline of the kinetic theory of gases. (I may just mention that the mean free path of the molecules in air, at the ordinary pressure, is the ten-thousandth of a millimetre.)

Three years ago I had the honour of bringing before you the results of some researches on the radiometer. Let me now take up the subject where I then left off. I have here two radiometers which have been rotating before you under the influence of a strong light shining upon them.

The explanation of the movement of the radiometer is this—the light, or the total bundle of rays included in the term "light," falling upon the blackened side of the vanes, becomes absorbed, and thereby raises the temperature of the black side: this causes extra excitement of the air molecules which come in contact with it, and pressure is produced, causing the fly of the radiometer to turn round.

I have long believed that a well-known appearance observed in vacuum tubes is closely related to the phenomena of the mean

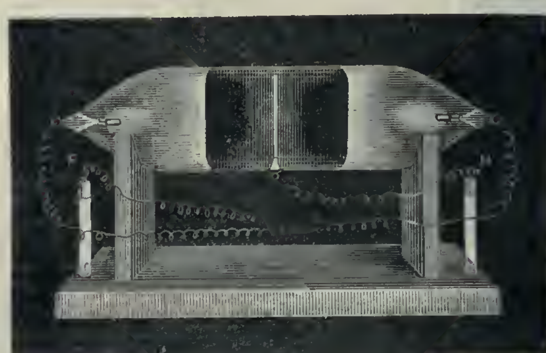

FIG. 2.

free path of the molecules. When the negative pole is examined while the discharge from an induction coil is passing through an exhausted tube, a dark space is seen to surround it. This dark space is found to increase and diminish as the vacuum is varied, in the same way that the ideal layer of molecular pressure in the radiometer increases and diminishes. As the one is perceived by the mind's eye to get greater, so the other is seen by the bodily eye to increase in size. If the vacuum is insufficient to permit the radiometer to turn, the passage of electricity shows

[1] A short-hand report of a lecture delivered at the Royal Institution on Friday, April 4, 1879. By William Crookes, F.R.S. Contributed by the author.

that the "dark space" has shrunk to small dimensions. It is a natural inference that the dark space is the mean free path of the molecules of the residual gas.

The radiometer which has just been turning under the influence of the lime-light is not of the ordinary kind. Fig. 1 will explain its construction.

It is similar to an ordinary radiometer with aluminium disks for vanes, each disk coated on one side with a film of mica. The fly is supported by a hard steel instead of glass cup, and the needle point on which it works is connected by means of a wire with a platinum terminal sealed into the glass. At the top of the radiometer bulb a second terminal is sealed in. The radiometer can therefore be connected with an induction-coil, the movable fly being made the negative pole.

As soon as the pressure is reduced to a few millims. of mercury, a halo of velvety violet light forms on the metallic side of the vanes, the mica side remaining dark. As the pressure diminishes, a dark space is seen to separate the violet halo from the metal. At a pressure of half a millim. this dark space extends to the glass, and positive rotation commences. On continuing the exhaustion the dark space further widens out and appears to flatten itself against the glass, when the rotation becomes very rapid.

You perceive a dark space behind each vane and moving round with it. In the first experiment, radiation from the lime-light falling on the metallic sides of the vanes, produced a layer of molecular pressure which drove the fly round; so here the induction-current has produced molecular excitement at the surface of the vanes forming the negative pole, extending up to the side of the glass.

When the negative pole is in rapid rotation it is not easy to see this dark space, so I have arranged a tube in which the dark space will be visible to all present. The tube, as you will see by the diagram (Fig. 2), has a pole in the centre in the form of a metal disk, and other poles at each end. The centre pole is made negative, and the two end poles connected together are made the positive terminal. The dark space will be in the centre. When the exhaustion is not very great the dark space extends only a little distance on each side of the negative pole in the centre. When the exhaustion is very good, as it is in the tube before you, and I turn on the coil, the dark space is seen to extend for about two inches on each side of the pole.

Here, then, we see the induction spark actually illuminating the lines of molecular pressure caused by the excitement of the negative pole. The thickness of this dark space—nearly two inches—is the measure of the mean free path between successive collisions of the molecules of the residual gas. The extra velocity with which the negatively electrified molecules rebound from the excited pole keeps back the more slowly moving molecules which are advancing towards that pole. The conflict occurs at the boundary of the dark space, where the luminous margin bears witness to the energy of the discharge.

I will endeavour to throw on the screen an illustration of this dark space. A stream of water falls from a small jet on to a horizontal plate of glass. The water spreads over the plate and forms a thin film. The jet of water in the centre, from the velocity of its fall, drives the film of water before it on all sides, raising it into a ring-shaped heap. As I diminish the force of the jet the ring contracts; this is equivalent to the exhaustion getting less. When I increase the force of water the ring expands in size, the effect being analogous to an increase of exhaustion in my tubes. The extra velocity of the falling particles of water drives the in-coming particles of water before them, and raises a ridge round the side which exactly represents the luminous halo to the dark space to be seen in this tube.

If, instead of a flat disk, a metal cup is used for the negative pole, the successive appearances on exhausting the tube are somewhat different. The velvety violet halo forms over each side of the cup. On increasing the exhaustion the dark space widens out, retaining almost exactly the shape of the cup. The bright margin of the dark space becomes concentrated at the concave side of the cup to a luminous focus, and widens out at the convex side. When the dark space is very much larger than the cup, its outline forms an irregular ellipsoid drawn in towards the focal point. Inside the luminous boundary a dark violet light can be seen converging to a focus, and, as the rays diverge on the other side of the focus, spreading beyond the margin of the dark space; the whole appearance being strikingly similar to the rays of the sun reflected from a concave mirror through a foggy atmosphere. This proves a somewhat important point; it shows that the molecules thrown off the excited negative pole leave it in a direction almost normal to the surface.

I can illustrate this property of the molecular rays by an experiment. This diagram (Fig. 3) is a representation of the tube which is before you. It contains, as a negative pole, a hemi-cylinder (*a*) of polished aluminium. This is connected with a fine copper wire, *b*, ending at the platinum terminal, *c*.

FIG. 3.

At the upper end of the tube is another terminal, *d*. The induction-coil is connected so that the hemi-cylinder is negative and the upper pole positive, and when exhausted to a sufficient extent, as is the case with this tube, the projection of the molecular rays to a focus is very beautifully shown. The rays are driven from the hemi-cylinder in a direction normal to its surface; they come to a focus and then diverge, tracing their path in brilliant green phosphorescence on the surface of the glass.

You will notice that the rays which project from the negative pole and cross in the centre have a bright green appearance; that colour is entirely due to the phosphorescence of the glass. At a very high exhaustion the phenomena noticed in ordinary vacuum tubes when the induction spark passes through them—an appearance of cloudy luminosity and of stratifications—disappears entirely. No cloud or fog whatever is seen in the body of the tube, and with such a vacuum as I am working with in these experiments—about a millionth part of an atmosphere—the inner surface of the glass glows with a rich green phosphorescence, the intensity of colour varying with the perfection of the vacuum. It scarcely begins to show much before the 800,000th of an atmosphere. At about a millionth of an atmosphere the phosphorescence is very strong, and after that it begins to diminish

FIG. 4.

until there are not enough molecules left to allow the spark to pass.[1]

I have here a tube which will serve to illustrate the dependence of the green phosphorescence of the glass on the degree of perfection of the vacuum (Fig. 4). The two poles are at *a* and

[1] 1·0 millionth of an atmosphere = 0·00076 millim.
1315·789 millionths of an atmosphere = 1·0 millim.
1,000,000 " " " = 760·0 millims.
" " " " = 1 atmosphere.

b, and at the end (*c*) is a small supplementary tube connected with the other by a narrow aperture, and containing solid caustic potash. The tube has been exhausted to a very high point, and the potash heated so as to drive off moisture and deteriorate the vacuum. Exhaustion has then been re-commenced, and the alternate heating and exhaustion have been repeated until the tube has been brought to the state in which it now appears before you. When the induction spark is first turned on nothing is visible—the vacuum is so high that the tube is non-conducting. I now warm the potash slightly, and liberate a trace of aqueous vapour. Instantly conduction commences, and the green phosphorescence flashes out along the length of the tube. I continue the heat, so as to drive off more gas from the potash. The green gets fainter, and now a wave of cloudy luminosity sweeps over the tube, and stratifications appear. These rapidly get narrower, until the spark passes along the tube in the form of a narrow purple line. I take the lamp away, and allow the potash to cool; as it cools, the aqueous vapour, which the heat had driven off, is re-absorbed. The purple line broadens out, and breaks up into fine stratifications; these get wider, and travel towards the potash tube. Now a wave of green light appears on the glass at the other end, sweeping on and driving the last pale stratification into the potash; and now the tube glows over its whole length with the green phosphorescence. Would time allow I might keep it before you, and show the green growing fainter and the vacuum becoming non-conducting; but time is required for the absorption of the last traces of vapour by the potash, and I must pass on to the next subject.

Fig. 5.

This green phosphorescence is a subject that has much occupied my thoughts, and I have striven to ascertain some of the laws governing its occurrence. I soon perceived that the phosphorescence was not in the body of the tube itself, but was entirely on the surface of the glass. Another peculiarity of the rays producing this green phosphorescence is that they will not turn a corner in the slightest degree. Here is a V-shaped tube (Fig. 5), a pole being at each extremity. The pole at the right side (*a*) being negative, you see that the whole of the right arm is flooded with green light, but at the bottom it stops sharply, and will not turn the corner to get into the left side. When I reverse the current, and make the left pole negative, the green changes to the left side, always following the negative pole, leaving the positive side with scarcely any luminosity.

In the ordinary phenomena exhibited by vacuum tubes—phenomena with which we are all familiar—it is customary, for the more striking illustration of their contrasts of colour, to have the tubes bent into very elaborate designs. The positive luminosity caused by the phosphorescence of the residual gas follows all the convolutions and designs into which skilful glass-blowers can manage to twist the glass. The negative pole being at one end and the positive pole at the other, the luminous phenomena seem to depend more on the positive than on the negative at an ordinary exhaustion such as has hitherto been used to get the best phenomena of vacuum tubes. I have here two bulbs (Fig. 6), alike in shape and position of poles, the only difference being that one is at an exhaustion equal to a few millimetres of mercury—such a moderate exhaustion as will give stratifications or the

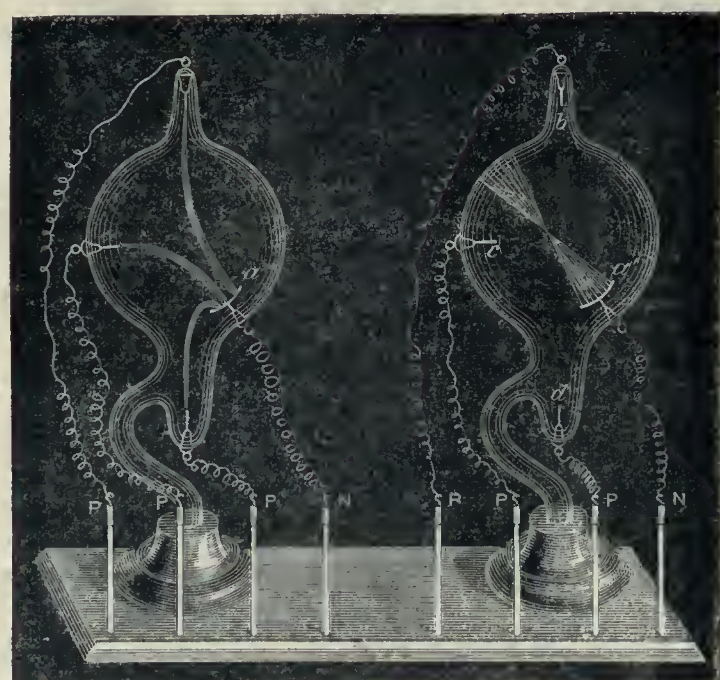

Fig. 6.

ordinary luminous phenomena—whilst the other is exhausted to about the millionth of an atmosphere. I will first connect the moderately exhausted bulb with the induction-coil, and, retaining the pole at one side (*a*) always negative, I will put the positive wire successively to the other three poles with which the bulb is furnished. You will see that as I change the position of the positive pole, the line of violet light joining the two poles changes. In this moderately exhausted bulb, therefore, the electric current always chooses the shortest path between the two poles, and moves about the bulb as I alter the position of the wires.

This, then, is the kind of phenomenon we get in ordinary exhaustions. I will now try the same experiment with a tube that is highly exhausted, and, as before, will make the side pole (*a'*) the negative, the top pole (*b*) being positive. Notice how widely different is the appearance from that shown by the last bulb. The negative pole is in the form of a shallow cup. The bundle of rays from the cup crosses in the centre of the bulb, and thence diverging, falls on the opposite side as a circular patch of green light. As I turn the bulb round you will all be able to see the faint blue focus and the green patch on the glass. Now observe, I remove the positive wire from the top, and connect it with the side pole (*c*). The green patch from the divergent negative focus is still there. I now make the lowest pole (*d*) positive, and the green patch still remains where it was at first, unchanged in position or intensity.

This, then, gives us another fact which brings us a little nearer to the cause of this green phosphorescence. It is this—that in the low vacuum the position of the positive pole is of every importance, whilst in a high vacuum it scarcely matters at all where the positive pole is; the phenomena seem to depend entirely on the negative pole. In very high vacua, such as we have been using, the phenomena follow altogether the negative pole. If the negative pole points in the direction of the positive, all very well, but if the negative pole is entirely in the opposite direction it does not matter; the line of rays is projected all the same in a straight line from the negative.

(*To be continued.*)

NOTES

THE following grants have just been made from the Research Fund of the Chemical Society:—30*l*. to Mr. W. Whitley Williams for experiments on an improved method of organic analysis; 25*l*. to Mr. M. M. Pattison Muir, of Caius College, Cambridge, for determining the physical constants and chemical habitudes of certain bismuth compounds; 15*l*. to Mr. J. M. Thomson for experiments on the action of isomorphous bodies in exciting the crystallisation of super-saturated solutions; 50*l*. to Dr. Wright for continuing his researches on chemical dynamics; 25*l*. to Mr. F. D. Brown for continuing his researches on the theory of fractional distillation; 30*l*. to Mr. Bolas for an investigation of certain chromium compounds; 20*l*. to Mr. F. R. Japp for an investigation of the action of organo-zinc compounds on quinones; and 100*l*. (the De la Rue donation) to Dr. H. E. Armstrong for the determination of certain physical properties, especially refractive indices, of typical chemical compounds. Dr. De la Rue has announced his intention of presenting the fund with another 100*l*. This will be the third donation of that amount which the fund has received from him.

THE Council of the Royal Society of Edinburgh have decided to award the Makdougall Brisbane Prize for the biennial period 1877–78 to Prof. Geikie for his "Memoir on the Old Red Sandstone of Western Europe," Part I., published in the Society's *Transactions*, and forming part of his valuable contributions to geology.

GENERAL MYER, of the U.S. Signal Corps, has arrived in Paris from Rome, on his way to London, where he will have an interview with the Meteorological Board for the purpose of establishing an understanding in matters of common interest, especially on the subject of exchanging telegrams with America, so that both nations may enjoy a daily summary of the weather on each continent.

M. LISSAJOUS has been elected a Foreign Corresponding Member in the Paris Academy, Section of Physics, in place of the late Dr. von Mayer.

DR. FAIVRE, the Dean of the Lyons Faculty of Sciences, has been run over by a cart when conducting a number of pupils to a botanical excursion. His constitution was so dreadfully shaken that he died after a few days of suffering. Dr. Faivre was opposed to the Darwinian theory, and has published books against the mutation of species. His most important publication was a review of Goethe's scientific works.

THE collection of living reptiles in the Jardin des Plantes, Paris, has just received an interesting addition in the shape of three living examples of the rare East-Indian serpent known to naturalists as *Acrochordus javanicus*. These snakes belong to quite a peculiar type of the Ophidian order, and are, in fact, truly fresh-water snakes, living among rocks wholly immersed beneath the surface, and but seldom rising up to inhale air. They are quite harmless, and allow themselves to be handled without difficulty. The food of the *Acrochordus* is supposed to be fruit—a most anomalous diet for a snake, if this is really the case, but the specimens at Paris have not yet shown a taste for eating anything.

WITH reference to a recent note, the Abbé Moigno writes us from Rome that he has not resigned the editorship of *Les Mondes*, which he has edited for twenty-seven years. He has gone to Rome to lay at the feet of the Pontiff the results of many years laborious work, but will return as he went, not a Cardinal, but the *doyen* of scientific journalists, eager for progress in all directions. We sincerely wish the Abbé many more years to carry on the work of editing his well-known journal, that has for so long done good service to science.

AMONG other recommendations made at the recent meeting of the International Meteorological Congress was the adoption of the meridian of Greenwich as the starting-point for the construction of synoptic weather charts. In the event of another meridian being used in the construction of meteorological charts the Congress recommended that the difference of longitude between the meridian employed and that of Greenwich should be stated on the chart.

A TERRIFIC thunderstorm broke over Paris on June 28 at six o'clock in the morning. There were a number of casualties; one of the most singular occurred in a room in the rue de Clichy, No. 34, where two old ladies live. One of them was drinking milk from a cup, which was knocked from her hands and could not be found, although the lady escaped unhurt. In the *rez-de chaussée* was the shop of a chemist, where a number of bottles were broken, and in the same house a bed, where a woman had taken refuge, was cut into two equal parts.

IN a balloon ascent which took place at Rouen on June 15 last with a large balloon, the occupants of the car found at 12,000 metres from the earth a cloud where the cold was so intense that small icicles were seen suspended to the beards and moustaches of the travellers.

THE Parkes Museum of Hygiene, founded as a memorial of the late Dr. E. A. Parkes to promote the study of all matters bearing upon the health of the community or the individual, was formally opened on Saturday by the Home Secretary, in the rooms on the top floor of the building lent by the council of University College until separate and suitable premises can be obtained. At present there have been brought together apparatus, specimens, books, reports, and drawings illustrative of matters connected with engineering and local hygiene; architecture, including general designs and details of buildings, methods of constructing hospitals, blocks of artisans' dwellings, &c., with

specimens of appliances for necessary sanitary arrangements, drainage, ventilation, and lighting; the furnishing of buildings, public and domestic, clothing, food; and the preservation of health and the relief of sickness. At present the collection is incomplete, but the committee hoped that funds and material would be forthcoming to make the Parkes Museum a national and a useful institution worthy of the important subject which it illustrated and the great name it bore. Prof. Huxley, who was present, expressed a hope that Mr. Cross would use his influence with the Government and with the House of Commons to stay a movement which appeared intended to dam back the stream of education and prevent the lower classes from gaining the knowledge they so much needed.

A MEETING of ladies and gentlemen interested in Japanese art, literature, folk-lore, &c., will be held to-morrow at the Royal Asiatic Society, 22, Albemarle Street. The meeting is called together for the purpose of establishing in London a central institution, with the following objects:—To bring into closer communication admirers and students of Japanese art, literature, &c.; and to collect, record, and disseminate information relative to Japan. To encourage residents in Japan, and the Japanese, to collect such material. To enlist the cordial co-operation of scientific and literary societies, and individuals, in extending the usefulness of the Institution. To publish proceedings, notes, queries, and other interesting matter; and to facilitate this branch of research and study. After the business is concluded, an "Old Resident" will communicate some interesting facts about Japan, illustrated by photos, &c., from his collection, and discussion will follow.

SOME attention has recently been drawn in the *Gardeners' Chronicle* to tea prepared in St. Michael, Azores, from plants grown in that island. It seems that two Chinese tea-growers have been sent for by the Agricultural Society of St. Michael, and after a careful examination of the tea-plantations they pronounced the plants as belonging to the very best varieties grown in China. It is prophesied that "the time is not far off when tea from St. Michael will come to the European market and prove to be of a very good quality." In a subsequent number of the *Gardeners' Chronicle*, however, Mr. Elwes points out the difficulties to be contended with in a competition with India and China in the production of tea, notably the price of land, the cost of labour, the temperature, extent of rainfall, &c. The first outcome of this tea growing in the Azores is shown in a sample recently received at the Kew Museum from Señor José de Canto. This sample is of good appearance through perhaps somewhat over roasted, the smell also is good, and the flavour of the infusion by no means to be despised.

THE new fodder grass *Euchlæna luxurians* known as the Teosinte, and which has attracted considerable attention of late, is reported from Ceylon as growing well, having been introduced from Java. The stems have attained in the former island the height of eight feet in three months from the time of sowing. The plant is stated to be unsuitable for cultivation at high elevations, but it is hoped that after a time it would become acclimatised to them. At the time the above was written the seeds were being distributed in several districts.

DR. SCHOMBURGK in his "Report on the Progress and Condition of the Botanic Garden and Government Plantations" of Adelaide, South Australia, for the year 1878, gives, as usual, a great deal of consideration to plants of economic interest. In the experimental ground many of the well-known British fodder grasses have been grown and produced satisfactory results. Dr. Schomburgk, however, points out the almost impossibility of stocking runs with artificial grasses on account of the large extent of pastoral land, and of the insuperable difficulty arising from climate and drought, to which some parts of the colony, especially the north, are often subjected. *Euchlæna luxurians* has not been introduced long enough to give any practical results. It is hoped, however, that the plant will turn out a great acquisition to the summer fodder plants of Australia. On the subject of flower farming for perfumery purposes there is no doubt that the Australian colonies offer special advantages for this branch of culture. Dr. Schomburgk thinks favourably of the scheme, but considers it unadvisable to manufacture the scents in the colony on account of the greater perfection with which this kind of work is done at home. As an illustration of the importance of this single use of flowers Dr. Schomburgk says:—If we consider that British India and Europe consume about 150,000 gallons of handkerchief perfume yearly, and the English revenue from Eau-de-Cologne alone is about 8,000*l*. a year; that the total revenue from imported perfumes is estimated at about 40,000*l*., and that one great perfume distillery at Cannes in France uses yearly about 100,000 lbs. of Acacia flowers (*Acacia farnesiana*), 140,000 lbs. of rose-flower leaves, 32,000 lbs. of jasmine blossoms, 20,000 lbs. of tuberose, together with a great many other sweet herbs, we may judge of the immense quantity of material used for perfume. It is satisfactory to find that the Colonial Parliament has granted a sum of 1,000*l*. towards the erection of a new building for the Museum of Economic Botany; this sum, however, it is expected, will be supplemented by a further vote, so that a building of sufficient size, to meet the requirements of the next generation, may be erected. The design, as already furnished, is for a building in the Romanesque style, 100 feet long by 36½ feet wide. The show cases will be fixed between the windows and at right angles with them on the plan adopted in the New Museum at South Kensington. From the promises of specimens, together with those already contained in the present museum, amounting to about 2,000 objects, it is expected that the museum when finished will form a very important adjunct to the gardens. The Report concludes with a notice of the *Phylloxera vastatrix*, or vine disease, which is enlarging its borders so much as to threaten a serious visitation in Australia.

SEVERAL remarkable results have been recently obtained by Herr Kohlrausch in his researches on the electric conductivity of aqueous solutions (*Annalen der Physik*), and especially with regard to the influence of temperature on the conducting power of liquids. Thus concentrated soda-lye, which, at a temperature of $-10°$ conducts badly, acquires, under action of heat, a conducting power which increases regularly and with very great rapidity, so that at $+80°$ the liquid conducts a *hundred* times better than at $-10°$. A solution of bisulphate of potash behaves quite differently; its conducting power increases very slowly with the temperature, up to a temperature of 60°, at which there is a maximum. From this point the conductivity remains nearly constant, as the temperature is raised. Studying solutions of sulphate of soda, which are known to present at 33° a remarkable peculiarity, due to the proportion, more or less, of water of crystallisation, Herr Kohlrausch found nothing peculiar in the conducting power. This seems to prove that water of crystallisation does not play any part in the conductivity of liquids for electricity.

IN addition to his astronomical paper, Admiral Mouchez is preparing the organisation, at the Observatory, of a High School of Astronomy composed of pupils from the Polytechnic and Normal Schools, and licenciés en sciences, mathematiques, et physiques. The salary of successful pupils will be 1,800 francs a year, and positions will be secured for them in the French national observatories. The school will also admit a number of free students, who will have the advantage of the use of the instruments of the observatory.

THE New York correspondent of the *Daily News* telegraphs as follows:—"Mr. Edison has obtained a dynamometer of suffi-

cient delicacy to measure every one-hundredth of horse-power. With this instrument he can calculate the cost of the electric light to the minutest detail. He has demonstrated that from 80 to 90 per cent. of energy is converted into light, and that six electric lights are supplied from one horse-power at one-third the cost of gas. He maintains that the problem of applying the electric light to domestic use has been practically solved, but admits that a great mass of detail remains to be worked out. He has satisfied himself that platinum can be supplied in large quantities so as to reduce the expense.

THE forests of Central Nevada appear (from the accounts of Mr. Sargent, who visited the region last year, and writes about them in *Silliman's Journal* for June) to be miserably poor in extent, productiveness, and especially in number of species. Yet they are of immense value, as regulating and protecting the rare and uncertain streams on which the agriculture of Nevada depends, and furnishing a large population with fuel and lumber, a population practically cut off from outside supply. Mr. Sargent laments the wasteful destruction of forest which follows every new discovery of the precious metals in that region, both on account of the immense age of these forests, and of the impossibility of restoration; and he thinks government should check it. The central Nevada forests consist of but seven species, the juniper (*Juniperus californica*, var. Utahensis) and nut pine (*Pinus monophylla*, Torr.), being the most common. Mountain mahogany (*Cercocarpus ledifolius*) comes next, probably the only North American wood heavier than water, and furnishing the common and cheapest fuel. The other species are the red cedar, the aspen, and two of pine. A comparison which Mr. Sargent makes, of the arborescent vegetation of Nevada with that of the region lying directly east and west of the Great Basin, brings out still more clearly the remarkable poverty of the former.

A VERY ingenious application of electricity to the purposes of navigation has recently been effected by Mr. Henry A. Severn, of Herne Hill, who has succeeded in producing a mariner's compass which enables the captain or officer in charge to hear, by the ringing of a bell, when the vessel is out of the ordered course. The whole of the apparatus is contained in a small box which is easily carried about, and is intended, as a rule, to be placed in the captain's cabin. Over the card are two index hands, which can be adjusted to any angle allowing of greater or less deviation in steering to either the port or starboard side. Assuming the captain, on quitting the deck, to have given instructions to steer the ship on a certain course, he sets the index hands to a certain angle, allowing the steersman a given latitude for deviation either to port or starboard of that course. Should the ship be steered off her course beyond the limit allowed on either side an electric alarm-bell rings instantaneously and, moreover, continues ringing until the right course is resumed. The metal point on which the card is hung is insulated from the compass bowl, and to it is attached a wire from one pole of a small battery. About an inch above the card, placed parallel to its surface and attached to its metal centre (which is insulated from the needle) is an arm of metal reaching nearly to the edge of the card. This arm is, therefore, in metallic communication with the wire from the battery already referred to. The glass lid of the compass has a short brass rod working within a tube passing through it. These are severally attached to two brass milled heads above the glass lid and to the two movable index-hands beneath the glass. These are in metallic contact with the brass-work of the compass, and this with the other pole of the battery. Beneath the outer extremities of the index-hands are suspended two pieces of platinum wire about three-quarters of an inch long. These hands can, by means of the two milled heads, be moved round to any position over any point of the card. Hence they admit of being placed on either side and equally distant or otherwise from the end of the metal arm on the card. It will thus be seen that whenever the platinum wires come into contact with the metal arm on the card the circuit is completed. The electric bell being placed in the circuit sounds whenever such contact takes place. Two bells of different tone can be used, and thus the instrument will indicate to the captain whether the deviation in steering is to port or starboard.

WE have received an interesting *Jahresbericht* of the Natural History Society of Wisconsin, which is evidently largely composed of Germans, the Report being in that language.

WE have on our table the following books:—"The Human Species," A. de Quatrefages (C. Kegan Paul); "Practical Photography," Part 1, O. E. Wheeler (*Bazaar* Office); "Modern Meteorology" (Ed. Stanford); "Mechanics," Prof. R. S. Ball (Longmans); "The Application of Generalised Co-ordinates to the Kinetics of a Material System," H. W. Watson and S. H. Burbury (Clarendon Press); "Galileo Galilei," Karl von Gebler (Kegan Paul); "What is Truth," John Coutts (F. Pitmann); "Sulphuric Acid and Alkali," Vol. i., George Lunge (Van Voorst); "Elementary Arithmetic and How to Teach It," G. Ricks (Isbister and Co.); "Supplement to a Handbook of Chemical Manipulation," C. G. Williams (Van Voorst); "Town and Window Gardening," C. M. Buckton (Longmans); "Der Process Galilei's und die Jesuiten," Dr. F. H. Reusch (Edw. Weber, Bonn); "Parasites, a Treatise on the Entozoa of Man and Animals," T. Spencer Cobbold, M.D. (Churchill); "Elements of South-Indian Palæography," A. C. Burnett (Trübner); "Twenty Lessons in Inorganic Chemistry," W. G. Valentine (W. Collins); "Observed Lunar Distances," John B. Pearson (Bell and Sons); "Floral Dissections," Rev. G. Henslow (Edw. Stanford); "Contributions to our Knowledge of the Arctic Regions," Part 1 (Edw. Stanford); "Proceedings of the Aberdeenshire Agricultural Association," Sessions 1878; "A Manual of Scientific Terms," Rev. James Stormouth (Maclachlan and Stewart, Edinburgh); "Hand List of Mollusca in the Indian Museum," Part 1, Godfrey Nevill (Calcutta); "Chronological History of Plants" Charles Pickering (Trübner); "Report of New York State Survey, 1878," James F. Gardner; "Pontresina and its Neighbourhood," J. M. Ludwig (Stanford); "Description physique de la République Argentine," Vols. ii. and v., and Atlas, &c., Dr. H. Burmeister (Paris, F. Savy); "British Birds," G. Peter Moore (J. van Voorst); "A Hunting Expedition to the Transvaal," D. Fernandes das Nives (Bell); "Origin of the Laws of Nature," Sir Edw. Beckett, Bart. (S.P.C.K.); "Lectures on Practical Astronomy," Rev. J. Challis (Deighton, Bell, and Co.); "Arithmetic," J. W. Marshall (Marcus Ward); "Scientific Lectures," Sir John Lubbock (Macmillan and Co.); "Agricultural Botany, Turnip-singling," A. Stephen Wilson (Smith, Aberdeen); "The Rights of an Animal," E. B. Nicholson (Kegan Paul); "Commercial Organic Analysis," Vol. i., Alf. Allan (Churchill); "Demonology and Devil-Lore," 2 vols., M. D. Conway (Chatto and Windus); "Atlas of Histology," Part 5, Smith and Klein (Smith, Elder).

THE additions to the Zoological Society's Gardens during the past week include a Crested Pigeon (*Ocyphaps lophotes*) from Australia, presented by the Rev. A. H. Glennie; two Lesser Redpoles (*Linota linaria*), British, presented by Dr. Bree, F.Z.S.; a Common Lobster (*Homarus vulgaris*), British Seas, presented by Mr. G. H. Jones, F.Z.S.; two Black-tailed Godwits (*Limosa melanura*), British, two Beautiful Parrakeets (*Psephotus pulcherrimus*) from Australia, four White Storks (*Ciconia alba*), European, two Tuatera Lizards (*Sphenodon punctatus*) from New Zealand, purchased; two Geoffroy's Doves (*Peristera geoffroii*), three Spotted-billed Ducks (*Anas pœcilorhyncha*), three Australian Wild Ducks (*Anas superciliosa*), three Chilian Pintails (*Dafila spinicauda*), bred in the Gardens.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

MR. AND MRS. HENRY SIDGWICK contribute each 500*l*. to the building fund (11,000*l*. being required) for the new hall to be built at Newnham, Cambridge, for women students, under the "Newnham College Association" for the advancement of education and learning among women in Cambridge. Miss Clough, the principal of Newnham Hall, whose unpaid services are of incalculable value, also gives 500*l*. to this new building, which will include lecture-rooms, &c., as well as residence for thirty. Prof. and Mrs. J. C. Adams, Dr. and Mrs. Bateson, Mr. and Mrs. Peile, &c., are among the large donors, and the Rev. Coutts Trotter, of Trinity College, is a donor of 100*l*.

THE Chemical Laboratory of Newnham Hall, which has cost over 1,000*l*., is now complete, and will be available for all the students of the Newnham Association. So also will be the Gymnasium and Garden. The Old Newnham Hall company is now merged in the new association, differing from the former in the contributors not being permitted to receive any profits. It is needless to add that the old association did not actually receive any profits, though registered as an ordinary "limited" liability company.

THE main purpose of the Irish University Bill, introduced to the House of Lords on Monday by Government, seems to be the creation of an institution similar to that of London University, prepared to grant degrees to all comers. In order to do this Government propose to establish a new University, to consist of a Chancellor and Senate to be appointed by the Crown, and not to exceed thirty-six in number. But though nominated in the first instance by the Crown, arrangements would be made to fill up a certain number of the vacancies afterwards, so that Convocation might have the election of six members of the Senate. The Government proposed, with regard to the Convocation, that it should consist of the graduates who had obtained their degrees in this University, or any one who might be transferred to or become graduates from the other University. The Government proposed that the Senate should elect the Vice-Chancellor, and also that the new University thus constituted should appoint examiners and conduct examinations for matriculation and degrees, and that it should confer degrees in all faculties except theology. They proposed that those degrees should be granted without regard to residence in any particular college, that the examinations for those degrees should be with regard to the standard of efficiency only, and that the degrees should be conferred on all who came up to the standard, and they proposed that there should not be any professors or lecturers connected with the University, thus following the example of the University of London. The Government are of opinion that steps should be taken for the dissolution of Queen's University, and that graduates of Queen's should become graduates of the new University, and those who were matriculated students of one should be so of the other, and possess all the same privileges and advantages in the new University as they did in Queen's.

FIVE years ago, when the late Lord Lawrence publicly presented the first Mortimer Scholarship Prize, Prof. Huxley made a speech which has proved prophetic. It was to the effect that the ladder of Board School education planted in the gutter might land such lads as Baker in the highest universities. That lad enjoyed his Mortimer Scholarship (worth 30*l*.) one year. He then obtained a scholarship in the City of London School. In four years more he obtains an open scholarship in Trinity College, Cambridge, at seventeen years of age. An immediate result of this success of the Elementary Education Act is that the Brewers' Company have since presented two scholarships to the London School Board.

IT was stated in Parliament on Monday that a petition having been presented to the Queen in Council, praying Her Majesty to grant a charter for a new Northern University, to be called the Victoria University, Her Majesty had been advised to grant the petition.

SCIENTIFIC SERIALS

Annalen der Physik und Chemie, No. 5.—From experiments here described, on magnetisation of steel during the hardening process, Herr Holtz concludes that the method offers no advantages in practice. Magnets can, indeed, be thus made six times as strong as by the ordinary method, but this holds good only for extremely weak magnetising force; as you increase the force the difference rapidly decreases, and ere long becomes in favour of the ordinary method.—Herr Schellbach and Herr Boehn describe some instructive effects got on plates covered with carbon-dust placed under a discharger of a Leyden jar. Various devices were introduced for reflection, &c., of the sound-waves, whose mechanical action is indicated by the resultant figures on the plates.—Herr Wroblewski finds that a tenfold increase of the viscosity of water (by dissolving a crystalloid or colloid in it) produces only a five or six-fold diminution of the value of the constant for diffusion of carbonic acid in pure water.—The lowering of tone undergone by a sounded tuning-fork when immersed in liquids having been attributed by Herr Auerbach to the circumstance that kinetic energy is dispersed in incompressible liquids in another way than in gases (the changes of state in liquids being supposed to occur isothermally, in gases isentropically), Herr Kolacek offers another explanation based on mechanical principles.—In an inaugural dissertation Herr Freund writes on some galvanic properties of aqueous metal-salt solutions, his experiments having been made by Paalzow's method; and the results for sulphate of copper solution differing about 5 per cent. from those formerly obtained by Herr Beetz, he offers an explanation of this; which, however, Herr Beetz rejects, adhering to his own numbers.—Herr Ketteler contributes a paper on the theory of double refraction, and Herr Rammelsberg writes on some topics in mineralogical chemistry.

Morphologisches Jahrbuch, vol. 5, part 1.—This number contains no fewer than thirteen lithographic plates. Three of these illustrate Oscar Hertwig's second part of his memoir on the piscine dermal skeleton. He deals now with the ganoids (Lepidosteus and Polypterus).—R. S. Bergh, on the early development of the ovum of *Gonothyræa loveni* (Allman), 2 plates, 40 pages.—G. Born, the nasal cavities and passages of the amniotic vertebrata (3 plates, and about 80 pages).—O. Kling on *Craterolophus tethys*, a contribution to the anatomy and histology of the Lucernaridæ (3 plates, 26 pages).—A. Rauber, on the occurrence of budding among the vertebrata (2 plates).

Zeitschrift für wissenschaftliche Zoologie, vol. 32, part 2.—J. E. Boas, the teeth of the Saroids (25 pages).—R. Wiedersheim, the anatomy of *Amblystoma weismanni*, with two large coloured plates.—R. Greef, the pelagic annelids of the Canary Islands (45 pages, 3 plates); with discussions on the comparative anatomy of the Tomopteridæ, and figures and descriptions of Pontodora, &c., and several new species of Tomopteris.—H. Simroth, on the locomotion of Limax; two plates figuring *L. cinereoniger*.—J. Ciamician, on the histology and embryology of *Tubularia mesembryanthemum* (25 pages, 2 plates).

Kosmos, vol. 3, part 1, April, 1879.—The first article, "Natural Science in the Middle Ages," by Fritz Schultze, refers especially to Roger Bacon.—The controversy about *Planorbis multiformis* (1st art.), by F. Hilgendorf, is, among other figures, illustrated by a series of outlines of the different varieties of *P. multiformis*, as seen in section, &c., and referring to Sandberger's views.—Hermann Müller contributes an article of 16 pages, on Samuel Butler's "Life and Habit."

Reale Istituto Lombardo di Scienze e Lettere, Rendiconti, vol. xii. fasc. x.—We note here the following:—Researches on the electric conductivity of carbon (continued), by Prof. Ferrini.—On a surface of capillarity, by Dr. Poloni.—Influence of climate and soil on the combustibility of tobaccos, by S. Cantoni.

Journal de Physique, June.—Spectroscope for observation of ultra-violet radiations, by M. Cornu.—Spectrometric measurement of high temperatures, by M. Crova.—Magnetic rotatory power of gases, by M. H. Becquerel.—Magnetic rotatory power of liquids and their vapours, by M. Bichat.

SOCIETIES AND ACADEMIES

LONDON

Royal Society, June 19.—"Researches in Chemical Equivalence. Part III.—Nickelous and Cobaltous Sulphates." By Edmund J. Mills, D.Sc., F.R.S., and J. J. Smith.

Although the chemistry of nickel and cobalt is interesting from many points of view, it is more especially attractive from the probable isomerism of these metals. Their combining proportions, in fact, according to the most valuable evidence we possess, appear to be entirely the same. The authors, therefore,

thought it very advisable to inquire on what terms these metals might prove to be mutually equivalent: and the particular equivalence they have examined has been equivalent precipitability of the sulphates, by sodic hydrate, from an aqueous solution.

After describing the mode of preparation of the pure sulphates, the authors give an experimental criticism of the methods of separating nickel from cobalt, finally adopting the one devised by Gibbs. Having then fixed on the method of separation, 1 per cent. solutions of nickelous and cobaltous sulphates were prepared, and a solution of sodic hydrate, of which 10 cub. centims. were capable of precipitating ·8248 grm. of nickelous or cobaltous sulphate. This sodic hydrate was made from sodium, and kept in glass bottles coated internally with a thick layer of paraffin.

A series of nine experiments was made, in which the relative weights of nickelous or cobaltous sulphate present, varied from ·1 to ·9 grm.; the total weight of nickelous and cobaltous salt, and the volume of the solution being, however, always the same, viz., 1 grm. and 100 cub. centims. The experiments were conducted as follows:—The bottles containing the solutions of the sulphates and the sodic hydrate were immersed in a trough into which there was a constant flow of water to bring them to a constant temperature. The necessary quantities of nickelous and cobaltous solutions were then carefully measured out, mixed, and the temperature observed. 10 cub. centims. of sodic hydrate was then added, the solution stirred vigorously, and the temperature again observed. The precipitate was then filtered off as quickly as possible (an aspirator being used to facilitate the filtration), and washed, first with cold and then with hot water. It contained sodic sulphate, cobaltous sulphate and hydrate, and nickelous hydrate, all of which were analytically determined.

If n represent a weight of nickelous sulphate taken, and ν be the hydrate (calculated to sulphate) obtained from it through precipitation, the experiments show that $n = (1 + \cdot 21940\, n)\, \nu$. Similarly, for cobalt, $c = 1 \cdot 1845 y$. The authors give the following conclusions as the result of a discussion of their work:—(1) *The precipitability of nickelous sulphate is directly proportional to its mass*; (2) *The precipitability of cobaltous sulphate is an invariable quantity*; (3) *For an equal weight nickelous and cobaltous sulphates are equally precipitable; the attraction of the one towards the reagent being then inverse to that of the other.*

They accordingly write $\phi\,(NiSO_4) = (\phi\, CoSo_4)^{-1}$.

"On the Formation of Hydrocyanic Acid in the Electric Arc." By James Dewar, M.A., F.R.S., Professor of Chemistry to the Royal Institution.

The inference drawn from experiments given in the paper is that the reaction is in all probability the result of acetylene reacting with free nitrogen, as when induction sparks are passed through the mixed gases, viz.—

$$C_2H_2 + N_2 = 2HCN,$$

and that the hydrogen is obtained from the decomposition of aqueous vapour, and the combined hydrogen in the carbons. It is possible, traces of alkaline salts in the carbon poles may favour the formation of hydrocyanic acid, but, as all attempts to purify the poles so as to stop the reaction failed, I am inclined to believe it is a direct synthesis. The acetylene reaction is one of the many remarkable syntheses discovered by Prof. Berthelot of Paris. The presence of sulphuretted hydrogen is doubtless due to the reduction of the sulphates, invariably present in the ash of the carbon.

"An Account of Experiments on the Influence of Colloids upon Crystalline Form, and on Movements observed in Mixtures of Colloids with Crystalloids." By William M. Ord, M.D. Lond., F.L.S. Communicated by J. Simon, C.B., D.C.L., F.R.S.

Chemical Society, June 19.—Dr. Roscoe in the chair.—The following papers were read:—On Gardenin, by Dr. Stenhouse and Mr. C. E. Groves. This substance has been extracted from "Dekamali gum," the resin of the *Gardenia lucida*. Gardenin by treatment with nitric acid is converted into a mass of red crystals of gardenic acid; an acetyl derivative has been obtained. Gardenic acid in contact with sulphurous acid is converted into hydrogardenic acid.—On dry copper-zinc couples and analogous agents, by Dr. J. H. Gladstone and Mr. A. Tribe. By heating nine parts of coarse zinc filings with one part of finely divided copper in a flask over a Bunsen flame until the filings begin to lose their shape, dark grey granular masses are obtained. These masses constitute the dry copper-zinc couple, which is found to equal in activity the well-known moist copper-zinc couple, prepared by immersing zinc foil in copper sulphate solution; ten grammes of the dry couple convert 5 cc. of ethyl-iodide into zinc ethiodide in about six minutes. Couples of other metals were tried, but none were found to be in practice superior to that formed of copper and zinc.—On the action of sulphuric acid on the hydrocarbons of the formula $C_{10}H_{16}$, by Drs. Armstrong and Tilden. The authors deny the statement made by Ribau that the product of the above action yields a distillate when steam is passed through it consisting of cymene with a liquid isomeride of terpene; the so-called terebene is really inactive camphene, melting at 47°. The crude colophene remaining after the distillation in steam yields on distillation 10–30 per cent. of volatile substances—inactive camphene, terpilene, a paraffin-like body, an optically inactive camphor, &c. — Researches on the terpenes, camphor, and allied compounds, by Dr. Armstrong. Part I. On hydrocarbons associated with the terpenes, and on the formation of cymene from terpenes and allied compounds. II. On the action of iodine on terpenes. III. Camphor derivatives. —Contributions to the history of starch and its transformations, by Messrs. H. F. Brown and Heron. The authors have examined in a most elaborate manner the action of malt extract at various temperatures and under varied conditions, on potato starch. — On the determination of nitric acid by means of indigo, with especial reference to water analysis, by Mr. R. Warington. The author gives the results of much experience with this process, which has the advantages of great simplicity, speed, and delicacy; the results are, however, conditioned by many circumstances which must be known before the method can be applied with delicacy.—Notes on the purple of the ancients, by Dr. E. Schunck. The author has worked up about 400 specimens of *Purpura lapillus*, a shell-fish found at Hastings, and extracted the cyst containing the yellowish secretion which in sunlight becomes purple and forms a permanent dye stuff. The colouring matter apparently belongs to an unknown member of the indigo-blue group.—On the heat of formation of aniline, picoline, toluidine, lutidine, pyridine, dipicoline, pyrrol, glycerine, furfurol, by W. Ramsay.—On ethylenic chlorosulphocyanide and its oxidation into ethylenic chlorosulphonic acid, by J. W. James.—On mixing and heating potassium sulphocyanide with alcohol and chlorobromide of ethylene, potassium bromide, and chlorosulphocyanide of ethylene were obtained. The latter with nitric acid gave chlorocthylene sulphonic acid, the silver salt of which heated with ammonia furnished taurin.—On the boiling points of certain metals and metallic salts, by Dr. T. Carnelly and Dr. W. Carleton Williams.

Linnean Society, June 19.—Prof. Allman, F.R.S., president, in the chair.—Attention was called to two volumes folio on the British fresh water fishes by the Rev. W. Houghton. These, recently issued, illustrate in colours all the known and new species.—The Secretary read a paper on a remarkable branched *Syllis* from the *Challenger* expedition, by Dr. W. C. McIntosh. This Polychæte worm *S. ramosa* was got in the basal canals of a hexactinellid sponge, dredged near Zebu, Philippines. Thread-like in thickness, the branches are intricately arranged among the meshes of the sponge, and it appears that but one head must serve for many branches. Buds and secondary buds are very numerous on the latter, and in a free female pedal bristle-tufts were observed. A fragment of a different form is suggested, as possibly the male of the foregoing rare example of a truly branched annelid, differing in most particulars from anything heretofore recorded.—There followed remarks on *Carpesium* (*C. cernuum*) as indigenous to Australia, by F. M. Bailey. The author supports Mr. Bernay's view of this plant not being introduced, but undoubtedly endemic.—Mr. A. Hammond read a paper on the thorax of the blowfly. Most authorities at present recognise the great preponderance of the mesothorax over the other two segments, but do not fix the limits of each. The author refers to the integumentary parts entering into the thorax of insects, as enumerated by Audouin, and also especially to the views held by Westwood, Burmeister, Lowne, and others. Afterwards he gives a full description of his own dissections and preparations, and reasons for dissent from the majority of workers, though with evident inclination to Audouin's opinions. He concludes that, from the analogy presented by other insects, from the evidence derivable from the phenomena of developmental change, and from a study and consideration of the nervous and muscular systems all combine to show that the thorax of the Diptera, as illustrated in the blowfly, is almost exclusively mesothoracic, a conviction quite at

variance with that promulgated by Lowne in his researches on the blowfly.—The Rev. J. M. Crombie gave an enumeration of the lichens in the herbarium of the late Rob. Brown in the British Museum. These were collected 1802-5 during the notable voyage of Capt. Flinders to New Holland and Tasmania. No complete catalogue of these lichens was published by Brown, though many bear his MS. names, and only the more common species were indicated in the Appendix to the above voyage. A paucity of "saxicole" species in this as in more recent collections of exotic lichens is to be regretted.—Mr. G. Busk read a paper on recent species of Heteropora, founded chiefly on material got in the *Challenger* Expedition. Hitherto material for a knowledge of these has been among fossil forms, but quite lately Mr. Waters has drawn attention to a recent example in the British Museum, said to be from Japan. Mr. Busk now considerably adds to our information on the living types, and enters into several structural peculiarities observed by him.—The abstract of a contribution to the flora of Northern China, by Messrs. J. G. Baker and S. Le M. Moore was read. Some 600 specimens now deposited in the Kew herbarium, and collected by Mr. John Ross in the province of Selim King 40° to 42° N. lat. of the Celestial Empire, furnish the basis of this botanical contribution. Though many species among these are already known, yet the discovery of such forms as *Exochorda serratifolia*, an addition to a genus that has for years remained monotypic—*Saxifraga Rossii*, *Brachylites paridiformis*, and *Betula exaltata*—along with several altogether new species, render the collection valuable. These form a good adjunct to the researches on this relatively unfrequented region; but a knowledge of which is rapidly being accumulated, chiefly through the labours of Maximowicz, Hance, and Franchet.—The Rev. J. M. Crombie briefly indicated the substance of a reply by him to Dr. Stirton's remarks on his paper on the *Challenger* lichens.—Then followed a paper by Pastor H. D. J. Wallengren (of Sweden), on the species of Caddis flies (*Phryganea*) described by Linnæus in his "Fauna Suecia," with notes on, and communicated, by Mr. R. McLachlan. In this communication some twenty-five species undergo a critical revision and determination as identified from the living insects and Swedish entomological collections. Mr. McLachlan, however, does not concur with all the Pastor's conclusions.—On the Bell Bird, by Dr. J. Murie, was a paper taken as read.—Mr. Chas. Holme (Bradford) was elected a Fellow of the Society.

Paris

Academy of Sciences, June 23.—M. Daubrée in the chair.—The following papers were read:—On the absorption, by the atmosphere, of ultra-violet radiations, by M. Cornu. That the solar spectrum extends beyond what the most favourable observations present of it, seems probable from its almost sudden termination on the most refrangible side (in photographs), and the results of comparing this spectrum with that of iron vapour in the electric arc. The atmospheric absorption of ultra-violet radiations is demonstrated by introducing a tube 4 m. long, closed at the ends with fluor spar, between the collimator and the prism of a spectroscope. When the tube is full of air, line 32 of the aluminium spectrum (from electrodes of that metal transmitting the induction-spark) is invisible; but as vacuum is gradually produced, the line appears.—Remarks on a note of Admiral Mouchez, by M. Faye. He argues against the watchmakers being called on to determine experimentally the thermometric correction of the instruments they supply to merchant vessels. These vessels should have the same advantages as the navy in this respect.—Action of so-called poisons of the heart on the snail (*Helix pomatia*), by M. Vulpian. Alcoholic extract of onaye (*Strophantus hispidus*, D.C.), was taken as type of poisons stopping the heart with the ventricle in systole; *muscarine*, with the heart in diastole. The action in both cases was similar to that in frogs. The antagonism observed in mammalia between the effects of muscarine and those of sulphate of atropine, was also observed in snails. The hearts of crustaceans were not, apparently, affected by the two typical poisons named.—On an arithmetical property of a certain series of whole numbers, by Prof. Sylvester.—Inexact application of a theorem of dynamics, by MM. Bertin and Garbe, to explain the motion of the vanes of a radiometer. He disputes the assertion that the motion is produced solely by gaseous matters within the globe (the inference drawn by the authors named from a dynamical theorem). Considering the cause of motion complex, he suggests experiment in the direction of varying the substance and surfaces of the vanes with special regard to the calorific and luminous properties of the materials used; altering the luminous rays especially by polarising them in different directions relatively to the vanes; suspending the globe on two very fine points and inclosing it in a receiver exhausted of air.—On the means of working automatically the upper tube of the economising apparatus constructed at the sluice of Aubois, by M. de Caligny.—On the interoceanic maritime canal, by M. de Lesseps. Some preparatory operations are mentioned. Dr. Companyo, of Perpignan, who directed an important sanitary service in the Suez Canal works, has been sent to Panama to study the best means of preserving the health of workmen; and agents and correspondents have been charged to enlist the most suitable workmen in America.—M. Lissajous was elected Correspondent in Physics, in room of the late Dr. von Mayer.—Map of the solar spectrum, by M. Thollon. This new map, made with the aid of his powerful spectroscope in Italy, is 10 metres long, and contains about 4,000 lines (Ångström's contained 1,600 in a length of 3 metres). M. Thollon remarks on the singular resemblance of the groups A and B, and gives a four-fold classification of solar lines, viz.: 1. Nebulosity without nucleus. 2. Nucleus without nebulosity. 3. Nebulosity predominating. 4. Nucleus predominating. He describes the instruments with which he operated.—On the reappearance of phylloxera in vineyards subjected to insecticide operations, by M. Marion.—On the positions of the Comet Tempel II., 1867, deduced from four first observations at the observatory of Rio de Janeiro, by M. Cruls.—Resolution of systems of linear congruences, by M. Demeczky de Gyergyoszentmiklos.—Addition to a previous note on the series of Laplace, by M. de Saint Germain.—Study of the molecular constitution of liquids by means of their coefficient of expansion, their specific heat, and their atomic weight, by M. Pictet.—Explanation of the bolide at Geneva on June 7, 1879, by M. Oltramare. He considers such a phenomenon arises from electricity detaching a portion of the electrified cloud.—Study on alloys of lead and antimony and especially on the liquations and supersaturations they present, by M. De Jussieu.—On the production of hydrocellulose, by M. Girard. He gives three methods of producing it.—On the retrogradation of superphosphates, by M. Joulie.—On the respiratory apparatus of Ampullaria, by M. Sabatier.—Experimental researches on the therapeutic value of intravenous injections of milk, by MM. Bechamp and Baltus. The transfusion of milk within certain quantitative limits (comparatively extended) is harmless in the dog, but has too little therapeutical value to be substituted for transfusion of blood.—On the total absence of amnios in the embryos of the hen, by M. Dareste.—Prof. Draper presented a photograph of the solar spectrum and that of oxygen.

CLEMENTS' ORGANIC CHEMISTRY

A Manual of Organic Chemistry, Practical and Theoretical, for Colleges and Schools, Medical and Civil Service Examinations, and especially for Elementary, Advanced, and Honours Students at the Classes of the Science and Art Department, South Kensington. By Hugh Clements, of H.M. Civil Service. (Blackie and Son, 1879.)

A GOOD text-book should be correct as to facts and descriptions, so as to leave nothing for the student to unlearn; it should, without being tedious or cumbrous, be minute as to the information it contains, so as to spare the student the necessity of going over the same ground again; its arrangement should be thoroughly logical, building up the science from its first principles, and presenting it to the reader as a connected whole and not as a collection of dislocated and dissevered members; its language should be lucid, terse, and vigorous, in order to relieve the intellect and memory from any unnecessary strain; and, finally, it should be written by a person who not only knows the subject, but knows also how to teach it.

It is greatly to be feared that the encouragement offered by the Science and Art Department to the teaching of the various sciences included in its syllabus has not been productive of unalloyed good; it has called into existence a vast number of presuming and incompetent "science (so-called) teachers," and has undoubtedly been the ultimate cause of the deluge of illogical, incorrect, and imperfect text-books that has for years past flooded the educational market. These worthless and pernicious books naturally divide themselves into two classes, and it is very hard to tell which class is the more mischievous. In the first class we have the books that carry on their very faces conclusive evidence that they are written by individuals who know little or nothing of the subject they are pretending to treat—by men who have an enormous amount to learn before they can have anything whatever to teach. When these *savants* condescend to treat of experimental science, it becomes at once evident that they are writing about experiments they have never performed and apparatus they have never seen.

In the second class we have abler, but certainly not better books—these are the books written by fairly erudite authors, but written with a motive that is a disgrace to the author, an insult to the teacher, and a monstrous injustice to the student—they are the barefaced *cram books*—books written in order to enable the student to pass a specified examination, and not to aid him in obtaining any real knowledge of the subject. We are truly sorry to find that these miserable volumes are very extensively patronised and adopted by teachers, and if we are to judge from recent articles and speeches cramming and "spotting the questions" are considered not only legitimate but praiseworthy proceedings. For the credit of the teaching profession we are happy to say that there are many honest and able teachers with whom a correct and thorough knowledge of the subject is the first consideration, and a "pass" but a subordinate one; yet it must be confessed that an alarming number of teachers seem to think that "science teaching" consists in imparting to their students a few leading facts without any attempt at showing their connection or their bearing upon one another, and in getting them to learn, by *rote*, stereotyped answers to a few stock questions, trusting to chance that in one shape or another a sufficient number of these *stock questions* will turn up to enable their pupils to obtain at least 33 per cent. of attainable marks, and so entitle them to a "second class." Other teachers, considerably more able, but scarcely more conscientious, study the hobbies and the idiosyncracies of the examiners, and in the course of several years' practice manage to attain a wonderful amount of skill and success in securing passes. On the strength of this success they gain a pretty wide reputation as "excellent teachers," while in reality they impart to their pupils little or no knowledge of their subject as a science; all the information is conveyed and accepted on the mere *ipse dixit* of the teacher without any attempt at logical demonstration, and as a natural result teacher and taught get thoroughly imbued with a most pernicious dogmatism, which must be entirely eradicated before either becomes susceptible of any true scientific education. Much of the so-called science teaching has exactly the opposite effect to what the Science and Art Department intended it to have, and the money granted year by year has mostly gone to the pockets of successful crammers, while the honest painstaking teachers have had but a meagre share of the coveted loaves and fishes and a still more meagre share of fame.

Had Mr. Clements's volume been a solitary instance it would not have merited even a passing notice, but when we remember that it is only a specimen, and probably not the worst, of a rapidly-increasing class, we feel that as a representative of that class it deserves a fair and serious consideration. As some of the essentials of a good text-book, we have enumerated correctness and completeness as to facts and descriptions; when an author describes any process he should do it correctly and with sufficient minuteness to enable the student to comprehend every step of it, and, if he possesses the requisite apparatus, to go through it himself without further aid or direction. We shall quote from the book before us a few paragraphs relating to some of the simpler processes of organic chemistry, and let the reader judge how much assistance a student can derive from them. On pp. 3–13 the author gives directions how to perform "combustions" and the quantitative analysis of organic compounds generally. The engraving of the potash bulbs in Fig. 1, p. 4, is certainly misleading, and no one, either from the engraving or the accompanying explanation, could ever find out how the CO_2 finds its way to the bulbs *p*; if it was necessary to put in an engraving and a description of it at all, it was certainly quite as necessary that both should be correct and intelligible; at present they are neither. In his description of the method of determining the C and H in an organic compound, the author has hopelessly mixed up two distinct processes, viz., combustion in a closed tube and combustion in a current of air or oxygen. The tube in the engraving is represented as closed at one end, and there is no reference whatever to a tube open at both ends; consequently we fear that many students would attempt to introduce the platinum boat from the right-hand end of the tube. It may be said that their common

sense ought to show them otherwise; but when the author has had some years' practical experience, he will undoubtedly acknowledge that in scientific experiments very little reliance is to be placed on the common sense of beginners. The author says:—

"About one-fourth of the combustion tube is filled with copper oxide, the sugar weighed in a little glass tube, and shaken into the combustion tube and thoroughly mixed with the oxide by raking them together by a wire. The remainder of the tube is filled with oxide; or the sugar may be put in a platinum boat that will pass into the tube."

As an alternative, for *what* may the sugar be put in a platinum boat? It appears from the text that the boat is to be employed instead of filling up the "remainder of the tube with oxide." No further reference is made to the method of determining the C and H in organic compounds except on p. 11, where we are told that in the presence of nitrogenous substances the products of combustion must be passed over heated metallic copper, and we have failed to find a single hint to enable the student to determine the C and H in the presence of Cl, Br, I, S, or alkaline metals. All the processes given in the book, *supposing them to be intelligible to a beginner*, are utterly inadequate.

Referring to the determination of nitrogen, the author states (p. 12):—

"The ammonia process answers, except in cases where the nitrogen occurs in the form of nitric acid or cyanogen, when this element must be estimated by volume. This method is applicable in all cases. A combustion tube of about 32 inches long is taken, rounded like a test tube at one end. This tube is filled with some carbonate that, when heated, will give off carbonic anhydride, such as manganous carbonate, magnesite or hydric sodic-carbonate, and some mercuric oxide. A weighed portion of the substance for analysis, with upwards of forty times its weight of a mixture of oxide of copper and mercury, the rinsings of the mortar, a plug of asbestos, then about 4 inches of cupric oxide, asbestos and a layer of about 8 inches of metallic copper. The end of the combustion tube is drawn out and connected with a bent delivery tube, dipping beneath the mercury in the trough. When all is ready the carbonate in the tube is heated to generate a current of carbonic anhydride to drive out all the air.

"The metallic copper and copper oxide are heated simultaneously, and when the escaping gas is free from air, insert the end of the delivery tube through the tubulure of the vessel," &c., &c.

We suppose that Mr. Clements would barely maintain that the N occurs as *nitric* acid in nitromethane or any of its analogous compounds; but we should be very much surprised if he or any one else could make a correct determination of the nitrogen in those compounds by his ammonia method; and would it surprise him to learn that when N occurs as a component of cyanogen it may be correctly estimated by the ammonia method? What is the meaning of the remainder of the preceding extract? Having *filled* the tube with "some carbonate" and mercuric oxide, what is the student to do with the Benjamin's mess, the ingredients of which are enumerated in the next sentence, if a heap of words without a single predicate can be called a sentence? Without doubt the author meant a mixture of cupric and mercuric oxides by "a mixture of the oxide of copper and mercury," but a beginner, we should unhesitatingly say, would mix metallic mercury with oxide of copper if he had no other guide than this book. Then what mortar, trough, tubulure, and vessel are referred to? Where are they to come from, and what are they used for? A chemist may guess what is meant, but heaven help the beginner who tries to make his first nitrogen determination with the sole aid of this new light. We cannot believe it possible for a man who had ever "done a combustion" to have penned these pages 3-13.

We have neither space nor patience for further extracts from the author's description of processes and apparatus, but we would ask the reader to refer to pp. 164 and 165, where Messrs. Frankland and Ward's gas apparatus is described, and after he has read it let him try to find out how it was possible for a person who had ever seen the apparatus to write that description? or even if he had never seen it, how could he ignore the simplest principles of physics and propose to drive the gas from A by simply elevating M? The drawings and explanation are wofully incomplete and misleading.

It is needless to point out all the errors of the author, but there is one class we cannot help referring to, as it gives us a fair test of the extent of the author's knowledge of his subject. To translate constitutional to graphic formulæ is considered a very elementary exercise, but in this our author fails miserably; thus he gives (p. 219):—

$$\text{“ Succinic Acid}\left\{\begin{array}{l}\mathrm{COHo}\\ \mathrm{CH_2}\\ \mathrm{CH_2}\\ \mathrm{COHo}\end{array}\right. \qquad \begin{array}{ccccccccccc} & & & & \mathrm{H} & & \mathrm{H} & & & & \\ & & & & | & & | & & & & \\ \mathrm{H} & — & \mathrm{O} & — & \mathrm{C} & —— & \mathrm{C} & — & \mathrm{O} & — & \mathrm{H}\text{”} \\ & & & & | & & | & & & & \\ \mathrm{H} & — & \mathrm{O} & — & \mathrm{C} & & \mathrm{C} & — & \mathrm{O} & — & \mathrm{H} \end{array}$$

where the two lower atoms of C are represented as bivalent. On the same page he gives—

$$\text{“ Tartaric Acid}\left\{\begin{array}{l}\mathrm{COHo}\\ \mathrm{CHHo}\\ \mathrm{CHHo}\\ \mathrm{COHo}\end{array}\right. \qquad \begin{array}{ccccccccccccc} & & & & \mathrm{H} & & & & \mathrm{H} & & & & \\ & & & & | & & & & | & & & & \\ \mathrm{H} & — & \mathrm{O} & — & \mathrm{C} & — & \mathrm{O} & — & \mathrm{C} & — & \mathrm{O} & — & \mathrm{H}\text{”} \\ & & & & | & & & & | & & & & \\ \mathrm{H} & — & \mathrm{O} & — & \mathrm{C} & — & \mathrm{O} & — & \mathrm{C} & — & \mathrm{O} & — & \mathrm{H} \end{array}$$

where, as in the preceding, we have no oxatyl group in the graphic formula, although we have two such in each of the constitutional. Again, on p. 225 we have—

$$\text{“ Lactic Acid}\left\{\begin{array}{l}\mathrm{CMeHHo}\\ \mathrm{COHo}\end{array}\right. \qquad \begin{array}{ccccccccccccc} & & & & & & \mathrm{H} & & \mathrm{H} & & & & \\ & & & & & & | & & | & & & & \\ \mathrm{H} & — & \mathrm{O} & — & \mathrm{C} & — & \mathrm{C} & — & \mathrm{C} & — & \mathrm{O} & — & \mathrm{H.}\text{”} \\ & & & & \| & & | & & | & & & & \\ & & & & \mathrm{O} & & \mathrm{H} & & \mathrm{H} & & & & \end{array}$$

$$\text{“ Mercuric Ethide, HgEt}_2 \quad \begin{array}{ccccccccccccc} & & \mathrm{H} & & \mathrm{H} & & \mathrm{H} & & \mathrm{H} & & & & \\ & & | & & | & & | & & | & & & & \\ \mathrm{H} & — & \mathrm{C} & — & \mathrm{C} & — & \mathrm{C} & — & \mathrm{C} & — & \mathrm{Hg} & — & \mathrm{H.}\text{”} \\ & & | & & | & & | & & | & & & & \\ & & \mathrm{H} & & \mathrm{H} & & \mathrm{H} & & \mathrm{H} & & & & \end{array}$$

Where is the group Me in the first and the two groups of Et in the second? But to crown all he has begun this glorious page thus—

$$\text{“ Methylic Ether, }\left.\begin{array}{l}\mathrm{CH_3}\\ \mathrm{CH_3}\end{array}\right\}\mathrm{O} \qquad \begin{array}{ccccccccc} & & \mathrm{H} & & \mathrm{H} & & & & \\ & & | & & | & & & & \\ \mathrm{H} & — & \mathrm{C} & — & \mathrm{C} & — & \mathrm{O} & — & \mathrm{H.}\text{”} \\ & & | & & | & & & & \\ & & \mathrm{H} & & \mathrm{H} & & & & \end{array}$$

Is it possible that he does not know that this is the graphic formula of ethylic alcohol, EtHo, a very different compound indeed from $\mathrm{Me_2O}$? We will not multiply instances, though we might very easily do so;

but we cannot resist the temptation to cull the two following gems :—

P. 228—
"Boric Methide, $B(CH_3)_3$ 
P. 234—
"Allylamine, $N(C_3H_5)H_2$ 
It is a great pity the author ever meddled with graphic formulæ—he may have some very original notions about the constitution of organic bodies, but for his own credit he ought to have made his constitutional and graphic formulæ agree. The only thing we ever saw at all approaching the preceding in ridiculous incongruity was the following, handed to us by a beginner :—

Ammonic Nitrate, $NO_2(NH_4O)$ 
We kept this as a curiosity, little dreaming that we should ever live to see it surpassed in a text-book.

In no instance can we say that the information is complete and satisfactory, while in very many cases it is decidedly misleading. We fear that very few of the *model* answers to the questions of the Science and Art Department would have been marked "*excellent*" or even "*good*" by the examiners. For instance—

"30. How can you detect the presence of nitrogen in an organic substance?
Ans. "See the estimation of nitrogen."

We have looked again and again through the pages referred to, and certainly there is nothing there about the detection of nitrogen; does the author know any difference between detection and estimation?

"35. If an alkaline solution of potassic cyanide be boiled what decomposition takes place?
"The formiate of potassium is formed and ammonia thus—$KCN + 2H_2O = KCOHo + NH_3$."

This answer is brief, if not to the point, but what on earth is *KCOHo?*

"74. How would you separate alcohol from acetic acid?
"Acetic acid freezes at 17° C. or under, while alcohol remains liquid at much lower temperatures."

Very simple, but has the author ever tried it?

"99. What chemical changes ensue when a mixture of ethylic iodide and zinc are heated to 150° C. in a sealed tube?
"$2EtI + Zn = ZnI + 2C_2H_5$."

Is that all? We fancied hitherto that the merest tyro in chemistry knew better. We have neither space nor inclination to give further specimens of these answers, but let the reader refer to Nos. 100, 101, 102, &c., and judge for himself if the answers are satisfactory.

If we look at the arrangement of the book we must admit that we can find no sequence or logical connection between one part and another. Terms are employed before being properly defined, and often without being defined at all. We most sincerely pity the students who may attempt to learn organic chemistry by following the order of this book without having many a missing link supplied. Under the head "Alcohols" we have three mentioned—Methylic, Ethylic, and Phenylic; and by referring back to the "Theory of Compound Organic Radicals," we find mention made of several others, but no scientific arrangement in series and no general methods for the synthesis or preparation otherwise of the various terms of each series. The same objection applies more or less to the treatment of the ethers, aldehydes, acids, and anhydrides. By the way, we have not often seen carbamide or urea called a diamine, nor ethylic butyrate, C_3H_7COEtO called "*butylic* ether;" that term is generally reserved for $\left.\begin{matrix}C_4H_9\\C_4H_9\end{matrix}\right\}O$.

There are several pages giving nothing but the names and formulæ of compounds without any attempt to give their properties, their connection with one another, or the methods of preparing them; a few are referred to in other parts of the book, but necessarily they come before us then as isolated units and not as closely allied members of a consecutive series.

As to the language we need say but little. It is generally awkward or ambiguous, and often incorrect. The way pronouns and conjunctions are employed is sometimes alarming; in one paragraph of very moderate length we have the little word *or* occurring at least nineteen times, until we begin to think that the author has been taking the Apostle Paul for his model. In other places the pronoun *it* keeps dancing before our face like some imp, peering out of the most unexpected nooks and corners. Here is a model sentence—"A subsidence of temperature and an almost total absence of precipitated iodine after a few drops of the liquid remaining in the flask is boiled with HNO_3." What *is* boiled? is it the subsidence of temperature?

We have by no means pointed out the worst errors—we have purposely confined our remarks to the most elementary, and we think the reader will now be able to answer for himself whether the present author "knows his subject and knows how to teach it," or not.

One extract more and we have done with the book and its author, who says on p. 61 :—"Nitrous oxide and carbonic anhydride are other anæsthetics." Well, so they are, and we could only wish some people had the toothache "awful" and had the latter anæsthetic administered to alleviate their pain, and *ours*.

As we have said before, we have reviewed this book as a sample—and not the worst—of an ever-increasing class of publications, and we would ask teachers is it any wonder that "science teaching" has in many instances become a byeword and a reproach? Can we expect any different result until all sham-books and cram-books are consigned to the oblivion they so richly deserve?

E. H.

EUCLID AND HIS MODERN RIVALS

Euclid and His Modern Rivals. By Charles L. Dodgson, M.A. (London: Macmillan, 1879.)

Elementary Geometry. Books i.—iv., containing the subjects of Euclid's first six books; following the syllabus of geometry prepared by the Geometrical Association. By J. M. Wilson, M.A. Fourth edition. (London: Macmillan, 1878.)

BY a curious chance these two works reached our hands nearly on the same day, and as Mr. Dodgson devotes a great portion of his space (62 pp.) to the consideration of Mr. Wilson's Geometries, we have thought it well to notice the two authors at the same time. As however it is patent from the fact of Mr. Wilson's work having reached a fourth edition, that his method is not unknown to, and, may we add, not unappreciated by, a large section of mathematical teachers, we shall at once pass on to a consideration of Mr. Dodgson's book, only noticing Mr. Wilson's book in connection with the criticisms put forward in "Euclid and His Modern Rivals."

A few words by way of introduction. Mr. Dodgson has been a teacher of geometry at Oxford, we believe, for nearly five-and-twenty years, and during that time has had frequent occasion to examine candidates in that subject. For a great part of the above-stated period things went pretty smoothly, and King Euclid held undisputed sway in the "Schools;" but eleven years ago a troubler of the geometrical Israel came upon the scene, and read a paper before the Mathematical Society, entitled "Euclid as a Text-Book of Elementary Geometry." The agitation thus commenced acquired strength, and at length, in consequence of a correspondence carried on in these columns, the Geometrical Association was formed. A prime mover in this matter was that Mr. Wilson who wrote the paper, and subsequently brought out the geometry cited. Mr. Dodgson is one of the gentlemen opposed to this change, and the moving cause of the present Iliad is the "vindication of Euclid's masterpiece." Another consequence of the agitation is that many have tried their prentice hands on the production of new geometries—"rivals," our author calls them—"forty-five were left in my rooms to-day." Can we wonder then, that, his soul being stirred within him, he should overhaul a selection of them to see what blots he could "spot" in them? He might well have taken for his motto one once familiar to us—

> "If there's a hole in a' your coats,
> I rede ye tent it;
> A chiel's amang ye takin' notes,
> An' faith he'll prent it!"

Our author's criticism takes a peculiar form, but we shall not blame him for this, for he has afforded us much amusement, and we quite hold with the Horatian line he cites in extenuation of his mode of procedure: "Ridentem dicere verum quid vetat?" We believe he has made a good many hits, but at times his wit, we think, has led him too far. We shall not, however, here give any account of his plot—we prefer to refer our readers to the work itself—but confine our notice to the remarks upon Mr. Wilson's books, and upon Mr. Morell's "Euclid Simplified." [1]

Mr. Dodgson devotes forty-eight pages to Mr. Wilson's "Elementary Geometry" (second edition, 1869). We can hardly see why so much space should be devoted to a work which seems tacitly to have been withdrawn by the author, or, at any rate, to have been considered inferior to the work under review. Is it that the "scene" was written some time since, and was considered to be too good to be sacrificed? Happily it is not our business to defend Mr. Wilson's views on "direction;" he is perfectly competent to defend his own views, and no doubt, should he see fit, will do so at the right time.

"Minos"—who argues for Mr. Dodgson—himself seems to think that his remarks will now and again be considered hypercritical. Take the following:—

Niemand (the general representative of the "rivals," quoting from the "Elementary Geometry"). Two straight lines that meet one another form an angle at the point where they meet (p. 5). *Min.* Do you mean that they form it "*at* the point," and nowhere else? *Nie.* I suppose so. *Min.* I fear you allow your angle no magnitude, if you limit its existence to so small a locality! *Nie.* Well, we *don't* mean "nowhere else." *Min.* (*meditatively*). You mean *at* the point—and *some*where else? *Where* else, if you please? *Nie.* We mean—we don't quite know why we put in the words at all. Let us say "Two straight lines that meet one another form an angle." *Min.* Very well. It hardly tells us what an angle *is*, and, so far, it is inferior to Euclid's definition; but it may pass. Again (p. 73), *Nie.* reads, P. 5, Ax. 5, "Angles are equal when they could be placed on one another so that their vertices would coincide in position, and their arms in direction." *Min.* "Placed on one another!" Did you ever see the child's game, where a pile of four hands is made on the table, and each player tries to have a hand at the top of the pile? *Nie.* I know the game. *Min.* Well, did you ever see both players succeed at once? *Nie.* No. *Min.* Whenever that feat is achieved you may *then* expect to be able to place two angles "on one another!" You have hardly, I think, grasped the physical fact that, when one of two things is *on* the other, the second is *underneath* the first. But perhaps I am hypercritical.

What the text means is, of course, that B, C, D could be placed upon A or A upon B, C, D, so as to coincide. A still more striking instance is p. 160. Mr. Wilson adopts the syllabus-definition, "When one straight line stands upon another straight line and makes the adjacent angles equal, each of the angles is called a *right angle*"—a definition, by the way, remarkably like Euclid's. Minos says, "allow me to present you with a figure, as I see the Syllabus does not supply one—

A Here AB 'stands upon' BC, and makes the
B adjacent angles equal. How do you like these
C 'right angles?'"

This is a hit, of course, indeed a double hit, the one farcical in its illustration, the other sober enough, for the Syllabus considers that two angles (a major, and a minor, conjugate) are formed by two straight lines drawn from a point. Mr. Dodgson is very amusing upon the "straight" angle, and, no doubt, would be equally so upon the equivalent "flat" angle. A good phrase is still a desideratum, but De Morgan long ago pointed out that "the angle made by a straight line with its continuation is a definite angular magnitude," and considered its half to be the best definition of a right angle.

[1] A work we ourselves had occasion very strongly to condemn—see NATURE, vol. xiii. p. 202.

We pass over many passages we had marked, with saying that in many cases the objections are sound but trivial. Objection is taken to Mr. Wilson's remark, "Every theorem may be shown to be a means of indirectly measuring some magnitude," and Niemand abandons "every." We think, however, that Niemand might have made a better fight of it and suggested that what is intended is that, for instance, all the theorems of the first book are directly or indirectly required for the proof of the 47th Proposition, which is surely a proposition concerned with the measurement of magnitude.

On p. 177 Minos says of the exercise, "Show that the angles of an equiangular triangle are equal to two-thirds of a right angle. In this attempt I feel sure I should fail. In early life I was taught to believe them equal to *two right angles*—an antiquated prejudice, no doubt; but it is difficult to eradicate these childish instincts." Mr. Dodgson was taught that the *three* angles were equal to this magnitude; the question says "angles" surely in the plain sense of each angle being equal, &c. Again, in the construction for proposition corresponding to Eucl. i. 9 objection is taken to "finding a radius greater than half *A B*" (it should be *A C*): "it would seem to require the previous bisection of *A B*" (*A C*). Thus the proof involves the fallacy "*Petitio Principii.*" Surely one can take a line greater than or equal to *A C*; where, then, is the fallacy? Exception is taken to the proposition "the area of a trapezium is equal to the area of a rectangle whose base is half the sum of the two parallel sides, and whose altitude is the perpendicular distance between them" as being "a mere 'fancy' proposition of no practical value whatever." We have met with it in works on co-ordinate geometry and elsewhere. Then again the theorem (Apollonius's) on Mr. Wilson's p. 95 is branded "new," "but even with that mighty name to recommend it, I cannot help thinking it rather more curious than useful." It is our own impression that it is one of the most important "riders" from the second book, and if Mr. Dodgson has been teaching geometry for nearly five-and-twenty years, so have we—but we do not confine our teaching to the text-book only, we devote a great part of our geometrical teaching time to the working of exercises.

Our conclusion from the examination of Mr. Dodgson's objections to Mr. Wilson's last book is that the majority of them can be easily met; indeed, many of them are mere verbal quibbles; the rest arise from the very different standpoints taken up by the two writers, and here there is likely to be "war to the knife."

A word or two on Morell's (J. R.) "Euclid Simplified." It is very easy work to pick this little book to pieces, but we cannot understand a statement of Mr. Dodgson's on p. 148. Of the proposition "Every convex closed line *A B C D* enveloped by any other closed line *P Q R S T* is less than it," he says the method used fails, "as of course all methods must, the thing not being capable of proof." We cannot call to mind any English text-book in which the proposition is proved, but there is what we have thought was a proof in Sannia and D'Ovidio's "Elementi di Geometria," p. 32.

We are bound to say that "Euclid and his Modern Rivals" is not all amusing reading. It alternates

"From grave to gay,"

and more than a third part is devoted to appendices, the third to the sixth of which (73 pages) must have cost the author a great deal of thought and labour. We fear, however, it will not get the attention it deserves. It is hard reading, and one has hardly been led up to it by the amusement provided in the four Acts of the Drama. Some little trouble is involved in mastering the symbols and their significance.

The fourth act considers the objections brought by Mr. Wilson ("Euclid as a Text-Book," &c.) and others against the use of Euclid for junior pupils on the score of unsuggestiveness and want of simplicity of style, the exclusion of hypothetical constructions, &c. We need not consider them here, but refer to two articles by the Rev. Dr. Jones ("On the Unsuitableness of Euclid as a Text-Book of Geometry," *Trans.* of Liverpool Lit. and Phil. Society, published in a separate form; and "Review of Mr. Todhunter's Essay on Elementary Geometry," (*Monthly Journal of Education*, 1875, pp. 97-112, 150-160), neither of which is referred to by our author, though he quotes largely in the appendix from Mr. Todhunter's Essay and also from a review of Mr. Wilson's first Geometry in the *Athenæum* for July 18, 1868, written by Prof. De Morgan. We could instance other geometries which have an equal claim to be considered with any of those criticised by Mr. Dodgson, and we should rather have written "Euclid and *some* of his Modern Rivals."

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts. No notice is taken of anonymous communications.*

[*The Editor urgently requests correspondents to keep their letters as short as possible. The pressure on his space is so great that it is impossible otherwise to ensure the appearance even of communications containing interesting and novel facts.*]

The Papau or Papaye

IN NATURE, vol. xix. p. 447, is a paragraph relative to the singular qualities of the *Carica papaya*. I cannot but think that some of the properties attributed to this vegetal in British Guiana by the natives of that colony are exaggerated somewhat, *e.g.*, the tempering of steel by its sap, &c.

Sir Wyville Thomson, in the first volume of "The Voyage of the *Challenger*," gives a capital representation of a group of these papaw-trees in the garden of the Admiral commanding on the North American station at Clarence Hill, Bermudas, where they seem to abound; I do not know if these diœcious plants are indigenous to these islands or introduced from the West Indies and tropical America. From the cut above mentioned can be seen the quaint growth of these paradoxical trees, which must have been esteemed by the early voyagers, as they have been introduced into all parts of the tropics. The singular-looking straight stems (not unlike the gigantesque tree-cabbage stalks of the Channel Islands) are crowned with a tuft of digitate leaves, somewhat at a distance resembling those of the *Aralia papyrifera*, under which the clusters of black purple fruit protrude. In the islands of Bourbon and Mauritius they make a passable *compôte* of these fruit, which are pulpy and full of black seeds when ripe, and the Creole children eat them raw, with what effect on their insides I know not; the birds, however, will not touch them, and as they fall they rot on the ground beneath. In Mauritius, where we lived principally on ration beef cut from the tough flesh of Malagasy oxen, we were in the habit of hanging the ration under the leaves of the tree itself, and if we were in a hurry for a very tender piece of *filet*, our cook would wrap up the undercut of the sirloin in the leaves, when the newly-killed meat would be as tender as if it had been hung for a considerable time. Whence are these deleterious effects causing rapid decomposition of animal fibre? and are there any other trees which possess similar properties?

The Malabars, who were introduced into Mauritius as Coolies, would not sleep under tamarind trees, on account of their supposed noxious effects; but it is possible that superstition has something to do with their objection.

S. P. OLIVER

On the Origin of Certain Granitoid Rocks

DR. CALLAWAY's interesting letter with the above heading in NATURE (vol. xx. p. 219) tempts me to send you the following paragraph from my paper in the *Quart. Journ. Geolog. Soc.* for May, p. 286, in which the hälleflintas of the Arvonian there mentioned are first described:—

"The mode of behaviour of the quartz also here is particularly interesting and instructive in regard to the changes which many crystalline rocks have undergone, especially the gneisses. In some cases the quartz is seen in distinct fragments, but yet coalescing, as if attracted together by some natural affinity from the surrounding material. In the next place the grains are so compressed together (and yet distinctly fragmentary) that all other material is removed, and nests of pure quartz grains only are seen, having a very crystalline appearance. By this selective process also the darker material is brought together and made to fold round the nests, so that a banded or imperfect flow-structure is given to the rock. All this looks as if an incipient gneiss was being formed, the metamorphic action being incomplete, a kind of semi-metamorphism and softening having taken place sufficient only to allow the particles to arrange themselves according to their natural affinities."

It will be seen that the conclusions arrived at by Dr. Callaway in his recent examinations of similar rocks in Shropshire are almost identical with those previously formed by myself in Pembrokeshire. The careful microscopical examination of rocks of an intermediate type like these hälleflintas appear to be, cannot fail, I think, to clear up some of the difficulties hitherto experienced in endeavouring to explain the origin of many of the crystalline rocks.

Hendon, July 4

Distribution of the Black Rat (Mus rattus, Linn.) in Italy

IT may interest the readers of NATURE to know that the black rat is very abundant and widely distributed in Italy and her islands. In the Central Collection of Italian Vertebrata which I have founded in the Florence Zoological Museum, I have a large series of specimens from no less than fifteen localities, viz., Domodossola, Casale, Florence, Radda, Arezzo, Castelfalfi, Lecce on the continent, Bastia (Corsica), Cagliari (Sardinia), Castelbuono Madonie (Sicily), and from the islands of Elba, Pianosa, Montecristo, Giglio, and Lipari. On the smaller islands the larger *M. decumanus* does not exist at all, but elsewhere the two species live side by side. In the Florence Museum we have *M. decumanus* in the cellars, and *M. rattus* upstairs. This proves that the black rat is very far indeed from extinction with us; I should say that it is generally more abundant in Italy than its larger congener, at least such is my experience.

I may add that we have *two*, if not three, very distinct varieties of *M. rattus*, viz., the typical *black M. rattus*, the grey and white *M. tectorum*, Savi, and the brown hirsute *M. alexandrinus*. The two former are positively one species, and I have them from the same litter; the latter is, I believe, generally admitted to be specifically identical with *M. rattus*.

HENRY H. GIGLIOLI

Royal Zoological Museum, Florence, July 4

Barbed Hooklets on Spines of a Brachiopod

MR. THOMAS DAVIDSON, F.R.S., describes, on p. 275, and figures, in pl. xxxiv. of the Supplement to his "Carboniferous Brachiopoda," now on the eve of publication, some important points in the structure of *Spirifera lineata*, Martin, which specimens in my collection have revealed. In this species the shell structure is minutely punctate, and the flattened spines, which are usually broken off short, contain in their interior a double canal, that terminates upon the outer surface of the shell in a series of double pores. I have recently been fortunate enough to find a specimen from the High Blantyre limestone shales having the spines in place. It appears that these spines are provided with numerous marginal opposite hooklets usually pointing towards the free end of the spine. So far as I am aware, this structure is unique amongst the brachiopods. Mr. Davidson has kindly undertaken to note this interesting fact in the explanation of the plates of his forthcoming monograph, the text having been printed off before this observation was made; but I should like to draw the attention of palæontologists to the point, as perhaps similar structures may be found in other brachiopods. The materials are in Mr. Davidson's hands for extended notice when his leisure allows him.

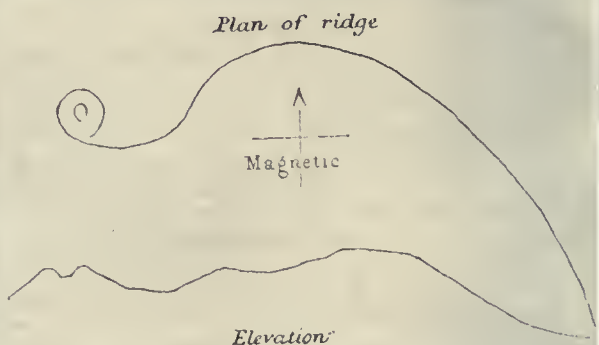
JOHN YOUNG

Hunterian Museum, Glasgow University, June

The Serpent Mound of Lochnell, near Oban

I WALKED over yesterday from here to examine this for myself. I started with some feelings of doubt as to whether it was not one of those fantastic shapes naturally assumed by igneous rocks, seen through the spectacles of an antiquarian enthusiast. I came away quite satisfied that it is an artificial shape, designedly given, and deliberately intended to represent a snake. It partly closes the entrance of a singular little rock amphitheatre with a waterfall at the head (the north end of it), the Loch being to the southward. There is a raised plateau to the northward of the serpent, nearly square. The ground is apparently a rubble of gravel, stones, and dirt, such as is found in moraines. The head of the snake had been opened, and showed a quantity of stones with some indication of a square chamber in the middle.

I do not pretend to any antiquarian knowledge. The impression that it suggested to me, on the spot, was that a party had endeavoured to entrench itself, at the spot, but had been attacked before the entrenchment was complete on more than one face, and that the rampart was then converted into the snake form to commemorate either a successful assault, or the successful defence of an unfinished work.



I inclose you a sketch plan and elevation, of a very rough kind, which I made on the spot and have not retouched since, except by inking over my pencil marks.

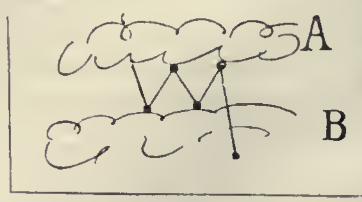
You have already (some years back), given a drawing and description of it. It should be stated that it is at the north-west corner of Lochnell, close alongside of the road from Oban to Callanach.

C. W. M.

Oban, June 19

The Origin of Hail

I SHOULD feel much obliged if any of your readers would kindly explain for me the following "explanation" of the origin of *hail;* which I have come across while reading for an examination:—



"*Hail.*—It consists of concentric layers of ice, and is caused by electricity. Imagine two clouds, A and B, charged with different fluids, and suppose that a drop of water falls from A. Its

fall will be very rapid, both on account of gravitation and attraction, and (*a*) *the evaporation will be so great*, that it will be *frozen*. On touching the cloud B it *condenses* (*b*) *part of its vapour*, gets thus a coating of ice, and, having the same fluid as B, it will be repelled towards A, and so on, downwards and upwards, until it becomes heavy enough to fall to the ground."

My difficulties are the following :—Whence comes the evaporation spoken of at (*a*)?

According to the above, when it reaches B it is frozen. What then am I to understand by the "condensation of part of its vapour (*b*)?"

Also, would not the two clouds, A and B, having opposite fluids, themselves unite?

If you will kindly solve me these difficulties you will greatly oblige an IGNORAMUS

Butterfly Swarms

WITH reference to the case mentioned in NATURE, vol. xx. p. 220, I agree with your correspondent that "local fecundity" cannot be the cause of the great number of *Vanessa cardui* observed this year in the south of England, more especially as this species does not emerge from the chrysalis until the end of July at the earliest. It therefore appears to me probable that the specimens observed have migrated (having hybernated) from the Northern Counties or even from Scotland, in consequence of the exceptional severity of the weather this season. I would also suggest that the "periodical abundance" of this butterfly, as also that of *Colias hyale* and *Edusa*, besides several others, may be caused by some peculiarity in the food-plant itself. This is rendered more likely by the fact that both *Colias hyale* and *Edusa*, which feed upon plants of the Leguminous order, and often of the same species, appear in great abundance at the same period.

I may mention that where I reside I observed many specimens of *Vanessa cardui* last year (1878). In the preceding year (1877) both *Colias hyale* and *Edusa* were exceedingly plentiful, whereas last year (1878) I did not see a single specimen of either of these butterflies. F. H. HAINES

The Buses, Edenbridge, Kent, July 7

MR. J. H. A. JENNER says (NATURE, vol. xx. p. 220) that "last season (1878) he saw no specimens of *Vanessa cardui*, nor did he hear of any about Lewes." I would remark that *Vanessa cardui* was exceedingly abundant in the Isle of Wight; I could have caught scores in a few minutes. I would further remark that towards the close of the season I saw beds of nettles, many yards square, literally black with larvæ of *V. cardui*.[1] I anticipated then that they would be abundant this year, and so they are. W. REES SWAIN

Patent Museum, South Kensington, July 4

Intellect in Brutes

As an instance of intelligence in a cat, the following story is, I think, worthy of being recorded in your pages :—

My father, when a boy, kept a tame starling, which, having had its wings clipped, was allowed to hop about the house at random. It had been brought up, so to speak, with a little kitten, and a great friendship had been established between the two, they playing together, drinking out of the same saucer, &c., &c.

One day while the family were at dinner, with open doors, the cat suddenly pounced upon the starling, and every one thought that at last the cat's nature had got the better of its affection; but no. The cat carefully took up the starling, jumped with it on to a table, and leaving it there, rushed out of the room.

A moment after, the sound of a furious fight going on in the hall reached the ears of the astonished family, and it was then found that a strange cat had stolen into the house, with which the starling's friend was fighting. Evidently the house cat heard the approach of the enemy, and having first placed its playfellow in a comparatively safe place, rushed out to expel the intruder. A. DUPRÉ

Kensington, W., July 5

[1] [The larvæ referred to were probably those of *V. atalanta*. *V. cardui* ordinarily feeds on *thistles*.—ED.]

THE letters of X. and of Mr. Henry Clark in NATURE, vol. xx. p. 220, referring to the recognition of portraits by dogs, are, I think, very interesting, as my observations lead me to suppose that it is very rarely that a dog takes any notice of a painting or any representation on the flat. I only know of one instance. A bull terrier of mine was lying asleep upon a chair in the house of a friend, and was suddenly aroused by some noise. On opening his eyes, the dog caught sight of a portrait of a gentleman on the wall not far from him, upon which the light was shining strongly. He growled, and for some little time kept his eyes fixed upon the portrait, but shortly satisfying himself that there was no danger to be apprehended, he resumed his nap. I have often since endeavoured to induce him to pay some attention to portraits and pictures, but without success; but sometimes he will bark at his own reflection in a looking-glass. He knows it to be his own image that he sees, for he very soon tires both of barking and looking. Other authentic instances of this kind would be valuable. J. B. R.

July 4

I SEND the inclosed extract from the *Bedworth Guardian*. I can vouch for the fact, as Hawkesbury Station is near to me, and my son has witnessed the feats of poor Pincher. I trust that it will not be an unwelcome contribution to the interesting series of facts in evidence of animal sagacity recorded in NATURE.

Moat House, Walsgrave, Coventry, July 3

J. S. WHITTEM

"The picturesque little station at Hawkesbury Lane, between Nuneaton and Coventry, has, for some time past, been the home of a fox terrier, known as Pincher, an animal possessing almost human intelligence. Pincher—trained by its owner, Mr. Instone, to do so—would listen with marvellous patience and acuteness for the signal intimating that a train was approaching the station, and then, almost with the speed of lightning, rush to the signal-box, and, seizing the bell between its teeth, shake it heartily, and thus apprise the waiting passengers of the train's approach. This task accomplished, he would descend the steps leading from the box, proudly wagging his tail, and ready and willing, apparently, for any duty he might be called upon to perform. Often, as a train was leaving the station, Pincher would run beside it for about a hundred yards, as though acting under the impression that the engine-driver would be unable to obtain the necessary impetus without his assistance. On Sunday evening last Pincher's career was brought to an untimely end, but he died as became a dog of his attainments and renown, "in harness." Soon after seven o'clock on the evening named, two trains entered the station at one and the same time (Pincher having previously rung the bell), one going towards Nuneaton, the other in the contrary direction. Actuated by some motive or other—probably to see what was going on at the other side of the line—the dog darted under the carriages of the latter train, and one of the wheels passed over his neck, death being instantaneous."

Snails *v.* Glow-worms

WHEN writing on this subject I thought my facts might be questioned, but I did not expect they would be so distorted as they have been by Mr. McLachlan at p. 219.

I simply recorded what I had seen, and in accordance with the request at the head of your column for letters to the Editor, I made my letter "as short as possible."

The heading of my letter was correct, and I described what I certainly saw—a glow-worm in *the inside* of a snail, for when the snail moved its semi-transparent skin was between me and the light. There was no phosphorescent matter on the snail.

If the glow-worm was eating the snail, as both Mr. McLachlan and Mr. Greenwood Penny suggest, then, I conclude, he attacked *the liver*, and not the *lights*, as Mr. Henslow's cat did! At all events my opponents will agree with me in thinking that the snail had a *light* supper! The fact is evidently new to these gentlemen.

I shall feel obliged by any or all of them sending me some glow-worms, and I will try the experiment again, as well as some others. R. S. NEWALL

Gateshead-on-Tyne, July 8

Occurrence of Boar Fish

I RECEIVED several notices of the capture of boar-fish (*Capros aper*), on the south and south-east coasts of England during June

last. First from Bournemouth and Weymouth, where they were found not unfrequently dead on the shore. Again, one of the Leigh "shrimpers" took about a dozen specimens in his trawl net near Sheerness, at the mouth of the Thames. Another two specimens were taken likewise in a shrimp trawl off Harwich. None of these survived, no doubt having been too long in the trawl net, which is frequently three or more hours in the water. Dead specimens of these were sent for my observation, by Mr. Andrew, the aquarium fish collector of Southend-on-Sea. He says the Essex fishermen call them red dorees, but none remember having seen them on that coast before this year.

JOHN T. CARRINGTON

Royal Aquarium, Westminster, July 6

Habits of Ants

MY attention was lately called by a friend to the operations of a party of ants. The theatre of their work was a cherry-tree partly decayed in the centre. From this portion of the tree the busy creatures were bringing forth small grains of sawdust-like *débris*. These particles were conveyed to the prominence left by an amputated branch, and thrown over to the ground, a distance of about five feet. The particles were passed on from one ant to another—as water-buckets were at old-time fires. Nor was this all, for on the ground below, another party removed the accumulated material. In this connection the reader should consult a remarkable note on page 21 of Kerner's "Flowers and their Unbidden Guests" to further illustrate the intelligence of ants and their recognition of the principle of division of labour. I am unable to state the species of ant I observed, as I am not an entomologist. It was a rather large red ant.

WILLIAM FOTHERGILL COOKE

THERE has slipped away noiselessly and quietly one of England's scientific pioneers and one of the world's benefactors. Sir William Fothergill Cooke was the father of electric telegraphy. Born in 1806, educated in Durham, where his father was a professor, he joined the East India Company's military service in 1826, from which he retired in 1835 to study anatomy and physiology in Paris and Heidelberg. He was very clever at wax modelling. In 1836 a lecture on Schilling's telegraph directed his attention to the electric telegraph. His was the active sanguine mind that saw the great future of telegraphy before him, and that, in spite of supineness and unbelief, forced the new agent on an unwilling world. He was not an inventor nor a discoverer, but he was a far-seeing, practical man, with a determined will, indomitable energy, and of great resources. Associated with Wheatstone, he established telegraphy as a commercial undertaking. The first experimental line in England was put up in 1837. The first Electric Telegraph Company was incorporated in 1844. The first cable was laid in 1851. Now the world is one network of wires, and while the pioneer of this great system is carried to his grave, representatives from every civilised nation of the earth meet in telegraphic parliament in London without heaving one sigh or casting one thought

"O'er the grave where our hero we buried."

THE COMPARATIVE ANATOMY OF MAN[1]

II.

The Andaman Islanders (continued)

HITHERTO the osteological characters of these people have only been known from one skeleton, briefly described by Prof. Owen, two crania by Mr. Busk, and two by Prof. Quatrefages. During the last half year, the College museum has received a valuable series of skeletons, collected, at the request of Sir Joseph Fayrer, by the late Dr. J. Dougall, senior medical officer at Port Blair; others have been lent for the purpose of illustrating this course by Professors Rolleston and Allen Thomson, amounting altogether to nineteen skeletons, and about thirty crania.

The common estimate among Europeans, which is fairly correct for averages, is that the length of the femur is to the height of the living person as 275 is to 1,000. Only one of the above-mentioned Andamanese skeletons has been articulated, but this shows exactly the same proportion. Calculated on this basis, the average height of the skeletons of males would be 4 feet 9 inches, the tallest being 5 feet 3 inches, and the shortest 4 feet 6 inches. The average height of the ten skeletons of females would be 4 feet 6 inches, the tallest being 4 feet 10 inches, the shortest 4 feet 3 inches.

Attention was first drawn to the fact that the proportions of the different segments of the limbs might differ in various races by the announcement in 1799, by White, of Manchester, since amply confirmed, that the forearm of the Negro is proportionally longer than that of the European. Unfortunately, skeletons of most races are so rare in collections, that we have at present but few reliable data on this subject, and it is only when a sufficient number can be obtained, on which to found a fair average, that any satisfactory law can be established.

The first ratio, or index, is that obtained by the comparison of the entire upper and lower limbs with each other, the *intermembral index*, or the length of the humerus and radius added together, as compared with that of the femur and tibia, the latter being taken as 100. This ratio, in the nineteen Andaman skeletons, is 68·3; in fourteen Europeans, measured in the same manner, 69·2, showing a slight diminution in the length of the arm of the former, as compared with the latter. This has been also found by Broca, to be the case with African Negroes. The *femoro-humeral index* is the ratio of the humerus to the femur, the latter being taken as 100. In Europeans, according to Prof. Flower's and Broca's measurements, this is 72 to 73; in Negroes, according to Broca, 68·9; in the Andamanese, 69·8; showing that in both the latter races the humerus is relatively shorter than the femur. The *femoro-tibial index* is the length of the tibia to the femur, the latter being 100. In Europeans, this is 82; in Negroes, according to Prof. Humphry, 84·7; in the Andamanese, almost exactly the same, 84·5. The *humero-radial index*, or the length of the radius, compared to the humerus is, perhaps, the most important, as being subject to greater variations in different races. In nine Europeans measured by Broca, it is 73·9; in fourteen Europeans in the College Museum, it is exactly the same; in fifteen Negroes measured by Broca, 79·4; in the nineteen Andamanese, 81. Thus the differential characters of the Andamanese, as compared with Europeans, in respect to the proportions of the limb-bones, lie mainly in the greater length of the distal segment of each limb as compared with the proximal segment, a peculiarity most especially manifested in the upper extremity.

In the *Bulletin* of the Paris Anthropological Society of last year, Broca called attention to the form of the scapula as a race-character, and showed that one of the principal modifications of the form of this bone could be expressed by an index formed of a ratio between the two chief diameters of the bone, *i.e.*, the length from the posterior superior angle (C) to the inferior angle (D), and the breadth from the middle of the posterior margin of the glenoid cavity (A) to the point on the posterior or vertebral border from which the spine arises (B). The ratio of the length (C D) to the breadth (A B), the latter being 100, is called the *scapular index*. In the anthropoid apes the index varies between 70 and 100, and in most of the lower forms of monkeys and other mammals, it is considerably higher. A high index is, therefore, a sign of inferiority. Broca found that the average in

[1] Abstract of Prof. Flower's Hunterian Lectures, delivered at the Royal College of Surgeons, commencing on Wednesday, March 5. Continued from p. 225.

twenty-three Europeans was 65·91, and in 200 scapulæ of Europeans, measured by Dr. Garson, the average index was 65·2. The twenty-five Negro skeletons in the Paris Museum gave an average scapular index of 68·16, and the six scapulæ of the three Negro skeletons in the College Museum, 71·7. Australians give an average of about 68·9. Of the Andaman skeletons, the twenty-one scapulæ which have the epiphyses united give an average index of 69·8, and thus, in this character also, they stand in close relationship to the Negro and to the Australian. Another sign of inferiority in the scapula of the Andamanese is the almost constant absence of the supra-scapular notch.

The pelvis is also very important for comparison, and the difference that is most obvious and easily estimated lies in the form of the superior aperture or brim, which is always more elongated from before backwards, and narrowed laterally in the apes than it is in man. The relation of the antero-posterior to the transverse diameter of the brim, the latter measurement being taken as 100, gives the *pelvic index*. In the anthropoid apes the antero-posterior diameter is always the larger, and in infancy and childhood in our own race the pelvic index is also as high as, or above, 100. In adult man, except in rare cases, the transverse diameter is the greater, and the index consequently below 100, in the female being lower than in the male. In Europeans the average pelvic index is about 81 for the male and 78 for the female sex. The average of 17 male Negroes, according to Verneau, is 89; of ten Australians, according to Prof. Flower, 98; but the Andamanese give the highest figure of all, the average index of 8 males being 101, the maximum being 116 (the highest index of a human pelvis recorded), the minimum 92·6. Of the 9 females the average index is 95·2, the maximum 107·8, the minimum 86·4. No race, of which a sufficient number of pelves to give fair averages have been measured, has shown a form of the pelvis departing so widely from the European type. It should be noted, however, that the difference between the sexes is as fully, or even more fully, pronounced than it is in the higher races, contrary to an idea which has been sometimes held, based, however, upon an insufficient number of observations.

Cranial Characters.—The following observations are founded upon twenty-four specimens, all adults, of which twelve belong to the male and twelve to the female sex. They all present a very considerable general resemblance. They present a peculiar combination of characters, which distinguish them from the crania of all other races, unless it may be some of the closely allied Negrito population of the Indian Archipelago. Among these twenty-four skulls none present any artificial or pathological deformation.

In general size the skulls may be considered as belonging to the smallest, or nearly the smallest, of any race. The cranial capacity of the males ranges between 1,150 and 1,360 cubic centimetres, the average being 1,244 c.c. (76 c. ins); that of the females between 1,025 and 1,250 c.c., the average being 1,128 c.c. (69 c. ins.), the proportion between the two sexes being, therefore, as 1,000 to 906, almost exactly the same as that between English men and women. The average circumference in the male is 480 millimetres; in the female, 462 millimetres.

The general form of the cranium is short and round, and the parietal region is greatly developed at the expense of the frontal, and especially of the occipital regions. The relation of the greatest transverse breadth in the parietal region to the length is expressed by the *latitudinal index* (sometimes called "cephalic index"). This in both sexes averages 820, and they are therefore, as a race, truly brachycephalic, all those skulls, the index of which is above 800, coming into this category. The average index of height—*altitudinal index*—in both sexes is 775, being 770 in the males and 779 in the females. In only one out of the twenty-four skulls is the breadth less than the height; they thus differ greatly from the Papuans and Melanesians.

The sutures of the cranium are, as in most inferior races, rather simple. *Metopism*, or persistence of the mid-frontal suture throughout life, occurs in four out of thirty-four known cases of skulls of Andamanese, and thus seems rather more frequent than among Europeans; this is rather surprising, as it is a character which generally accompanies superiority of development. More skulls, however, must be examined to establish the actual frequency of its occurrence in the race. The disposition of the sutures in the region called *pterion* by Broca, where the frontal, parietal, squamosal, and alisphenoidal bones meet, is always worthy of note in estimating the differential characters of races. In many inferior races the interval between the frontal and squamosal bones is greatly diminished, and often, especially among the Melanesians, disappears altogether, the squamosal then directly uniting with the frontal. Very frequently small independent ossicles, or *epipteric bones*, are interposed.

In the Andamanese the pterion is usually very narrow, but in six only out of forty-six cases examined (taking both sides) did the squamosal reach the frontal. In eight cases epiteric bones were developed. The general surface of the cranium is smooth, and the muscular ridges little pronounced. The forehead is rounded and even, and the glabella and superorbital eminences are always very little developed. The interspace between the orbits is wide and flat, and the orbits are round, the average index, or the ratio of height to width of margin, the latter taken as 100, being as high as 910. The nasal bones are straight, with nearly parallel sides, and not prominent. The width of the nasal opening brings the Andamanese into the mesorhine category of Broca, though approaching the platyrhine, the average index being 512. Of the twenty-four skulls, five are platyrhine, seventeen mesorhine, and two leptorhine. With regard to the projection forward of the jaws, eleven are decidedly prognathous, eight mesognathous, and five orthognathous.

Comparison with other Races.—With the Australians, the Andamanese have very little affinity; it is to the other wooly-haired races that we must naturally turn in endeavouring to find their nearest relatives. The typical Melanesians and Papuans differ greatly in their principal cranial characters; the Tasmanians, also, differed widely from the Andamanese. Many of the African Negroes, again, although usually dolichocephalic, extremely prognathous and platyrhine, have the smooth brow and round orbit seen in the Andamanese, and not generally met with in the true Oceanic Negroes.

The natives of the Andaman Islands, with whom may probably be associated the less known Aetas of the Philippines, the Semangs of the Malay Peninsula, and some other scattered races of the Indo-Malay Peninsula, thus constitute a race apart, to which the name *Negrito* may properly be applied. At first sight, they appear in their craniological characters to present little affinity to either of the other woolly-haired races, but it is probable that they represent a small or infantile type of the same primary group. It is very possible, but this is purely hypothetical, that the Andamanese may be the unchanged or little modified representatives of a primitive type, from which the African Negroes, on the one hand, and the Oceanic Negroes on the other, have taken their origin, and hence everything connected with their history or structure becomes of the greatest interest to the anthropologist.

The Inhabitants of India

By their physical characters, the various populations which inhabit the great continent of Asia attach themselves more or less to one or other of two very distinct types:—I. The *Mongolian;* and II. That which for want of a better name must still be distinguished by the title applied to it by Blumenbach, the *Caucasian.*

Roughly speaking, a line striking northward from the head of the Bay of Bengal, to the Himalayas, then turning westward and skirting the southern flanks of that great mountain-chain, passing north of Cashmere, and in a westward direction to the Sea of Aral, the Caspian, and the Ural Mountains, divides the area occupied by people of each type, those to the east and north of this line being mainly Mongolians, and those to the south and west mainly Caucasians.

The people of India proper, except in the extreme north and north-east, belong mainly to the Caucasian division. It has been thought that other races have contributed a share to the composition of the present population of the Peninsula, having been the earliest inhabitants of the land, and forming, as it were, a substratum of the existing population; these are :—I. Negritos, allied to the Andaman Islanders: II. Australoids, allied to the modern Australians. The search for evidence for or against the existence of these elements in the population of India must naturally be sought for among the tribes which retain more or less of their barbarous condition.

With these must be classed the Veddahs of Ceylon. Many of these people have become civilised, but the wild or "Rock Veddahs" live in a most primitive state of social culture, without clothing, agriculture, or fixed dwellings. They are a dwarfish, stunted race, of blackish complexion. and with straight, though generally unkempt and shaggy hair. The condition of their bones and other physical characters give the impression of their being a race degenerated and enfeebled by generations of privation and other circumstances adverse to full development. There are no Veddah skeletons in the College Museum, but as many as seven crania; one of them, that of a woman, is the smallest adult skull in the whole collection, its cerebral capacity measuring only 960 c.c. (58·6 c. ins.). They are all dolichocephalic, the average latitudinal index being 71·1, and the average altidudinal index 86·1. Their prognathism is not very marked, and the nasal index is medium, averaging 50·3. They enter rather into the type of the lower grades of the inhabitants of Bengal.

The present population of India, excluding the Mongoloid people of the north and east, is separated by language into two great divisions—(1) The Aryans, and (2) The Non-Aryans, the majority of whom speak one of the agglutinative tongues collectively called *Dravidian*. The Aryans came into India by the north-west by way of the Punjaub, about 1,500 years before our era, as is supposed. They now occupy the great alluvial plains of the Indus and Ganges between the Himalayas and the elevated plateau of Central India, and have spread southwards along both coasts as far as Ceylon.

The Dravidians, who occupy the greater part of the country southwards from the Nerbudda River, are supposed to be descended mainly from the people who inhabited the country before the Aryan immigration. They are again divided into two groups—(*a*) The civilised Dravidians, speaking Tamul, Telugu, Canarese, &c., and (*b*) The wild tribes of the mountainous districts of the interior. These "Hill Tribes," as they are often called, are of great interest to the ethnologist, as they represent the oldest stratum of the population. By their languages they are divided into two groups—(1) Those that speak Dravidian, the Gonds, the Khonds, the Oraons, &c.; (2) The Munda or Kolarian family, composed of numerous tribes called Coles, Hos, Moondahs, Santals, Billahs, &c. Very little is known of the physical characters of these people.

Dr. John Shortt has lately sent to the Museum a series of twenty skulls belonging to the tribes of Maravars, who inhabit the Madura district in the south of the peninsula. He has also sent a series of equal number to the Museum of the Paris Anthropological Society, which has been described by M. Callamand in a recent number of the *Revue d'Anthropologie*. As regards the capacity, the average in the Paris skulls is 1,281 c.c., in those sent to the Museum, 1,268 c.c. The average lengths are respectively 174·5 and 175·6, but in the former the projection of glabella is included. The average breadth is 131 in both; the latitudinal index is 746 in the one and 751 in the other series; the altitudinal, the nasal, and the orbital indices are respectively 752 and 758, 521 and 510, 839, and 854. These skulls, on the whole, differ totally from those of the Andamanese, especially in the great development of the occipital region. Nor do they present any striking resemblances either to those of the Australians, or to any of the Mongoloid races. Their characters do not differ much from those of the mixed population of Bengal generally. These Maravars may not belong to the races among which the characters of the original hill-tribes should be looked for, and no evidence has yet been found of cranial conformation bearing out the view of the Australian affinities of these people, derived from external appearance. The presence of a Negrito, *i.e.*, woolly-haired and brachycephalic, element in the population of India, is also based at present on very slender evidence.

(*To be continued*)

ON THE SECULAR EFFECTS OF TIDAL FRICTION[1]

IN three papers, read at different times before the Royal Society, the author has considered the theory of the tides of a viscous spheroid, and the perturbations of the rotation of the spheroid caused by the attraction of the tide-raising satellite; the direction of that investigation was governed by considerations of applicability to the case of the earth, moon, and sun.

In the paper, of which we are here giving an account, the question is considered both from a more general and from a more special point of view than in the previous papers. For it is here supposed that there is only a single tide-raising body or satellite which moves in a circular orbit in the equator of the planet, but the orbital motion may be either consentaneous with or adverse to the planet's rotation. The tides supposed to be raised in the planet by the attraction of the satellite are of any kind whatever, provided that there is a frictional resistance in the planet to the tidal motion. The results are therefore applicable alike to the hypothesis of bodily tides, or to that of oceanic tides.

It results from a general mechanical principle that in whatever way the satellite and planet interact, the whole moment of momentum of the rotation of the system must remain constant; whilst, as there is a frictional resistance in the planet to the tidal motion, the whole energy of the system, viz., the sum of the potential and kinetic energies, must diminish. The method employed to trace the effects of tidal friction consists in drawing two curves, one of which represents the constancy of the moment of momentum, and the other of which gives the energy of the system for each configuration.

Then if we conceive a system of a planet and satellite started in such a way as to be represented by a given point on the curve of conservation of moment of momentum; and if we imagine this point linked to its corresponding point on the curve of energy, since the energy must degrade, the point on the curve of energy must always slide down a slope and carry with it the point on the curve of momentum.

It is thus possible to track the nature of the changes in the configuration of the system, but the method gives no clue to the time occupied by those changes. This comparison of the energy with the moment of momentum of the system by a graphical method was suggested to the author by Sir William Thomson.

[1] A paper read before the Royal Society on June 19, 1879, by G. H. Darwin.

A third curve is also introduced which represents such a rotation of the system that the planet always shows the same face to the satellite, just as we always see the same face of the moon; this curve is called the curve of rigidity, because when the motion is of this kind, the system moves as though the planet and satellite were parts of one rigid body.

It appears from a consideration of these three curves that if the whole momentum of the system be less than a certain amount, then it is not possible to set a given planet and satellite in rotation, so that the planet shall always show the same face to the satellite; but if this can be done at all, it can be done in two ways, and one of those ways corresponds to a maximum amount of energy of the system, and the other to a minimum. Moreover the configuration of maximum energy is one of dynamical instability and the system may degrade in either of two ways from that state. In one of these modes of degradation the satellite approaches and falls into the planet, and in the other it recedes from the planet.

Part of the author's previous papers consists in tracing backwards the moon's motion from its present condition to that configuration of maximum energy; and it was found that that state corresponded with a rotation of the earth and moon, like the parts of one rigid body, in about five hours. This rapid periodic time of the moon corresponds with only a few thousands of miles intervening between the earth's surface and that body. Since the tides on the earth must be subject to friction, it follows inevitably that, if time enough has elapsed since the origin of the moon and earth, the present state must be a degradation of the configuration of maximum energy, which cannot itself be a degradation of a previous state. And therefore it was maintained that this closeness of the two bodies points to the community of their origin.

In this mode of evolution we see that the rotation and revolution of the two bodies was primitively such that the month and day were of equal length (about five hours), and that in the future they will again come to equality, each being then about fifty of our days long. From this it follows that the system must pass through some phase in which there is a maximum number of planetary rotations during one revolution of the satellite, or shortly there must, at some time, be a maximum number of days in the month. Numerical calculation shows that for the earth and moon that maximum number is about 29, and that at present, when we have $27\frac{1}{3}$ days in the sidereal month, we have slightly passed that maximum.

From a further consideration of the figures it appears that if the planet and satellite are set in motion with opposite rotations, the satellite will fall into the planet if the moment of momentum of orbital motion be less than or equal to, or only greater, by a certain critical amount than the moment of momentum of planetary rotation; but if it be greater by more than a certain critical amount the satellite will approach the planet, the rotation of the planet will stop and reverse, and finally the system will come to equilibrium when the two bodies move round as a rigid body, with a long periodic time.

If the rate of the planet's rotation be less than that of the satellite's revolution, so that the sidereal month is shorter than the day (as with the inner satellite of Mars), then the satellite will either approach the planet and ultimately fall into it, or will approach the planet and will finally move round the planet at the same rate as the planet rotates. It depends on the nature of the system, as to which of these two cases will be the result.

The method is then extended to the case where the satellite, instead of being merely an attractive particle, is also a spheroid rotating about an axis perpendicular to the plane of the orbit. In this case the graphical illustration is by means of surfaces, there being one surface representing conservation of moment of momentum, and another representing the energy of the system. Each point on one surface has a corresponding point on the other surface, and the point on the energy surface must always slide down hill. It is not necessarily the case that the descent should be down a line of greatest slope. Illustrations are given to show that a point on an energy surface may sometimes depart from the bottom of a furrow, or may descend a ridge on the surface. The path to be followed by the point on the energy surface depends on the nature of the tides raised in the two bodies. Thus the solution in this case is not determinate, without some further knowledge of the system.

MORE NOTES FROM KILBURN

THE gas and petroleum-engines make a fair show. The Otto silent gas-engine, however, seems still to hold its own, other constructions having, so far as one can judge from a short inspection at Kilburn, some defect or other, such as noisy working, or a dangerous-looking outside flare of the ignited gas. One striking novelty is shown in this section, namely, an invention of Mr. Dugald Clerk, whereby the gaseous mixture is lighted by a cage of platinum wire, which retains heat enough from one ignition to the next to be effective for this purpose. It is stated that 400 ignitions have been made in the cylinder of an engine of this type in one minute. There are other distinctive contrivances in this gas-engine, which, by the by, is the manufacture of Messrs. Thomson, Sterne, and Co., and altogether shows great ingenuity. One of the engines exhibited by this firm is described as a "Domestic Motor," of $\frac{1}{10}$ horse-power, costing but 15*l.*, and deriving its power from steam generated by the ignition of air and gas. Such an engine seems admirably fitted for private use in laboratories and small workshops as well as in houses.

Self-binding harvesters, in which wire is used for the automatic tying-up of the sheaves, are attracting much attention, now that millers have adopted the use of magnets, preferably electro-magnets, to separate any bits of iron wire that may happen to get mixed with the grain.

The machinery and implements employed in butter-making and cheese-making afford a striking example of the advantages resulting from the application of scientific exactness to a most useful art. The question of temperature in every operation of the dairy is now recognised as of extreme importance. The thermometer reigns supreme in the interesting tent where dairying is shown. The material, the depth, and the diameter of the pans for "setting" milk have been duly studied. Though the processes and instruments exhibited in action are few in comparison with those at the previous shows at Hamburg and other special gatherings, yet the exhibits of Mr. E. Ahlborn and of the Aylesbury Dairy Company are worth attentive study. We noted especially an ingenious butter-squeezer or presser, which removes in the most effectual way that very variable and often excessive quantity of butter-milk and water and of interstitial air which occur in ordinary butter, even when quite genuine. Not only is liability to change and decomposition much lessened by this operation, but constancy of composition is secured, and we no longer find the proportion of water in fresh butter ranging between 6 and 20 per cent.

Messrs. F. H. Atkins and Co. show some good models and examples of their water-filters and other sanitary appliances in connection with water supply. One of their contrivances is specially clever. The surfaces of filtering media of course become rapidly clogged and useless when the water supply is particularly turbid. The vertical surfaces of Atkins's cloth filters are so arranged as to be capable of rotation against a rotating cylindrical brush, set vertically, and accommodating itself perfectly to the surface to be cleansed.

An instructive section of the Kilburn Show is that devoted to hops. From a paper issued by Messrs. John

Barth and Sons, of Nuremberg, we glean some interesting data as to the hop production of the world; this firm also exhibits a diagram of hop-prices from 1798 to 1878. Some samples of hops preserved for two years or more by a process, of which the nature is kept secret, are perfect in aroma and colour. Compression, cold, and exclusion of air are elements of the process but do not suffice to account for its success. The total amount of hops grown in the world in 1878 is stated by Messrs. Barth to be—

	cwts.
England	650,000
Continental Europe	619,000
America	220,000
Total	1,489,000

Many most instructive data as well as specimens, models' and instruments, frequently showing novel applications of scientific principles, may be studied at the Kilburn Show. We had noted for remark the malt-cake exhibited on Stand 586, and the splendid collection of seeds, roots, and models shown by Sutton and Sons of Reading, but the limit of the space at our disposal preclude us from further dwelling upon this exhibition, with its perplexing but most interesting collections.

OUR ASTRONOMICAL COLUMN

THE NEW COMET (SWIFT, JUNE 20).—From observations at Strasburg by Prof. Winnecke on June 21, 26, and July 2, Dr. Küstner, one of his pupils, has computed the following elements of this comet, taking account of all the small corrections:—

Perihelion passage, 1879, April 27·3357 M.T. at Berlin.

Longitude of perihelion	42° 28′ 30″·8	Mean equinox 1879·0.
,, ascending node ...	45 33 36·6	
Inclination to ecliptic	72 59 52·5	
Log. perihelion distance	9·948935	

Motion—retrograde.

From this orbit it appears that on Tuesday next, July 15, the comet will make an exceedingly close approach to the pole of the equator; at 10h. G.M.T. its calculated position is in right ascension 15h. 20m., and declination 89° 42′, but earlier in the evening its distance from the pole may be little over 10′.

We extract the following positions from an ephemeris for Berlin midnight, communicated by Prof. Winnecke:—

1879.	Right Ascension. h. m. s.	North Declination. ° ′	Log. distance from Earth.	Log. distance from Sun.
July 11 ...	2 57 59	85 59·2	0·2209	0·1940
12 ..	2 58 6	87 4·8		
13 ...	2 57 40	88 10·3	0·2226	0·2010
14 ...	2 53 50	89 15·6		
15 ...	15 18 0	89 39·2	0·2247	0·2080
16 ...	15 6 32	88 34·3		
17 ..	15 5 33	87 29·6	0·2271	0·2148
18 ...	15 5 36	86 25·0		
19 ...	15 5 56	85 20·7	0·2300	0·2216
20 ...	15 6 25	84 17·0		

TEMPEL'S COMET, 1867 II.—In a letter addressed to *The Observatory*, communicating his observations of this comet made during the present reappearance, at Florence, Dr. Tempel remarks: "Since it will approach Jupiter nearer in the year 1882 than in the year 1870, we shall probably have difficulty in seeing it again, if we ever do so." This statement must rest upon some misconception or error of calculation. The mean daily motion at the perihelion passage in the present year would not differ materially from 593″·18 as fixed by M. Raoul Gautier, and the perihelion passage having taken place about May 6·98 G.M.T., it will appear that when the comet is next in aphelion (which is about the nearest point of approach to the orbit of Jupiter) early in May, 1882, the actual distance between the two bodies is rather more than 0·75 of the earth's mean distance from the sun, though in the actual orbit it might happen that at this point the comet and planet approach within 0·3. Neglecting the effect of perturbation in the interim, it will be found from M. Gautier's elements that the nearest approach of the comet to Jupiter during the next revolution will occur in October 1881, when their mutual distance will be rather less than 0·58. In January 1870, according to Dr. Seeliger's computation this distance was only 0·32. Although, therefore, the perturbations during the ensuing revolution may be very sensible, they will not produce so great an effect upon the elements of 1879 as to bear out Dr. Tempel's statement.

Observations of this comet have been made at the Observatory of Rio de Janeiro, where the comet was found independently by M. Cruls. The Emperor of Brazil, who appears to take a personal interest in the proceedings of his astronomical establishment, has communicated these observations to the Paris Academy of Sciences, of which his Majesty is a Corresponding Member.

THE VARIABLE-STAR PIAZZI XIII. 126.—Mr. Burnham draws attention to an interesting discovery he has made respecting this object, viz., that it is really a close double star, the components of nearly equal magnitude 6·2 and 6·5, at a central distance of 0″·48 on an angle of 80°·4 for 1879·4. Attention was first directed to its variability by Dr. Julius Schmidt, of Athens, in June, 1866. On the 6th of that month he found it 5·4m. more conspicuous than *i* Virginis, with a yellowish white light contrasting with the orange tinge of the latter star. Piazzi estimated it 6·7m. and 7m., not 8m., as given in his Catalogue; Lalande called it 6·7, Brisbane 6, Heis 6·7, and it is 7m. on Bremicker's chart; it is No. 1,342 of Lamont, who estimated it only 8m. It is worthy of note that the star occurs in the Uranometry of Al Sufi, translated by Prof. Schjellerup in 1874; it is No. 19 of the constellation Virgo in the catalogue of the Persian astronomer, and rated 5·6m. As Mr. Burnham remarks, it will be easy to determine which, if only one, of the stars is variable. The star is B.A.C. 4,531 and No. 1,244 of the new Greenwich Nine-Year Catalogue. Its position for 1880·0 is in R.A. 13h. 28m. 18s., N.P.D. 102° 35′·9.

GEOGRAPHICAL NOTES

A PRIVATE letter received at Carlscrona from the commander of the steamer *Vega* reports all on board in good health. The *Vega* left the mouth of the Lena on August 27. At first she made tolerably good progress, although she had to contend with ice and shoals. The voyage was continued to Cape Yakow, but there she was stopped for three days. The steamer got away from there on September 11, and after a difficult passage reached Cape North on the 13th, where she remained beset until the 18th. After that date the steamer could only now and then make progress on account of the ice. On September 28 the expedition attained this present position, which is situated in lat. 67° 6′, long. 173° 30′. If the *Vega* had got there two days earlier she would have reached Behring Straits. The ship is not lying in a harbour, but alongside a very low sandy shore, made fast to the ground ice. Every one was well, and there was a good supply of provisions and enough coal on board to steam 2,000 miles. One or two villages had been passed, the inhabitants of which are Tschutsches. Their complexion is tawny and their hair and eyes are black. They dress in clothes made of reindeer skin, reside in skin tents, and live on seal blubber. They are singularly amiable and obliging; the women have their faces tattooed, but the men have not. Their language is very hard to understand, but

the explorers have learnt it, and have compiled a Swedish Tschutschisk lexicon of over 300 words. There are three Tschutschisk villages in the neighbourhood of the *Vega*. The temperature in September seldom went down below 3 deg., and the lowest was 5 deg. (Centigrade). On the darkest day of the year, December 21, the sun was above the horizon. The letter was sent off from the *Vega* by a chief who was on a visit, and who lives near Anadyrsk. The explorers expected to get free about July 1, and to reach Japan about August 15.

MAJOR SERPA PINTO, the Portuguese African explorer, of whose journey we gave some account last week, arrived in London on Monday last. We understand that the Royal Geographical Society do not contemplate holding a special meeting in Major Pinto's honour, but that he will be entertained by the Earl of Northbrook, President of the Society, at a private reception on July 16, to which the leading geographers have been invited.

NEWS has arrived at Lisbon that the Portuguese explorers Capello and Ivens, who started with Major Pinto, were on the margin of the river Lucala on April 5, studying the regions crossed by the river Cubango. They had explored the Cubango from its source to the eighth parallel.

THE steamer *Jeannette*, with the Arctic Exploring expedition of the *New York Herald*, sailed on Tuesday from San Francisco for the Arctic seas, *viâ* Behring Straits. The commander is Lieut. De Long, and among the scientific staff is Mr. J. J. Collins, who expects to obtain important data in meteorology to the north of Behring Straits. The detailed plans of the expedition are purposely kept secret.

IN the current number of the *Church Missionary Intelligencer* we find an interesting account, by the Rev. C. T. Wilson, of his voyage across the Victoria Nyanza, from Uganda to Kagei, in the course of which he was able to make some important additions to our knowledge of the geography of the large group of islands at the north-western corner of the lake. He proved conclusively that Mr. Stanley is in error in placing one large island there, to which he gives the name of Sesse, as in reality there are about 150 islands. Passing down the western coast, Mr. Wilson came to the Kagera, or Kitangule River, the Alexandra Nile of Stanley. South of this, he says, the scenery underwent a great change. Previously the shore had been low, clothed with dense forest, and often fringed with beds of papyrus, while to the south the country consisted of high downs, ending in abrupt precipices, 300 or 400 feet high, which sometimes descended sheer down into the lake, and at others had a low strip of alluvial land at their base, dotted with villages. The geological formation also changed. North of the Kagera the rocks were mostly a hard conglomerate, the matrix being clay iron ore, in which quartzose pebbles were imbedded, but on the south they were clay slate, with red sandstone, the strata being inclined in a westerly direction at an angle of about 15°. Besides occasional descriptions of the country and scenery, Mr. Wilson's journal contains some interesting notes on natural history and on the customs of the people.

MR. SANFORD FLEMING, C.M.G., the engineer-in-chief, has just issued his annual report in reference to the Canadian Pacific Railway, illustrated by an interesting map of the prairie region. Mr. Fleming has endeavoured to collect all known information respecting the country within the limits of the prairie region, and, to make it easy of reference, the whole region has been subdivided into blocks, bounded by each separate parallel of latitude and longitude; the descriptions of scientific travellers and all available statements made on reliable authority are placed side by side. Much still remains to be discovered respecting large tracts of country, and Mr. Fleming suggests that the information should be obtained during the present season by careful explorations of the sections where our knowledge is deficient. On the map an attempt has been made to indicate generally the character of the soil, separating that of more or less value from tracts which are comparatively worthless.

IN the fifteenth part of the great map of Switzerland recently published at Berne, the following sheets will be found useful by English tourists in the coming season:—No. 263, Glarus; 367, Wimmis; 429, St. Maria, and 429 *bis*, Stilfser Joch (giving the Swiss portion of the Stelvio); and 526, Martigny, 529, Orsières, and 532, Grand St. Bernard (giving the whole of the Swiss side of the St. Bernard Pass). The present issue is in no respect inferior to the earlier ones, which, we have frequently pointed out, have been remarkable for their uniform excellence. When all the sheets are published, and this will occur in about twelve years' time if the present rate of issue is maintained, Switzerland will be able to boast of a map of a far higher and more useful order than is possessed by any other country in the world.

M. DE LESSEPS gave a long address at the last sitting of the Paris Geographical Society on the Panama Canal. He announced that he had entered into a contract with the Société d'Études for purchasing their rights so as to have the whole of the affair in his own hands. He stated that he had paid a deposit of 80,000*l*. to the Venezuelan Government, and his intention was to establish a public subscription of 16,000,000*l*. He thought that sum should be sufficient with the sale of land conceded by the local government, and that the canal should be finished in less than eight years. In his speech M. de Lesseps narrated a circumstance quite unknown of the career of Napoleon III. When he was a prisoner in Ham he sent one of his friends to survey the canal by Nicaragua. He was so well satisfied with the results of the inspection that he wrote a petition to the Government asking to be liberated from his life confinement, in order to devote his activity to the establishment of this great work, pledging his word of honour that he should no more meddle with politics. The petition was left unanswered. He was ready to go to Nicaragua in order to execute his long-cherished scheme, when the Revolution of 1848 broke out and changed his plans.

THE New York *Nation* records with great satisfaction the formal presentation to the U.S. Government of the invaluable collection of Indian portraits and curiosities made by the late George Catlin. This collection was, a generation ago, one of the standing attractions of London, was afterwards exhibited in Belgium, and there fell into the hands of the late Joseph Harrison, Jun., of Philadelphia, who not only helped Mr. Catlin out of his financial straits by the purchase, but intentionally preserved for his country this most remarkable record of the American aborigines. His widow has now offered it to the National Museum, where it will be duly displayed.

M. DE BRAZZA, the explorer of the Ogowé, and gold medallist of the French Geographical Society, has been summoned to Rome, where he received from the Italian Geographical Society another gold medal for his exploring work. M. de Brazza is an Italian by birth, having become French by naturalisation.

THE new *Bulletin* of the Antwerp Geographical Society contains a geographical sketch of Afghanistan, accompanied by a map, by Lieut.-Col. Adan, who appears to be the mainstay of both the Belgian societies.

THE telegraph line between Tientsin and Taku, in Northern China, was completed on May 8.

THE Japanese Government intend to connect the Loo-choo Islands with Japan by a submarine telegraph cable to Kagoshima.

MOLECULAR PHYSICS IN HIGH VACUA [1]

II.

I HAVE hitherto spoken of and illustrated these phenomena in connection with *green* phosphorescence. It does not follow, however, that the phosphorescence is always of that colour. This coloration is a property of the particular kind of glass in use in my laboratory. I have here (Fig. 7) three bulbs composed of different glass: one is uranium glass (*a*), which phosphoresces of a dark green colour; another is English glass (*b*), which phosphoresces of a blue colour; and the third (*c*) is soft German glass—of which most of the apparatus before you is made—which phosphoresces of a bright apple-green colour. It is therefore plain that this particular green phosphorescence is solely due to the glass which I am using. Were I to use English glass I should have to speak of blue phosphorescence, but I know of no glass which is equal to the German in brilliancy.

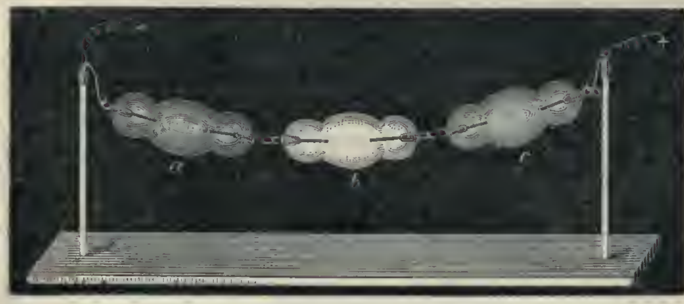

FIG. 7.

My earlier experiments were almost entirely carried on by the aid of the phosphorescence which glass takes up when it is under the influence of the electric discharge *in vacuo*; but many other substances possess this phosphorescent power, and some have it in a much higher degree than glass. For instance, here is some of the luminous sulphide of calcium prepared according to M. Ed. Becquerel's description. When it is exposed to light—even candlelight—it phosphoresces for hours with a rich blue colour. I have prepared a diagram with large letters written in this luminous sulphide; before it is exposed to the light the letters are invisible, but Mr. Gimingham has just exposed it in another room to burning magnesium, and now it is brought into the darkened theatre you will see the word "φῶς,"—*light*, a very suitable word for so beautiful a phosphorescence—shining brightly in luminous characters. The first letter, φ, shines with an orange light; it is a sulphide of calcium prepared from oyster-shells. The other letters, shining with a blue light, are sulphide of calcium prepared from precipitated carbonate of lime. Once the phosphorescence is excited the letters shine for several hours. I will put the diagram at the back, and we shall see how it lasts during the remainder of the lecture. This substance, then, is phosphorescent to light, but it is also much more strongly phosphorescent to the molecular discharge in a good vacuum, as you will see when I pass the discharge through this tube (Fig. 8). The white plate (*a*, *b*) in the centre of the tube is a sheet of mica painted over with the luminous sulphide of which the letter φ was composed in the diagram you have just seen. On connecting the poles with the coil, the mica screen glows with a strong yellowish green light, bright enough to illuminate all the apparatus near it. But there is another phenomenon to which I now desire to draw attention: on the luminous screen is a kind of distorted star-shaped figure. A little in front of the negative pole I have fixed a star (*c*) cut out in aluminium, and it is the image of this star which you see on the screen. It is evident that the rays coming from the negative pole project an image of anything that happens to be in front of it. The discharge, therefore, must come from the pole in straight lines, and does not merely permeate all parts of the tube and fill it with light as it would were the exhaustion less good. Where there is nothing in the way the rays strike the screen and produce phosphorescence, and where there is an obstacle they are obstructed by it, and a shadow is thrown on the screen. I shall have more to say about this shadow presently; I merely now wish to establish the fact that these rays driven from the negative pole produce a shadow.

FIG. 8.

I must draw your attention to an important experiment connected with these molecular rays, but unfortunately it is a very delicate one, and very difficult to show to many at once; but I hope, if you know beforehand what to look for, you will all be able to see what I wish to show. In this pear-shaped bulb (Fig. 9A) the negative pole (*a*) is at the pointed end. In the middle is a cross (*b*) cut out of sheet aluminium, so that the rays from the negative pole projected along the tube will be partly intercepted by the aluminium cross, and will project an image of it on the hemispherical end of the tube which is phosphorescent. I think you will all now see the shadow of the cross on the end of the bulb (*c*, *d*), and notice that the cross is black on a luminous ground. Now, the rays from the negative pole have been passing by the side of the aluminium cross to produce the shadow; they have been hammering and bombarding the glass till it is appreciably warm, and at the same time they have been producing another effect on that glass—they have deadened its sensibility. The glass has got tired, if I may use the expression, by the enforced phosphorescence. Some change has been produced by this bombardment which will prevent the glass from responding easily to additional excitement; but the part that the shadow has fallen on is not tired—it has not been phosphorescing at all, and is perfectly fresh; therefore if I throw this star down—I can easily do so by giving the apparatus a slight jerk, for it has been most ingeniously constructed with a hinge by Mr. Gimingham—and so allow the rays from the negative pole to fall

FIG. 9 A.

FIG. 9 B.

[1] A short-hand report of a lecture delivered at the Royal Institution on Friday, April 4, 1879. By William Crookes, F.R.S. Contributed by the author. Continued from p. 231.

uninterruptedly on to the end of the bulb, you will suddenly see the black cross (c, d, Fig. 9B) change to a luminous one (e, f), because the background is only faintly phosphorescing, whilst the part which had the black shadow on it retains its full phosphorescent power. The luminous cross is now dying out. This is a most delicate and venturous experiment, and I am fortunate in having succeeded so well, for it is one that cannot be rehearsed. After resting for a time the glass seems to partly recover its power of phosphorescing, but it is never so good as it was at first.

We have, therefore, found an important fact connected with

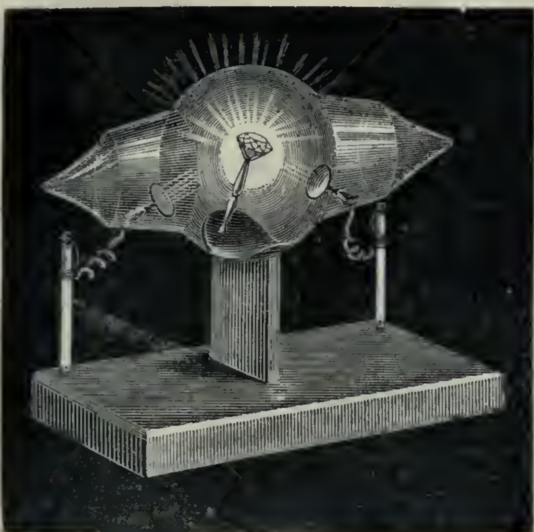

Fig. 10.

this phosphorescence. Something is projected from the negative pole which has the power of hammering away at the glass in front of it, in such a way as to cause it not only to vibrate and become temporarily luminous while the discharge is going on, but to produce an impression upon the glass which is permanent. The explanation which has gradually evolved itself from this series of experiments is this:—The exhaustion in these tubes is so high that the dark space, as I showed you at the commencement of this lecture, that extended round the negative pole, has widened out till it entirely fills the tube. By great rarefaction the mean free path has become so long that the hits in a given

Fig. 11

time may be disregarded in comparison to the misses, and the average molecule is now allowed to obey its own motions or laws without interference. The mean free path is in fact comparable to the dimensions of the vessel, and we have no longer to deal with a *continuous* portion of matter, as we should were the tubes less highly exhausted, but we must here contemplate the molecules *individually*. At first this was only a convenient working hypothesis. Long-continued experiment then raised this provisional hypothesis almost to the dignity of a theory, and now the general opinion is that this theory gives a fairly correct explanation of the facts. In these highly exhausted vessels the mean free path of the residual molecules of gas is so long that they are able to drive across from the pole to the other side of the tube with comparatively few collisions. The negatively electrified molecules of the gaseous residue in the tube therefore dash against anything that is in front, and cast shadows of obstacles just as if they were rays of light. Where they strike the glass they are stopped, and the production of light accompanies this sudden arrest of velocity.

Other substances besides English, German, and uranian glass, and Becquerel's luminous sulphides are also phosphorescent. I think, without exception, the diamond is the most sensitive substance I have yet met for ready and brilliant phosphorescence. I have here a tube, similar to those already exhibited, containing a mica screen painted with powdered diamond, and when I turn on the coil, the brilliant blue phosphorescence of the diamond can be seen, quite overpowering the green phosphorescence of the glass. Here, again, is a very curious diamond, which I was fortunate enough to meet with a short time ago. By daylight it is green, produced, I fancy, by an internal fluorescence. The diamond is mounted in the centre of this exhausted bulb (Fig. 10), and the negative discharge will be directed on it from below upwards. On darkening the theatre you see the diamond shines with as much light as a candle, phosphorescing of a bright green.

In this other bulb is a remarkable collection of crystals of diamonds, which have been lent me by Prof. Maskelyne. When I pass the discharge over them I am afraid you will only be able to see a few points of light, but if you will examine them after the lecture, you will see them phosphoresce with a most brilliant series of colours—blue, apricot, red, yellowish green, orange, and pale green.

Next to the diamond the ruby is one of the most remarkable stones for phosphorescing. In this tube (Fig. 11) is a collection of ruby pebbles, for the loan of which I am indebted to my friend Mr. Blogg, of the firm of Blogg and Martin, who placed a small sackful at my disposal. As soon as I turn on the induction spark you will see these rubies shining with a brilliant rich red colour, as if they were glowing hot. Now the ruby is nothing but crystallised alumina with a little colouring-matter, and it became of great interest to ascertain whether the artificial ruby made by M. Feil, of Paris, would glow in the same manner. I had simply to make my wants known to M. Feil, and he immediately sent me a box containing artificial rubies and crystals of alumina of all sizes, and from those I have selected the mass in this tube which I now place under the discharge: they phosphoresce of the same rich red colour as the natural ruby. It scarcely matters what colour the ruby is, to begin with. In this tube of natural rubies there are stones of all colours—the deep red ruby and the pale pink ruby. There are some so pale as to be almost colourless, and some of the highly-prized tint of pigeon's blood; but in the vacuum under the negative discharge they all phosphoresce with about the same colour.

As I have just mentioned, the ruby is crystallised alumina. In a paper published twenty years ago by Ed. Becquerel,[1] I find that he describes the appearance of alumina as glowing with a rich red colour in the phosphoroscope (an instrument by which the duration of phosphorescence in the sunlight can be examined). Here is some chemically pure precipitated alumina which I have prepared in the most careful manner. It has been heated to whiteness, and you see it glows with the rich red colour which is supposed to be characteristic of alumina. The mineral known as corundum is a colourless variety of crystallised alumina. Under the negative discharge in a vacuum, corundum phosphoresces of a rose-pink colour. There is another curious fact in which I think chemists will feel interested. The sapphire is also crystallised alumina, just the same as the ruby. The ruby has a little colouring-matter in it, giving it a red colour; the sapphire has a colouring-matter which gives it a blue colour, whilst corundum is white. I have here in a tube a very fine crystal of sapphire, and, when I pass the discharge over it, it gives alternate bands of red and green. The red we can easily identify with the glow of alumina; but what is the green? If alumina is precipitated and purified as carefully as in the case I have just mentioned, but in a somewhat different manner, it is found to glow with a rich green colour. Here are the two specimens of alumina in tubes, side by side. Chemists would say that there was no difference between one and the other; but I connect them with the induction-coil, and you see that one glows with a bright green colour, whilst the other glows with a rich red colour. Here is a fine specimen of chemically pure alumina,

[1] *Annales de Chimie et de Physique*, 3rd series, vol. lvii. p. 50, 1859.

sent me by Messrs. Hopkin and Williams; by ordinary light it is a perfectly white powder. It is just possible that the rich fire of the ruby, which has caused it to be so prized, may be due not entirely to the colouring-matter, but to its wonderful power of phosphorescing with a deep red colour, not only under the electric discharge in a vacuum, but whenever exposed to a strong light.

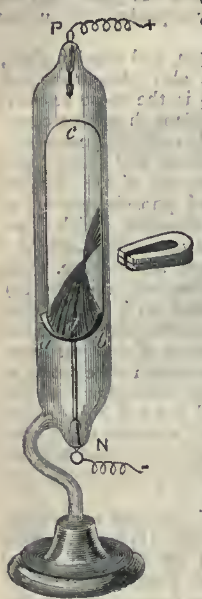

FIG. 12.

The spectrum of the red light emitted by all these varieties of alumina—the ruby, corundum, or artificially precipitated alumina—is the same as described by Becquerel twenty years ago. There is one intense red line, a little below the fixed line B in the spectrum, having a wave-length of about 6895. There is a continuous spectrum beginning at about B, and a few fainter lines beyond it, but they are so faint in comparison with this red line that they may be neglected. This line may be called the characteristic line of alumina.

I now pass on to another fact connected with this negative discharge. Here is a tube (Fig. 12) with a negative pole (a, b) in the form of a hemi-cylinder, similar to the one you have already seen (Fig. 3), but in this case I receive the rays on a phosphorescent screen (c, d). See how brilliantly the lines of discharge shine out, and how intensely the focal point is illuminated; it lights the whole table. Now I bring a small magnet near, and move it to and fro; the rays obey the magnetic force, and the focus bends one way and the other as the magnet passes it. I can show this magnetic action a little more definitely. Here is a long glass tube (Fig. 13), very highly exhausted, with a negative pole at one end (a) and a long phosphorescent screen (b, c) down the centre of the tube. In front of the negative pole is a plate of mica (b, d) with a hole (e) in it,

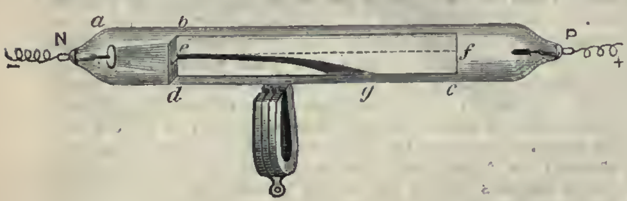

FIG. 13.

and the result is that when I turn on the current, a line of phosphorescent light (e, f) is projected along the whole length of the tube. I now place beneath the tube a powerful horse-shoe magnet: see how the line of light becomes curved under the

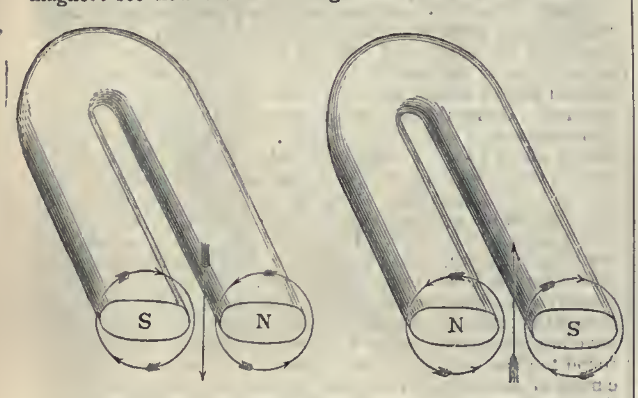

FIG. 14.

magnetic influence (e, g), waving about like a flexible wand as I move the magnet up and down. The action of the magnet can be understood by reference to this diagram (Fig. 14). The north pole gives the ray of molecules a spiral twist one way, and the south pole twists it the other way; the two poles side by side compel the ray to move in a straight line up or down, along a plane at right angles to the plane of the magnet and a line joining its poles.

Now it is of great interest to ascertain whether the law governing the magnetic deflection of the trajectory of the molecules is the same as has been found to hold good at a lower vacuum. The former experiment was with a very high vacuum. This is a tube with a low vacuum (Fig. 15). On passing the induction spark it passes as a narrow line of violet light joining the two poles. Underneath I have a powerful electro-magnet. I make contact with the magnet, and the line of light dips in the centre towards the magnet. I reverse the poles, and the line is driven up to the top of the tube. Notice the difference between the two phenomena. Here the action is temporary. The dip takes place under the magnetic influence; the line of discharge then rises, and pursues its path to the positive pole. In the high exhaustion, however, after the ray of light had dipped to the magnet it did not recover itself, but continued its path in the altered direction.

During these experiments another property of this molecular discharge has made itself very evident, although I have not yet drawn attention to it. The glass gets very warm where the green phosphorescence is strongest. The molecular focus on the tube, which we have just seen (Fig. 12) would be intensely hot, and I have prepared an apparatus by which this heat at the focus can be intensified and rendered visible to all present. This small tube (a) (Fig. 16) is furnished with a negative pole in the form of a cup (b). The rays will therefore be projected to a focus in the middle of the tube (Fig. 17, a). At the side of the tube is a small electro-magnet, which I can set in action by touching a key, and the focus is then drawn to the side of the glass tube (Fig. 17, b). To show the first action of the heat I have coated the tube with wax. I will put the apparatus in front of the electric lantern (d), and throw a magnified image of the tube on the screen. The coil is now at work, and the focus of molecular rays is projected along the tube. I turn the magnetism on, and draw the focus on the side of the glass. The first thing you see

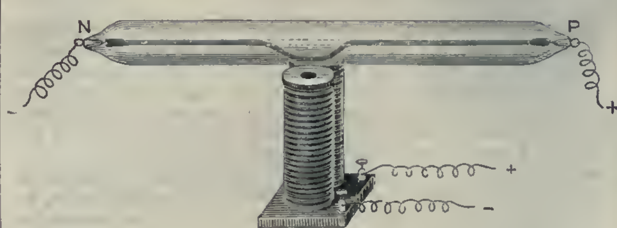

FIG. 15.

is a small circular patch melted in the coating of wax. The glass soon begins to disintegrate, and cracks are shooting star-wise from the centre of heat. The glass is softening. Now the atmospheric pressure forces it in, and now it melts. A hole (c) is perforated in the middle, the air rushes in, and the experiment is at an end.

Instead of drawing the focus to the side of the glass with a magnet, I will take another tube (Fig. 18), and allow the focus from the cup-shaped negative pole (a) to play on a piece of platinum wire (b) which is supported in the centre of the bulb. The platinum wire not only gets white-hot, but you can see sparks coming from it on all sides, showing that it is actually melting.

Here is another tube, but instead of platinum I have put in the focus that beautiful alloy of platinum and iridium which Mr. Matthey has brought to such perfection, and I think that I shall succeed in even melting that. I first turn on the induction-coil slightly, so as not to bring out its full power. The focus is now playing on the iridio-platinum, raising it to a white heat. I bring a small magnet near, and you see I can deflect the focus of heat just as I did the luminous focus in the other tube. By shifting the magnet I can drive the focus up and down, or draw it completely away from the metal, and render it non-luminous. I withdraw the magnet, and let the molecules have full play again; the metal is now white-hot. I increase the intensity of the spark. The metal glows with almost insupportable brilliancy, and at last melts.

There is still another property of this molecular discharge, and it is this:—You have seen that the molecules are driven

violently from the negative pole. If I place something in front of these molecules, they show the force of impact by the heat which is produced. Can I make this mechanical action evident in a more direct way? Nothing is simpler. I have only to put some easily moving object in the line of discharge in order to get a powerful mechanical action. Mr. Gimingham, with great

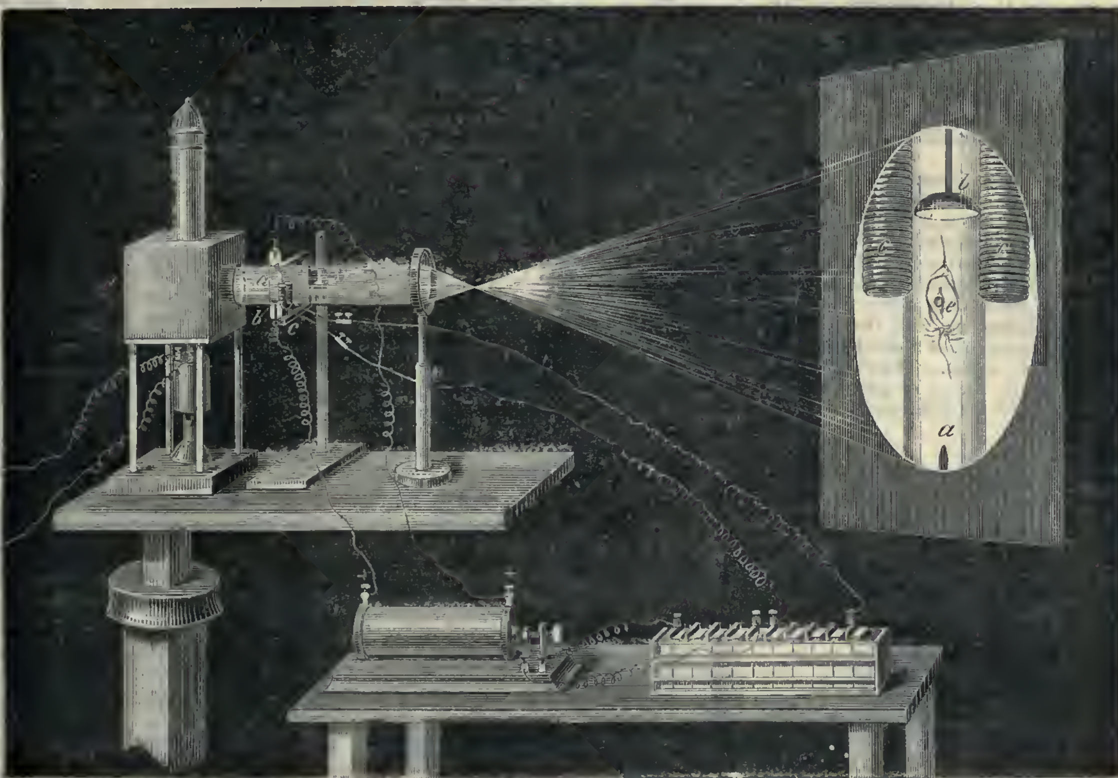

FIG. 16.

skill, has constructed a piece of apparatus which I will presently put in the electric lantern, so that all will be able to see its action. But first I will explain the construction by means of this diagram (Fig. 19). The negative pole (a, b) is in the form of a very shallow cup. In front of the cup is a mica screen

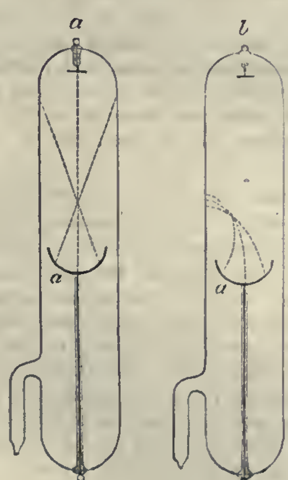

FIG. 17.

(c, a), wide enough to intercept nearly all the molecular rays coming from the negative pole. Behind this screen is a mica wheel (e, f) with a series of vanes, making a sort of paddle-wheel of it. So arranged, the molecular stream from the pole a b will nearly all be cut off from the wheel, and what escapes over and under the screen will hit the vanes equally, and will not produce any movement. I now put a magnet, g, over the tube, so as to

FIG. 18.

deflect the stream over or under the obstacle c d, and the result will be rapid motion in one or the other direction, according to

the way the magnet is turned. I now throw the image of the apparatus on the screen. The spiral lines painted on the wheel show which way it turns. I arrange the magnet to draw the molecular stream so as to beat against the upper vanes, and the wheel revolves rapidly, as if it were an over-shot water-wheel. I now turn the magnet so as to drive the molecular stream underneath; the wheel slackens speed, stops, and then begins to rotate the other way, as if it were an under-shot water-wheel. This can be repeated as often as I like to reverse the position of the magnet, the change of rotation of the wheel showing immediately the way the molecular stream is deflected.

This experiment illustrates the last of the phenomena which time allows me to bring before you, attending the passage of the induction spark through a highly exhausted atmosphere. It will now be naturally asked, What have we learned from the phenomena described and exhibited, and from the explanations that have been proposed? We find in these phenomena confirmation of the modern views of matter and energy. The facts elicited are in harmony with the theory that matter is not continuous but composed of a prodigious number of minute particles, not in mutual contact. The facts also are in full accordance with the kinetic theory of gases—to which I have already referred—and with the conception of heat as a particular kind of energy, expressing itself as a rapid vibratory motion of the particles of matter. This alone would be a lesson of no small value. In science every law, every generalisation, however well established, must constantly be submitted to the ordeal of a comparison with newly-discovered phenomena; and a theory may be pronounced triumphant when it is found to harmonise with and to account for facts which, when it was propounded, were still unrecognised or unexplained.

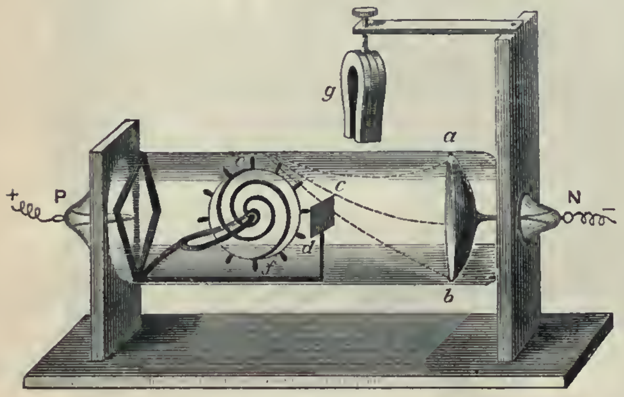

FIG. 19.

But the experiments have shown us more than this: we have been enabled to contemplate matter in a condition hitherto unknown—in a fourth state—as far removed from that of gas as gas is from liquid, where the well-known properties of gases and elastic fluids almost disappear, whilst in their stead are revealed attributes previously masked and unsuspected. In this ultra-gaseous state of matter phenomena are perceived which in the mere gaseous condition are as impossible as in liquids or solids.

I admit that between the gaseous and the ultra-gaseous state there can be traced no sharp boundary; the one merges imperceptibly into the other. It is true also that we cannot see or handle matter in this novel phase. Nor can human or any other kind of organic life conceivable to us penetrate into regions where such ultra-gaseous matter may be supposed to exist. Nevertheless, we are able to observe it and experiment on it, legitimately arguing from the seen to the unseen.

Of the practical applications that may arise out of these researches, it would now be premature to speak. It is rarely given to the discoverer of new facts and new laws to witness their immediate utilisation. The ancients showed a perhaps unconscious sagacity when they selected the olive, one of the slowest growing trees, as the symbol of Minerva, the goddess of Arts and Industry. Nevertheless, I hold that all careful honest research will ultimately, even though in an indirect manner, draw after it, as Bacon said, "whole troops of practical applications."

NOTES

A MEETING of the Executive Committee having charge of the whole arrangements for the approaching visit of the British Association to Sheffield was held the other day. In connection with the Guide Book it was reported that contributions were arranged from Prof. Green, Mr. Arthur Jackson, Mr. [illegible]. Prittain, Mr. G. R. Vine, Mr. J. D. Leader, and others. It is proposed to issue the guide books at 1*s*. each, and they will contain scientific and other information suitable for visitors and residents. Dr. Sorby stated that a number of eminent men from foreign countries, including representatives from Germany, Italy, France, Belgium, the United States, and other parts of the world, had accepted invitations to take part in the meetings in Sheffield. These distinguished visitors will represent different branches of science; and from France the British Association is this year to be honoured, after the lapse of a long period, with the presence of the President of the Academy of Sciences, M. Daubrée. The Mayor (Ald. Ward) is to give a banquet to a number of distinguished guests in the banqueting hall of the Cutlers' Company on Saturday, August 23. A reception is to be given by the Master Cutler and Cutlers' Company, which will take place in the Cutlers' Hall on Thursday, August 21. A *soirée* is to be arranged by the local committee for the Tuesday following, also in the Cutlers' Hall. The arrangements for the excursions are being actively carried out. The Duke of Devonshire has invited a limited number of Members of the Association to a luncheon at Chatsworth. Earl Manners has invited a number of excursionists to luncheon at Thoresby, with the additional offer that they should be driven round the forest and park afterwards. Sir Joseph Whitworth has offered hospitality to a party of excursionists visiting Darley Dale and the district, and a similar offer has been made by Mr. F. C. Armitage, as regards a party exploring Arborlowe. The Rev. A. W. Hamilton-Gell invites a number of excursionists to Stanton-in-Peak, with the promise that they should see Router Rocks and other places of interest. Sir John Lubbock is to be asked to give an address at Arborlowe on the interesting Druidical remains there to be seen. Generally the arrangements were reported to be in a very satisfactory state.

SOME weeks since we stated that a committee had been formed for the purpose of raising a fund for the benefit of the widow and family of the late Mr. W. G. Valentin, F.C.S. We understand that many of the friends and former pupils of this well-known chemist have responded with liberality, but as there may be others whom previous appeals have not reached, we have pleasure in stating that subscriptions will still be received by the hon. treasurer of the fund, Mr. F. W. Bayly, Royal Mint, E.

THE success which attended Mr. Tegetmeier's reprint of Boddaert's "Table des Planches Enluminées," and Mr. Dresser's reproduction of Eversmann's Addenda to Pallas's "Zoographia Rosso-Asiatica," has suggested the organisation of a "Willoughby Society for the Reprinting of scarce Ornithological Works," which has accordingly been formed, with every prospect of success. The annual subscription is 1*l*., and no copies of the works reprinted will be sold. The selection of the works to be reprinted by the Society has been intrusted to a committee consisting of the past and present editors of *The Ibis*, and Tunstall's "Ornithologia Britannica" will be the first work reproduced. Particulars may be obtained from the secretary, F. D. Godman, Esq., 10, Chandos Street, Cavendish Square, W.

THE death is announced of Dr. Johann Karl Friedrich Rosenkranz, Professor of Philosophy at Koenigsberg University. Dr. Rosenkranz published a number of philosophical treatises, and was well known through his excellent edition of the works of Immanuel Kant. He died at the age of seventy-four on June 14.

THE monument of the late eminent botanist, Prof. Alexander Braun, was unveiled on June 17 at the Botanical Gardens of Berlin. The granite pedestal is by Prof. Adler, the bust of the deceased, which is said to be an excellent likeness, by the well-known sculptor Prof. Schaper.

ACCORDING to the resolution passed at the last International Congress of Americanists at Luxemburg in 1877, the city of Brussels will be the meeting-place for this year's (third) congress. It will be held from September 23-26 under the protectorate of the King of the Belgians and the honorary presidency of the Count of Flanders. We have before stated the objects of the Congress, which will again be occupied by the consideration and discussion of a series of questions relating to the history, archæology, anthropology, ethnography, linguistics, and palæography of North and South America.

PROF. VIRCHOW, Dr. Schliemann's companion and coadjutor in the latest excavations in the Troad, has written to the eminent Homeric archæologist, informing him of a concurrence of geological opinion at Berlin in the conclusion that all the building stones, fragments of which the professor brought home from Hissarlik, are of fresh-water formation. This conclusion is thought to be decisive against those who affirm the impossibility of identifying Hissarlik with the Homeric Troy, on the ground that at the time of the great epic war the site must have been covered by the sea.

IN the Paris Academy of Sciences M. Dausse has been elected a Corresponding Member in the Section of Mechanics, in succession to the late General Didion.

THE French Minister of Fine Arts has placed at the disposition of the War Office fourteen cups of Sèvres china to be offered in competition to the societies of carrier-pigeon breeders.

THE *Times* Paris correspondent states that Dr. Krauss, at a scientific meeting at Stuttgart a few days ago, referred to the recent swarms of the *Vanessa cardui* butterfly. A like phenomenon occurred in Piedmont in 1741, 1826, and 1857. This year a swarm passed through Turin on June 2, through Switzerland from the 2nd to the 9th, Alsace, France, and Spain from the 5th to the 10th, and Würtemburg from the 11th to the 21st. Prof. Eimer, of Tübingen, found that eighteen out of nineteen specimens were females full of eggs, and he attributes the march to the search for a place to deposit their eggs; a march directed by their keen scent. Caterpillars have already been found on thistles in the districts visited, and a large number may be looked for.

THE thirty-sixth annual congress of the British Archæological Association is to be begun at Great Yarmouth on August 11, and continue until the 20th, the last three days, commencing on Monday, August 18, being passed at Norwich. Lord Waveney will deliver an inaugural address at the Town Hall, Great Yarmouth, as president of the meeting, on Monday, August 11, and the following days up to Saturday the 16th will be dedicated to a variety of interesting excursions.

IN connection with the celebration of the fiftieth anniversary of the Paris Central School of Arts and Manufactures, the *Gazzetta d'Italia* states that the meeting of engineers connected with the Florentine branch was held on Sunday, and that a banquet was given by the president, Commendatore Prof. Vegni. After dinner those present visited the Workshop Galileo, in which so much is being done for the resuscitation of mechanical art in Florence, with no aid either from Government or the Municipality. Over the door of the workshop is a clock so ingeniously constructed that it has gone now for fourteen months with a loss of only five seconds. A chronograph was exhibited capable of registering the thousandth part of a second, and applicable to the measurement of the velocity of projectiles; a cathetometer capable of measuring heights to the 1,200th of a millimetre, a new electric machine by induction, and a most efficient pneumatic machine, the invention of the eminent Padre Cecchi.

WE daresay most of our readers will be pleased at the result of the motion by Mr. S. Lloyd in the House of Commons, on Tuesday, in favour of appointing a Minister of Commerce and Agriculture. The motion was agreed to by a fair majority, among which were members of both sides of the House. This is a step in the right direction.

THE Giffard captive balloon has begun its series of night ascents by an experimental trip, which was made on June 30 with great success. The court of the Tuileries was lighted by ten Jablochkoff lamps. It is proposed to carry an electric lamp on the car if the sixty portable Bunsen elements which are in preparation can be carried without inconveniencing passengers. Captive ballooning is making its way in foreign lands. A captive balloon is being fitted up in one of the places of resort round New York; the balance for registering the levitation has been constructed in Philadelphia. It can register accurately 10,000 pounds, and is built for sustaining 25,000.

THE Paris Exhibition of Sciences Applied to Industry will be opened on the 24th inst. The preparations are being made with great activity in the Palais de l'Industrie. M. Jules Simon, the President of the Council, and M. Nicol, the Director, had an interview, on June 29, with the President of the Republic, to suggest a series of measures intended to promote the success of the exhibition.

MR. F. W. MOORE, eldest son of the late Dr. Moore, has been appointed Curator of the Botanic Gardens, Glasnevin, Dublin. Mr. Moore has been for some time curator of the College Botanic Garden, Dublin.

A SELECT Committee of the House of Commons, of which Mr. A. Pell was chairman, have concluded their consideration of the Bill promoted by the Liverpool Corporation, to give power to adopt and supply for public and private purposes lighting by electricity. The committee had intimated their decision to pass the Bill if amendments were made in the preamble, the effect of which would be to limit the power of the Corporation to making a scientific experiment, and not allow them to make it a commercial undertaking for purposes of profit, or to compete with the gas company. Amendments were proposed by the Corporation in this direction, and the committee passed the Bill.

IT is stated that the Council of India, despairing of obtaining the repeatedly asked-for assistance of the Imperial Government towards defraying the cost of the India Museum, have decided to break it up and to distribute the collections between the British and South Kensington Museums and Kew.

FROM the report on the forests and plantations in the Island of Mauritius for 1878 we learn that many of the trees which were introduced from India a few years ago have thriven beyond expectation and have in some instances already reached the size of useful timber trees. Among those which have done best are mahogany, teak, and eucalyptus. The last named (*E. calophyllus*) is found to grow with remarkable vigour, and produces fertile seed at a very early age. The severe hurricanes which sweep over the island commit great devastation among the plantations of eucalyptus and other fast-growing trees, and the Government this season intend to plant out a large number of the young gum trees to be grown as large as bushes. In this form they are expected to be able to withstand the force of the wind, and form a screen for the protection of young plantations of timber trees.

On Saturday the Geologists' Association have an excursion to Tunbridge Wells and Crowborough Beacon. On Monday, July 21, and five following days the same society intend to have an outing in the neighbourhood of Ledbury; the Malvern Hills and Woolhope Valley being included in the programme.

In the *Journal de Physique* for June M. Cornu gives an account of his spectroscope designed for observation of ultra-violet radiations. It resembles the common two-prism spectroscope, except in the materials employed, the ordinary materials, crown-glass and flint-glass, absorbing ultra-violet radiations at least from the line O, *i.e.*, from wave-length = 340 millionths of a millimetre. M. Cornu uses quartz for the prisms, and the objective of the collimator (as also of the telescope) is made achromatic; it consists of a biconvex lens of quartz and a divergent plane concave lens of Iceland spar, both cut perpendicularly to the optic axis.

Phosphoric acid has the property of hindering the precipitation of albumen by tannin, but is without action on gelatine. M. Ador lately had the curiosity to try its effect in the tanning of skins, starting with the idea that the pores of skin would remain more open and that the solution of tannin would thus more rapidly coagulate the gelatinous substances, within the skin, producing a more rapid tanning. His experiments, both in the laboratory and on a large scale, are described in the *Moniteur Scientifique* for June. They show that the anticipated effect was realised, and that it allows of the use of a much stronger juice; but there is danger of a loss of weight if the liquids be agitated, by reason of coagulation, outside of the tissues, of a certain quantity of albuminoid principles dissolved by the phosphoric acid, and removed from the skin. He recommends manufacturers to experiment further in the same direction.

M. Robin, the anatomist, who is the only member of the Academy of Sciences who is also in the French Senate, has proposed a bill for instituting an inquiry into the means of increasing the fish production of the French rivers.

In the aëronautical ascent made at Rouen, referred to in our last number, the altitude was 1,200, not 12,000, metres.

The New York correspondent of the *Daily News* telegraphs that Mr. Edison states that since the patents for his electric light were issued he has improved the standard meter for measuring the electricity fed to the burners, and has perfected a method of insulating and conveying the wires from the generating stations to the houses of the consumers. He is satisfied that this generator cannot be improved. 94 per cent., it is said, of horse-power is set free in the electric current, and 82 is delivered in the wire outside of the machine. Eight-ninths of the current is used for the light, and one-ninth is lost in the machine. Mr. Edison's latest experiments give seven gas jets per horse-power, and he expects to increase the number to ten. He says the platinum burner is a settled thing; but, so long as he sees his way to getting more light cut of the horse-power, he will continue his experiments. He expects to perfect his experiments within four weeks.

A catastrophe similar to the one which was happily averted at Teplitz is now feared at the well-known watering-place of Baden, near Vienna. An official investigation committee has been formed, comprising several members of the Geologische Reichsanstalt, and has already begun examining the springs threatened with exhaustion.

We continue to receive the numbers of the *Revista de Canarias*, to which we referred some weeks since. We trust it will meet with the support it deserves, as it is evidently making honest attempts to spread a knowledge and cultivate a taste for science among the inhabitants of the favoured islands. The last number, June 8, contains an article on the Palæontology of the Canaries, by Miguel M. y La-Roche; one on the Hygiene of the Potato, by Lorenzo Lapuyade; another on Primary Instruction in the Canaries, by Juan de la Puerta Causeco.

A violent earthquake is reported from Agram on June 21 at 8.55 A.M., which was repeated on the 22nd at 1.42 A.M. On both occasions the phenomenon consisted of several shocks proceeding in the direction from west to east.

We learn from a Queensland paper that Mr. Walter Hill has been sent on a tour of inspection to Great Sandy, or Fraser, Island, a large irregular-shaped island lying off the coast to the north of the twenty-sixth parallel of south latitude, where it is reported that some valuable timbers flourish, notably the kaurie pine. For some time past the curator of the Botanical Gardens has been giving his attention to the propagation of some of the most valuable timbers indigenous to the colony, and at one place he has formed a nursery of red cedar trees, in which 30,000 plants have been successfully reared and are now all in a flourishing condition. It is believed that a part of Mr. Hill's mission to Fraser Island is to look for suitable sites for arboriculture, with the view of utilising the large number of red cedar plants he has reared. The red cedar takes from sixty to one hundred years to attain its best development, and this care for distant posterity is probably due to thoughtfulness on the part of the authorities who view with alarm the wholesale devastation and waste of the timber which from time to time take place in the colony. It is said that there are yet plenty of cedar trees in the Queensland forests, but quite recently several million feet of this timber were swept out to sea in consequence of a fresh in the Mossman, Daintree, and Johnston rivers.

Careful statistics have been taken in Paris of the cases of rabies observed in 1878. The total number of cases reported to the Prefecture has been 440 dogs, 68 bitches, and 3 cats. Out of these 511 cases 390 were biting rabies. The number of wounds inflicted on persons was 103, and the number of deaths 30—about 1 to 3. This is the same proportion as resulted from previous inquiries. Almost all these cases have been reported from Paris out of a population of 2,000,000. The number of animals which have been bitten by mad dogs is 342 dogs and 24 cats. 234 animals were taken to the veterinary school of Alfort either for autopsy or for inspection.

It is stated that in consequence of the auriferous indications in the Cooktown district, the Queensland Government will offer a reward of 5,000*l*. to stimulate the discovery of a gold-field rich enough to pay the cost of working.

Part V. just issued of the past *Transactions* of the Leicester Literary and Philosophical Society contains the papers read from June, 1850, to June, 1855.

The additions to the Zoological Society's Gardens during the past week include a Grand Galago (*Galago crassicaudata*) from East Africa, presented by Mr. W. Jenkins; a Grivet Monkey (*Cercopithecus griseo-viridis*) from North-East Africa, presented by Mr. R. M. Courage; a Rhesus Monkey (*Macacus erythræus*) from India, presented by Mr. Jas. Bartle; a Puma (*Felis concolor*) from Buenos Ayres, presented by Lord Lilford, F.Z.S.; a Blue-eyed Cockatoo (*Cacatua ophthalmica*) from the Solomon Islands, presented by Lieut.-Col. Arbuthnot, 14th Hussars; a Common Boa (*Boa constrictor*) from South America, presented by Dr. A. Stradling; a Black-faced Spider Monkey (*Ateles ater*), three Red-billed Tree Ducks (*Dendrocygna autumnalis*) from South America, a Collared Fruit Bat (*Cynonycteris collaris*), captured in the Red Sea, two White Storks (*Ciconia alba*), a Common Whimbrel (*Numenius phæopus*), European, a Reticulated Python (*Python reticulatus*) from Manilla, purchased; an Axis Deer (*Cervus axis*), born in the Gardens.

THE GENESIS AND MIGRATIONS OF PLANTS

SUCH is the title of a paper, in a recent *Princetown Review*, by Prof. Dawson, whose intention in writing has been to place clearly and concisely before his readers the facts, as he interprets them, connected with the fossil floras of the Arctic and North American regions. The necessity to do so became apparent, he states, from the time that Heer described the cretaceous[1] Vancouver Island flora as miocene, and yet more when the Devonian Bear Island flora was described as carboniferous. The present publication, however, was immediately induced by Saporta's very remarkable essay on the northern origin of plant species and Hooker's latest anniversary address to the Royal Society.

The Professor commences the present essay by recalling that Asa Gray had, as early as 1867, suggested that the related floras of North America and Eastern Asia had a common northern origin; and that in 1872 he further developed this theory, embracing in it the work of Heer and Lesquereux on the tertiary floras.

He then proceeds:—

"Between 1860 and 1870 the writer was engaged in working out all that could be learned of the Devonian plants of Eastern America, the oldest known flora of any richness, and which consists almost exclusively of gigantic, and to us grotesque, representatives of the club mosses, ferns, and mares'-tales, with some trees allied to the cycads and pines. In this pursuit nearly all the more important localities were visited, and access was had to the large collections of Prof. Hall and Prof. Newberry in New York and Ohio, and to those made in the remarkable plant-bearing beds of New Brunswick by Messrs. Matthew and Hartt. In the progress of these researches, which developed an unexpectedly rich assemblage of species, the northern origin of this old flora seemed to be established by its earlier culmination in the north-east, in connection with the growth of the American land to the southward, which took place after the great upper silurian subsidence, by elevations beginning in the north while those portions of the continent to the south-west still remained under the sea.

"When, in 1870, the labours of those ten years were brought before the Royal Society of London in the Bakerian lecture of that year, and in a memoir illustrating no less than one hundred and twenty-five species of plants older than the great carboniferous system, these deductions were stated in connection with the conclusions of Hall, Logan, and Dana, as to the distributions of sediment along the north-east side of the American continent, and the anticipation was hazarded that the oldest Palæozoic floras would be discovered to the north of Newfoundland. Mention was also made of the apparent earlier and more opious birth of the Devonian flora in America than in Europe, a fact which is itself connected with the greater northward extension of this continent."

The memoir was not published by the Royal Society, and some little disappointment, he says, was thereby occasioned, but it appeared shortly after, although in a less perfect form.[2]

In the next place he contends that Heer was in error in supposing that the Bear Island plants are of carboniferous age, and attributes to Heer the responsibility of having led other European geologists to infer that the whole group of beds from the Hamilton to the Chemung were carboniferous, although they underlie the oldest beds of that stage and contain a Devonian fauna. He continues:—

"In 1872 I addressed a note to the Geological Society of London on the subject of the so-called 'Ursa stage' of Heer showing that though it contained some forms not known at so early a date in temperate Europe, it was clearly Devonian when tested by North American standards; but that in this high latitude, in which, for reasons stated in the report above referred to, I believed the Devonian plants to have originated, there might be an intermixture of the two floras. But such a mixed group should in that latitude be referred to a lower horizon than if found in temperate regions. In the discussion of these papers, both Sir C. Lyell and Dr. Carruthers argued that the Bear Island flora is truly Devonian.

"Passing over the comparatively poor flora of the earlier mesozoic, consisting largely of cycads, pines, and ferns, and as yet little known in the Arctic, though represented, according to Heer, by the supposed Jurassic flora of Cape Boheman, we find, especially at Komé and Atané in Greenland, an interesting occurrence of those earliest precursors of the truly modern forms of plants which appear in the Cretaceous, the period of the English Chalk and of the New Jersey greenlands. There are two plant-groups of this age in Greenland; one, that of Komé, consists almost entirely of ferns, cycads, and pines, and is of decidedly mesozoic aspect. This is called lower cretaceous. The other, that of Atané, holds remains of many modern temperate genera, as *Populus*, *Myrica*, *Ficus*, *Sassafras*, and *Magnolia*. This is regarded as upper cretaceous. Resting upon these upper cretaceous beds, without the intervention of any other formation,[1] are beds rich in plants of much more modern appearance, and referred by Heer to the miocene period, a reference warranted by comparison with the tertian plants of Europe, but, as we shall see, not with those of America. Still farther north this so-called miocene assemblage of plants appears in Spitzbergen and Grinnell Land; but there, owing to the predominence of trees allied to the spruces, it has a decidedly more boreal character than in Greenland, as might be anticipated from its nearer approach to the pole.[2]

"If now we turn to the cretaceons and tertiary floras of Western America, as described by Lesquereux, Newberry, and others, we find in the lowest cretaceous rocks there known—those of the Dakota group—which may be in the lower part of the middle cretaceous, a series of plants[3] essentially similar to those of the so-called upper cretaceous of Greenland. They occur in beds indicating land and fresh-water conditions as prevalent at the time over great areas of the interior of America. But overlying this plant-bearing formation we have an oceanic limestone (the Niobrara), corresponding in many respects to the European chalk, and extending far north into the British territory,[4] indicating that the land of the lower cretaceous was replaced by a vast Mediterranean Sea, filled with warm water from the equatorial currents, and not invaded by cold waters from the north. This is succeeded by thick upper cretaceous deposits of clay and sandstone, with marine remains, though very sparsely distributed; and these show that further subsidence or denudation in the north had opened a way for the arctic currents, killing out the warm-water animals of the Niobrara group, and filling up the Mediterranean of that period. Of the flora of these upper cretaceous periods, which must have been very long, we know nothing in the interior regions; but on the coast of British Columbia we have the remarkable cretaceous coal-field of Vancouver's Island, which holds the remains of plants of modern genera, and indeed of almost as modern aspect as those of the so-called miocene of Greenland. They indicate, however, a warmer climate as then prevalent on the Pacific coast, and in this respect correspond with a peculiar transition flora, intermediate between the cretaceous and eocene or earliest tertiary of the interior regions, and which is described by Lesquereux as the lower lignitic.

"Immediately above these upper cretaceous beds, we have the great lignite tertiary of the west—the Laramie group of recent American reports—abounding in fossil plants, at one time regarded as miocene, but now known to be lower eocene, though extending upward toward the miocene age.[5] These beds, with their characteristic plants, have been traced into the British territory north of the forty-ninth parallel, and it has been shown that their fossils are identical with those of the McKenzie River Valley, described by Heer as miocene, and probably also with those of Alaska, referred to the same age.[6] Now this truly eocene flora of the temperate and northern parts of America has so many species in common with that called miocene in Greenland, that its identity can scarcely be doubted. These facts have led to scepticism as to the miocene age of the upper plant-bearing beds of Greenland, and more especially Mr. J. Starkie Gardner has ably argued, from comparison with the eocene flora of England and other considerations, that they are really of that earlier date.[7]

"In looking at this question, we may fairly assume that no

[1] Lesquereux considers this flora to be eocene.

[6] G. M. Dawson, "Report on the Geology of the Forty-ninth Parallel," where full details on these points may be found.

[7] *Nature*, vol. xviii. p. 124.

conceivable conditions of climate could permit the vegetation of the neighbourhood of Disco in Greenland to be identical with that of Colorado and Missouri, at a time when little difference of level existed in the two regions. Either the southern flora migrated north in consequence of a greater amelioration of climate, or the northern flora moved southward as the climate became colder. The same argument, as Gardner has ably shown, applies to the similarity of the tertiary plants of temperate Europe to those of Greenland. If Greenland required a temperature of about 50°, as Heer calculates, to maintain its 'miocene' flora, the temperature of England must have been at least 70°, and that of the South-western States still warmer."

The author then speculates upon the former migrations of plants, and although he does not assign, like Saporta, an unvarying north and south direction, he believes that in most instances these were the lines upon which they moved. He also places a cold period between the middle cretaceous (upper cretaceous of Atané, Heer) and the lower eocene (Greenland miocene, Heer), which had not been previously noticed.

We would here remark that there is, in like manner, evidence of a cool period at the base of the English eocene. Either one relatively cool period existed at the close of the upper cretaceous of America, and another at the base of the English eocene, or else too great an age is assigned to the American series. The latter supposition is supported by Lesquereux's researches. The beds showing the more temperate conditions on the two continents are either contemporaneous or else a geological interval exists between them. Much more evidence is required before the correlation of the American and European cretaceous and tertiary rocks can be finally determined, and it is satisfactory to know that Dr. Hayden is collecting evidence on the subject.

The lower eocene flora of Greenland "established itself in Greenland, and probably all around the arctic circle, in the warm period of the earliest eocene, and as the climate of the northern hemisphere became gradually reduced from that time to the end of the pliocene, it marched on over both continents to the southward, chased behind by the modern arctic flora, and eventually by the frost and snow of the glacial age. This history may admit of correction in details; but so far as present knowledge extends it is in the main not far from the truth."

Space does not permit us to reprint the pages devoted to the various theories that have been put forward to account for former vicissitudes of climate. While allowing due weight to Croll's ingenious and well known theories, and to the larger proportion in the past of carbonic dioxide, he nevertheless is convinced of the sufficiency of the Lyellian theory of former altered distribution of land and water to account for all the facts hitherto observed.

The author conceives, however, that in some recent publications the Lyellian theory has been misconceived, but this is not exactly the case. What he here terms the Lyellian theory was really shared by many contemporary writers on physical geography, and is, that when land surfaces are aggregated round the equator and the polar oceans are wide and open, a hot period results, and that the reverse distribution induces cold, thus giving to land the heating power. The more recent theory is a modification of this, requiring masses of water, warmed under the equator, to circulate, unchilled by polar currents, and the polar oceans to be dry or else more or less closed in by land. This view he adopts.

"If North Greenland were submerged, and low land reaching to the south terminated at Disco, and if from any cause either the cold currents of Baffin's Bay were arrested, or additional warm water thrown into the North Atlantic by the Gulf Stream, there is nothing to prevent a mean temperature of 45° Fahrenheit from prevailing at Disco; and the estimate ordinarily formed of the requirements of its extinct floras is 50°,[1] which is probably above rather than below the actual temperature required."

Professor Dawson believes that to whatever causes the cold periods may be traced, they drove the warm temperate flora to the south, unless protected in insular spots by warm currents, and that on the return of warmth the plants would return northward.

"If, however, our modern flora is thus one that has returned from the south, this would account for its poverty in species as compared with those of the early tertiary. Groups of plants descending from the north have been rich and varied. Returning from the south they are like the shattered remains of a beaten army. This at least has been the case with such retreating floras as those of the lower carboniferous, the permian, and the Jurassic, and possibly that of the lower eocene of Europe."

The great stretch north and south of the American continent favoured these migrations, and "is also connected with the interesting fact that, when new floras are entering from the arctic regions, they appear earlier in America than in Europe; and that in times when old floras are retreating from the south, old genera and species linger longer in America. Thus, in the Devonian and cretaceous new forms of those periods appear in America long before they are recognized in Europe, and in the modern epoch forms that would be regarded in Europe as miocene still exist. Much confusion in reasoning as to the geological ages of the fossil floras has arisen from want of attention to this circumstance."

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

In reply to a question in the House of Lords the other day the Duke of Richmond and Gordon stated that it was only in 1875 that it was decided to add agriculture to the syllabus of the Science and Art Department. At the first examination in May, 1876, there were only 150 candidates. By the following year 72 classes had been established, and the number of candidates rose to 800. In 1878 the classes had increased to 91, and the candidates for examination to 1,265, and this year the number of classes had reached 147; the number of persons under instruction was 2,839, of whom 2,193 came up for examination. Prof. Tanner reported that the results of the examination were very satisfactory. Fifty selected teachers, it was stated, had been brought up to London to undergo a course of training at the expense of the department.

The two silver medals which are annually given by the Royal Geographical Society to those candidates whom the examiners deem to be most proficient in geography at the Cambridge Local Examinations have this year been awarded as follows:—Physical Geography, J. R. Davis; Political Geography, Miss Helen Jones. This, we believe, is the first occasion on which a medal has been awarded to a lady.

The professors of the Paris Museum of Natural History having to present to the Minister of Public Instruction the names of two candidates for the lectureship of Comparative Anatomy, vacated by the death of M. Paul Gervais, have selected M. Georges Pouchet for their first candidate, and M. Jourdain for the second. The appointment of the former is quite certain.

The number of students at the German Universities during the winter semester 1878-9 was 18,770. Berlin stands at the top of the list with 3,213, while Rostock had only 161.

SOCIETIES AND ACADEMIES

London

Royal Society, June 19.—"Relations between the Atomic Weights and certain Physical Properties (Melting and Boiling Points and Heats of Formation) of Elements and Compounds." By Thomas Carnelly, D.Sc., Assistant Lecturer on Chemistry in Owens College, Manchester. Communicated by Prof. H. E. Roscoe, F.R.S.

Anthropological Institute, June 24.—Mr. John Evans, F.R.S., vice-president, in the chair.—The election of the following new Members was announced:—Mr. F. Du Cane Godman, F.L.S., F.Z.S., and Mr. Percy Cotterill Wheeler, Bengal Civil Service.—Prof. W. H. Flower, F.R.S., read a paper on the osteology of the natives of the Andaman Islands. There are few people whose physical characters offer a more interesting subject for investigation to the anthropologist than the native inhabitants of the Andaman Islands. Purity of type, due to freedom from mixture with other races for an extremely long period, owing to their isolated position and their inveterate hostility to all intruders on their shores, and exemplified in the uniformity of their physical characters, is to be found among them, perhaps in a more complete degree than in any other group of mankind. The type, moreover, is an extremely peculiar one, presenting a combination of characters not found in any race of which we have at present materials for a satisfactory comparison. It is, indeed, probable that the more or less mixed and now scattered fragments of Negrito population, found in the interior of various islands of the Indo-Malayan Archipelago, and even upon some parts of the

mainland of Asia, may have been derived from the same stock, but the special interest of the Andamanese consists in the fact that they alone of the diminutive black, woolly-haired people, occupy the whole of the small islands, on which their ancestors have dwelt from time immemorial, or rather did so occupy them until the coming upon them of the English in 1857. The materials upon which the observations contained in the memoir are based, are far more complete than any wh'ch have hitherto been brought together, consisting of nineteen skeletons and nearly thirty skulls. The skeletons indicate an average height of 4 feet 9 inches in the males, and 4 feet 6 inches in the females, thus showing that they belong to some of the smallest of known races. The skulls all belong to what is known as the brachycephalic or round-headed type, having an average cephalic index (or proportion of breadth to length) of 82. The forehead is broad and flat, without any projection over the orbits. The nose is narrow and the jaws less prominent than in the other black races. The proportionate length of the various bones of the limbs differ greatly from the European standard, but resemble those of the negro. With the Australian the Andamanese have very little affinity, the smooth hair of the former entirely separating them, independently of cranial characters, as dolichocephaly (or long-headedness) strongly pronounced brow ridges, low orbital index, wide nasal aperture, great prognathism, &c. It is to the other woolly-haired races that we must naturally turn in endeavouring to find their nearest relatives. The Papuans and inhabitants of the Melanesian Islands differ from them greatly in their principal cranial characters, especially in the great height and narrowness of the skull. The Tasmanians had wider heads, but their facial characters were more like those of the Australians, and therefore widely different from the Andamanese. The African negroes, again, are almost all dolichocephalic, and as a general rule are extremely prognathous, and strongly platyrhine or broad-nosed. Many of them, however, have the smooth brow and round orbits seen in the Andamanese, and not generally met with in the true oceanic negroes. The natives of the Andaman Islands, with whom may probably be associated the less known Aetas of the Philippines, the Semangs of the Malay Peninsula, thus constitute a race apart, to which the name Negrito may properly be applied. At first sight, they appear in their craniological characters to present little affinity to either of the other woolly-haired races, but it is probable that they represent a small or infantile type of the same primary group, as nearly all the characters by which they differ from the other negroes—the smaller size, smoother, and more globular heads, absence of supraorbital prominences, rounder orbits, and less projecting jaws, are those which we find in the younger individuals of a species, as compared with the older, or in the smaller species of a natural group as compared with the larger. It is very possible, but this is purely hypothetical, that the Andamanese, whose geographical position is almost midway between either extremes of the range of the woolly-haired races, may be the unchanged or little-modified representatives of a primitive type, from which the African negroes on the one hand, and the Oceanic negroes on the other, have taken their origin, and hence everything connected with their history or structure becomes of the greatest interest to the anthropologists.—The following papers were also read:—On palæolithic implements from the Valley of the Brent, by Mr. Worthington G. Smith; and Portstewart and other flint factories of the north of Ireland, by W. J. Knowles.

Physical Society, June 21.—An extra meeting of this Society was held on the above date at Cooper's Hill Indian Engineering College, on the invitation of Col. Chesney, R.E., Lord Rosse occupying the chair.—Prof. Unwin, of the College, read a paper on experiments relating to the friction of fluids on solid surfaces against which they rub. It has long been known that a board dragged through water suffers a resistance varying in some way as the square of the velocity; that a stream takes a uniform motion at such a velocity that the component of the weight of the water down its inclined bed is balanced by the frictional drag on the bottom. The fluid in the neighbourhood of the stream is known not to move as a solid mass, the centre moving faster than the sides, and the different fluid layers rub against each other. The adhesion of the fluid to the solid against which it moves also gives rise to a sliding or rubbing action. Our knowledge of the subject has hitherto been gained from observations on pipes, streams, and from the experiments of the late Mr. Froude with a plank of wood drawn through the water of a canal. It is desirable to have a set of laboratory experiments, however, in which the conditions can be varied more than can be done by such methods, and for this purpose the author had designed a special apparatus. In Mr. Froude's experiments there was a practically unlimited mass of water and a definitely limited extent of solid surface, and his results are not free from certain anomalies. The author thought it might be instructive to try the other case of a limited mass of water and a virtually unlimited surface. A disk in rotation gives such a surface. In some respects a cylinder would (as suggested by Prof. Ayrton) be the simplest to treat theoretically, but there are experimental difficulties in its way. The apparatus of the author consists of a metal disk rotated on a vertical axis in a vessel of water, and the problem is to determine its resistance to rotation, since this will be equivalent to the water-friction upon it. Within the outer vessel is placed a thin copper chamber, the diameter of which is unalterable, but the depth is variable at pleasure. The disk is placed concentrically inside this chamber, where there are two cheese-shaped masses of water, one above and one below the disk, which are dragged into rotation next the disk, and retarded next the sides of the pan. The couple required to rotate the disks is equal to the couple exerted by the disk or the fluid when the motion is uniform; hence the tendency of the chamber to rotate is measured, by suspending the latter from three wires in a manner similar to the bifilar suspension of magnets. An index marks whether it rotates or not on a graduated scale; and a weight suspended by a cord measures the force required to keep the index at zero. Let M be the moment of the frictional resistance of the disk, N the number of revolutions per second. Then $M = C N^x$, where C and X are constants. The author has obtained a number of results which are, however, not yet ready for publication. He mentioned, however, that a rough cast-iron disk has a frictional resistance almost exactly as the square of the velocity, whereas a turned brass disk gave a value of x decidedly less than 2. The resistance is a little greater when the mass of water is larger. These results were calculated for a speed of 10 feet per second. The author hopes to try the effect of temperature, &c., on fluid friction and viscous as well as thin fluids. Prof. Unwin also exhibited a piece of apparatus with which he hopes to study the stress of rivetted plates under shear, by means of elastic substances such as caoutchouc. He purposes to stretch the caoutchouc and photograph the appearance of stress rivetted lines upon it.—Lieut. G. S. Clark, R.E., explained the process invented by Prof. McLeod and himself for determining the absolute pitch of tuning-forks. Unlike other methods this is an optical one, and consists in arranging the tuning-fork to vibrate in front of a rotating drum whose periphery is marked with dots or fine lines at equal intervals. A microscope was arranged to comprise in its field of view the edge of the fork and several of the intervals on the drum, so that when the drum was rotated at a rate which made the speed of an interval equal to the period of the fork, a set of prominences or waves, in width equal to an interval, were visible; the body of the wave being caused by the advance and recession of the fork in its vibration. The rotation of the drum was regulated by an air-regulator devised by Prof. Unwin, the observer himself quickening or slowing the drum so as to keep the prominences steady. The time was beat by an electric clock designed by Prof. McLeod. An aniline glass pen was used to mark the beginning and end of the period of observation on the drum. A counter was also employed to give the number of revolutions. The pen and counter were actuated by electricity through the medium of a key. In these experiments a König fork giving 256 vibrations per second correct at 16°·1 C., was tested, and found to give 256·2966 vibrations per second. Frequent bowing did not alter the phase. Fixing the fork rigidly, as in a vice, did so. The temperature coefficient for König's forks (·00011 for each degree Centigrade) was confirmed by these experiments. Forks of different octaves were compared; audible beats could be counted, and modifications of Lesage's figures seen. This optical method is preferable to audible ones, because of its independence of the ear and the fact that nothing is attached to the fork itself. Prof. Guthrie inquired if the periods of the forks had been found to alter through use or magnetisation. The author said that he had not yet tested these points. Prof. McLeod instanced an old König fork which was correct at 16°·1 C., requiring now a temperature of 25° C. to make it so. Lord Rosse suggested the use of the regulators employed with equatorial clocks to keep the rotation of the drum steady. Capt. Abney inquired if a difference of vibration had been detected between the beginning and end of a series of observations. None had been certainly observed.—Prof. Macleod then described an electric clock used in the foregoing experiments. The zinc and

steel compensating pendulum moved by its own gravity, but at each beat made and broke a battery circuit by means of two bent springs, one on either side. The current passing through an electro-magnet, detained a bent lever until the pendulum swung to the other contact. By this contrivance time was marked. Prof. Macleod found that platinum contacts frequently stuck together in these experiments; but this defect had been cured by the use of a liquid shunt of dilute sulphuric acid, which destroyed the extra current. This remedy had been suggested to him by Lord Rayleigh. Prof. Macleod demonstrated the complete success of this device, which acts as well as a condenser shunt. He had also observed a curious effect with these liquid shunts, which as yet he could not explain. Two shunts having the same acid in both were employed, one shunting the extra current from four Daniell cells, and one that from two Daniell cells. The first showed evolution of H and O gas, the platinum electrodes being unaffected. The second showed no evolution of gas, but one platinum plate was dissolved away and deposited in a black powder on the other. He also exhibited a new cell formed of zinc and mercury plates, with zincic-iodide solution and mercurous chloride salt. Red iodide of mercury is formed at the negative electrode. The E M F is $\frac{7}{10}$ths of a Daniell cell, but the internal resistance very low and the cell very constant; while there is no local action. Prof. Guthrie suggested that the extra current was really a succession of sparks; the platinum might be carried bodily over from one electrode to the other. Mr. F. H. Varley stated that Mr. F. Higgins had observed a similar effect with carbon electrodes in a voltameter, one carbon falling away into a fine powder, and due perhaps to the disintegrating action of liberated gases. He had also himself seen a platinum wire in contact with a carbon one eaten thin and drawn into very fine silky pens, while the carbon was stained blue, although the current passing was of low tension. Mr. Chandler Roberts suggested that perhaps a hydride of platinum was formed in the case mentioned by Prof. Macleod. Prof. Guthrie suggested experiments with fluorescent liquid shunts in the dark.—Mr. J. W. Clark then described some experiments on the surface tension of sulphurous anhydride, sealed in a capillary tube within a second tube, containing the same substance. He found that at low temperatures the level of the liquid is lower in the narrow than in the wide tube. As the temperature rises the meniscus in the narrow tube descends till about 156° Fahr.; it is level with that of the wider tube, both surfaces being slightly concave. Above this temperature the surfaces become plane, then convex, the level in the wide tube becoming higher than that in the narrow one. These experiments are being continued, and Mr. Clark's other results will be communicated to the Society later on.—Prof. Guthrie proposed a vote of thanks to Col. Chesney.

PARIS

Academy of Sciences, June 30.—M. Daubrée in the chair.—The following papers were read:—On the chemical constitution of alkaline amalgams, by M. Berthelot. He shows that the relative affinities of the two alkaline metals for oxygen are inverted in their amalgams. This explains the singular anomaly discovered by MM. Kraut and Topp, viz., the displacement of potassium in dissolved potash by amalgamated sodium, producing the crystallised amalgam $Hg_{24}K$. The displacement is the necessary consequence of the greater loss of energy undergone by the potassium in the formation of the amalgam.—On a peculiarity of an experiment of Gay Lussac and Thenard, by M. Debray. The experiment is that in which hydrated potash or soda in vapour are passed over an excess of well cleaned iron in a highly heated gun-barrel. Hydrogen and vapour of potassium or sodium are liberated, the oxygen being fixed in part of the iron. Gay Lussac and Thenard noticed, without explaining, that the fixation was chiefly on the metal in the part exterior to the furnace, and therefore less hot. This M. Debray attributes to the presence of vapour of the metal and of hydrogen remaining in the apparatus. From experiments by M. Sainte-Claire Deville, it may be deduced that if a mass of iron incompletely oxidised, and having its different parts at variable temperatures, be in a more or less dense atmosphere of hydrogen, the oxygen will quit the hotter parts where it was originally fixed, and go to the cooler. M. Debray illustrates the phenomena by an experiment.—Spectral examination of ytterbine, by M. Lecoq de Boisbaudran. He gives the approximate position and form of the bands, grouped chiefly between the solar lines D and F, of which the spectrum is composed.—M. Dausse was elected Correspondent in Mechanics in room of the late General Didion.—On atmospheric waves, by M. Bouquet de la Grye. This relates to the results of some 15,000 observations of barometric height, and direction and velocity of the winds, at Brest. The numbers given as showing the maximum influence of solar and lunar action prove the greatness of this action and the impossibility of making serious predictions of weather before the atmospheric laws dependent thereon have been studied.—On the nature of the soil of the Isthmus of Gabes and the Chotts, by M. Roudaire. He gives a summary of his observations (some of which have been formerly referred to). His collections contain about 300 plant species and 120 animal, several new; he has also some 500 geological specimens, results of twenty-two borings, daily observations of atmospheric pressure, temperature, hygrometry, the wind, &c.—On Stokes's law; reply to M. Becquerel, by M. Lamansky.—On the dissociation of sulphydrate of ammonium, by MM. Engel and Moitessier. They prove that sulphuretted hydrogen and ammonia do not combine in equal volumes at 50°, and that the supposed vapour of sulphydrate of ammonium is merely a mixture of two gases.—Action of phtalic anhydride on naphtaline in presence of chloride of aluminium, by MM. Ador and Crafts.—On the ashes and lava of the recent eruption of Etna, by M. Cossa. The very fine blackish-grey ash is formed of fragments of crystals of triclinic felspar, augite, small grains of magnetite, and a large number of variously coloured splinters of glass. The lava is formed in great part of large crystals of triclinic felspar disseminated porphyrically in a microcrystalline magma, formed of small crystals of the same felspar, augite, magnetite, and a little greyish vitreous matter. The phenomena (in M. Cossa's opinion) tell against the hypothesis of pre-existence in the solid state of the crystalline elements in lava vomited by volcanoes.—New researches on development of the embryonal sac in angiospermous phanerogams, by M. Vesque.—On a new substance of the epidermis, and on the process of keratinisation of the epidermic coat, by M. Ranvier. The new substance, found in the form of drops in cells of the epidermis, and rapidly colourable red with carmine, he calls *eleidine;* it plays an important *rôle* in keratinisation of the epidermis.—On the structure of broad ligaments, by M. Guérin.—On the state of glandular cells of the submaxillary after prolonged excitation of the chorda tympani, by MM. Arloing and Renaut. He concludes that these cells have a proper individuality, and are not embryonal forms of muciparous cells.—Forage in shocks of sheaves, by M. Duplessis. Green forage may be transformed into hay, in rainy weather, by arranging in shocks, and this transformation takes place more surely and economically than by the old method in the same circumstances.—On the ancient roads of the Sahara, by M. Berlioux. Some old inscriptions have been discovered by the German expedition in the Libyan Desert, on the route the author had indicated as probably a Roman road at one time.

RECENT PUBLICATIONS ON GALILEO'S TRIAL BEFORE THE INQUISITION

Galileo Galilei and the Roman Curia, from Authentic Sources. By Karl von Gebler. Translated with the Sanction of the Author by Mrs. George Sturge. (London: C. Kegan Paul and Co., 1879.)

Der Process Galilei's und die Jesuiten. Von Dr. F. H. Reusch, Professor an der Universität in Bonn. (Bonn, 1879.)

La Question de Galilée: les Faits et les Conséquences. Par Henri de l'Epinois. (Paris et Bruxelles, 1878.)

Encore Galilée! Polémique—Histoire—Philosophie. Par le P. Eugène Desjardins, de la Compagnie de Jésus. Seconde Édition. (Paris, 1877.)

IN presenting us with an English translation of Karl v. Gebler's "Galileo," Mrs. Sturge has conferred an unquestionable boon on those who, without caring to pursue the subject in Continental publications, wish to obtain a fairly complete view of the relations between the Florentine astronomer and the authorities of the Roman Church, as seen in the light of the most recent researches. The original,[1] which appeared in 1876, was chiefly remarkable for its happy selection of just so much documentary and collaterally illustrative matter as sufficed to render the whole drama of Galileo's conflict for the Copernican theory, in its most authentic form, at once accessible to every educated German reader. The English public are now, thanks to Mrs. Sturge's labours, placed in an equally, indeed an even more, favourable position. To explain how this has come about, it is necessary to refer for a moment to circumstances which preceded the early and lamented death of the German author in September 1878.

One of the topics discussed in the greatest detail by v. Gebler in 1876 was a particular order of the Inquisition purporting to have been delivered to Galileo in 1616 by the mouth of its Commissary-General. He then held very decidedly—following the footsteps of Wohlwill in Germany, and of Gherardi in Italy—that the order in question never reached Galileo at all, and that a minute in the Vatican manuscript, purporting to report its delivery, was a forgery effected for the most sinister objects in 1633. A subsequent controversy with Prof. Berti determined v. Gebler to apply for permission to examine the original manuscript record of the trial preserved in the Vatican Archives, in order to satisfy himself by personal inspection as to the disputed point. His application, powerfully supported by the Austrian embassy at Rome, was acceded to by the Papal authorities. As the result of an investigation made in the summer of 1877, he declared himself satisfied that the disputed entry in the trial record was *not*, as he had till then maintained, a forgery, but a genuine document of the year 1616. In spite, however, of this frankly avowed change of opinion, he firmly adhered to his previously expressed convictions that Galileo had not been served with the order of the Inquisition, and that therefore the minute asserting the contrary, though genuine, stated what was inherently false. It is obvious that, had the author been called upon to prepare a second edition of his "Galileo," his changed attitude towards the forgery-question would have compelled him to effect considerable alterations in many passages of the work. This revision was, however, not destined for his hands. A predisposition to lung-disease had been fatally aggravated by ten weeks of the very heaviest literary labour, undertaken in preparing his admirably complete edition of the Vatican MS., and passed in the dangerous atmosphere of a Roman summer. He returned home greatly reduced, but had still strength to make, a few months later, a short tour among the principal cities and places historically connected with the life and memory of Galileo. On September 7, 1878, he succumbed to his incurable malady, at the early age of twenty-eight.

The reader will now be in a position to see that the preparation of an English version of v. Gebler's work presupposed a revision such as its author, had he lived to effect it, must necessarily have carried out. This task has been most judiciously performed by Mrs. Sturge, though on her title-page she modestly abstains from taking credit for it. In addition to making such alterations as the author's change of view directly entailed, she has brought the work abreast of the very latest research, and supplied in an appendix a short series of documents exactly co-extensive with the wants of the general reader as distinguished from the specialist or professed historical student. The work of translation is done with much fidelity and in a way to show that Mrs. Sturge has gone far beyond the tether of the mere translator and grasped the inner significance of the events which she had to clothe in an English dress. Her volume is not immoderately large, and its print and general appearance do credit to its enterprising publishers. While, however, this important contribution to Galileo-literature in England is thus entitled to a very hearty welcome, it contains a few minor blemishes which it may be well in conclusion just to indicate.

The translation is occasionally verbally inaccurate Thus *die Acten des Processes* is systematically rendered the "Acts" instead of the "Records" of the Trial. At p. 8 we read of Galileo's "intellectual" (instead of 'clever' or 'ingenious' = *geistreich*) "treatment of physics." On p. 46 "*in seinem betreffenden Schreiben*" is translated "in his striking letter," where the real meaning is of course "in his letter referred to." At p. 272 it is said that Galileo had better beware of the Holy Office, whereas in the original the word *Jene* shows that *other* persons were meant. "*Ex suppositione*" is translated "as a conjecture" (p. 203), where "assumption" is obviously the proper equivalent.

In the English version of a Latin document (p. 78) the original of which is given in a note on the same page, the corrupt reading "Rottz" displaces the right reading "Rose." Further, "Augustino" and "Mongardo" appear as nominative cases, and "*dioc. Politianeñ*" is rendered diocese of "Politianeti" instead of "Montepulciano."

The title of Prof. Reusch's volume might easily lead one to expect some further elucidation of the oft-mooted question to what extent the measures taken against Galileo were instigated by the Jesuits. It turns out,

[1] Reviewed in NATURE, vol. xiv. p. 226.

however, that nineteenth, not seventeenth, century Jesuits are the main objects of the writer's animadversion. Certain Fathers of that Order have recently made elaborate attempts to whitewash and even decorate the Inquisition at the expense of its illustrious victim, and it is to these that their well-known "Old Catholic" opponent now calls hostile attention. The attack on these writers, however, occupies only a comparatively small portion of the work, and will be best noticed further on. Its bulk is made up of a laboriously complete collection of historical matter bearing on Galileo's trial, and of detailed disquisitions on every question of importance flowing from that perennial source of interminable controversy. Prof. Reusch claims for his book that it should be regarded not as "merely an improved and enlarged edition of that of v. Gebler," but also as containing a detailed examination of a question which the young Austrian writer was "not theologian enough thoroughly to discuss," viz., "What do we learn from the condemnation of the Copernican doctrine in 1616, and from the sentence on Galileo in 1633, in reference to the authority claimed at Rome for the decision of theological and quasi-theological controversies?" It will thus be seen that the author's main object is practically an anti-infallibilist polemic, into the merits of which it would be improper to enter here. In the few criticisms now to be made on his work I shall limit myself strictly to its historical and literary side.

The volume before us—a closely-printed quarto of 482 pages—is assuredly entitled to be called an "enlarged" edition of v. Gebler's work, but its author's claim to have also "improved" on the labours of his predecessor seems, in one important respect, open to serious question. Von Gebler, it will be remembered, while conceding the genuineness of a particular document, stoutly maintained to the last that *its contents were essentially false*. Reusch argues that the document is genuine, and *its contents true*. His view on this crucial question is therefore opposed to that of the writer whose work he is "improving," and its substitution for the position deliberately reaffirmed by v. Gebler cannot be recognised as a process of "improvement" until the formidable series of arguments in support of that position constructed by Wohlwill and Gherardi, and very fully set out in the pages of v. Gebler himself, have been essentially invalidated. Into the details of our author's elaborate attempt to supply such an invalidation space forbids me to enter. I can only express my personal opinion that it is based on unsupported conjectures more inherently improbable than the closely concatenated inferences which he labours to overthrow. In spite, moreover, of his zealous and conscientious efforts in the collection of illustrative materials from every possible quarter, the result is marked by a diffuseness and a want of orderly arrangement which are only too likely to exhaust an ordinary reader's whole stock of patience long before he reaches the conclusions to which this formidably extensive pile is designed to lead up. Prof. Reusch's reasoning itself is somewhat ponderous, and shows but little trace of the eager perspicuity which lends such coercive force to the arguments of his chief opponent, Wohlwill.

The most telling part of his book undoubtedly is his attack on the modern Jesuit commentators already referred to, in which our author's hearty detestation of crooked literary practices comes out with refreshing vigour of expression. He points with indignation to their systematic efforts to aggravate the dark spots in Galileo's private life, the weak points of his character, and other like matters of little or no bearing on the main issue; he reprehends their attempts to minimise or explain away the harsh dealings of the Holy Office with its illustrious prisoner; he condemns their inveterate habit of backing up untenable positions by misleading citations and even downright garbling. As an instance of the astounding length to which these advocates are prepared to go in the defence of their *thesis* he quotes the statement of Grisar to the effect that Galileo's judges "could not have had the faintest suspicion" that he would be unable to give a conscientious assent to their decision. When the same writer goes on to justify this assertion on the ground of the humiliating expressions of self-abnegation used by the unhappy prisoner during his examination under the paralysing influence of fear, it is certainly, as Reusch himself remarks, "difficult, even for a Jesuit, to write anything more Jesuitical."

It is much to be regretted that in anything coming from the pen of one who has done such good service to the cause of Galileo literature as has M. Henri de l'Epinois, arguments should be found presenting even a superficial resemblance to those so justly denounced by Prof. Reusch. Certainly, however, his latest popularly written little account of Galileo's trial contains statements and inferences of a kind to make one hope that they may have been admitted into its pages on trust from other writers without passing the author's personal scrutiny. I must justify this remark by reference to particular instances.

One of the strongest pieces of evidence on the side of Wohlwill and his school is a certificate written by Cardinal Bellarmine in 1616, stating that only the declaration of the Index Congregation with regard to the Copernican doctrine had been communicated to Galileo. The whole force of the document depends on the word *only*. M. de l'Epinois, in giving an account of the hostile argument founded on this document (p. 227), summarises its contents so as to omit this pivot-word altogether.

On the following page, Bellarmine's having used words which by implication excluded the delivery of a stringent personal injunction to Galileo is toned down into his having "said nothing about" this injunction.

On p. 229 the fact of an unsuccessful search having been made in the Vatican archives for a particular missing document is described as resting only on vague report (*dit on*), whereas since the appearance of v. Gebler's edition of the trial-record in 1877, we know that the fact was officially vouched for by the Cardinal Secretary of State himself.

In endeavouring to prove (p. 250) that the Commissary of the Inquisition did actually deliver his injunction in 1616, M. de l'Epinois says that it never occurred to Galileo to deny the fact in the course of the proceedings of 1633. He lays stress on the admission of the accused that Dominican monks were present during the interview with Bellarmine, one of whom may have been the Commissary, but omits to mention Galileo's affirmation that they said nothing to him, and that he did not know who they were. He emphasises the fact that the written defence of the accused admitted the reception of an order

from the Inquisition, but passes over in silence Galileo's perfectly explicit declaration that the order in question had come to him through no other person than Cardinal Bellarmine. Any one who knows how different are the parts assigned in the Vatican manuscript to the Cardinal and to the Commissary will see at a glance the serious nature of this last omission.

On p. 231 an argument is advanced, the futility of which one would have thought must have been obvious to the possessor of the most elementary knowledge about inquisitional suits in general, and that of Galileo in particular. M. de l'Epinois expresses astonishment that Galileo, if he was really conscious of having been condemned on a trumped-up charge, should not have left behind him, in letters to his friends, some protest against the abominable act of fraud of which he had been the victim.

Now, in the first place, it was the regular practice of the Inquisition to exact from those who appeared at its bar an oath of absolute silence, under pain of excommunication in case of contravention, as to everything which had occurred within the sacred tribunal. We know from the Vatican MS. that this precaution was taken in the case of Galileo. Further, the sentence of 1633 menaced him with being treated as a relapsed heretic (*i.e.* burned alive) if he should venture to treat of his condemned opinion of the earth's motion in any manner whatever. Lest it should be supposed that this was a piece of mere formality, the Inquisitor of Florence, during Galileo's subsequent practical imprisonment in his own villa at Arcetri, threatened him in the most unmistakable language with immediate incarceration in the actual dungeons of the Roman Inquisition if he should dare to propagate in conversation the Copernican doctrine.

It requires, then, little prophetic gift to foresee what would have befallen Galileo had he been detected setting in circulation a charge of the blackest fraud against the supreme tribunal of the Inquisition. His silence on the subject can cause those who believe in the reality of this fraud no astonishment whatever. The only surprise they are likely to experience is that a writer so exceptionally acquainted with the details of Galileo's case as is M. de l'Epinois, should have esteemed an argument of this kind worthy of a place in his pages.

I cannot think that M. de l'Epinois is more successful in setting up a positive theory of his own than he is in demolishing that of Wohlwill. He maintains a thesis favourable to the Roman authorities, but it is based on efforts to explain away, or assert away, palpable contradictions, and on gratuitous and mutually destructive assumptions. In short, his whole treatment of the issue essentially in dispute is both superficial and unsatisfactory.

Father Desjardins, of the Society of Jesus, tells the world that, inspired with sacred boldness (*de saintes audaces*), he has torn from the hands of the Church's enemies a weapon of which they had made sinister use, by restoring to the incident of Galileo so long travestied by ignorance and bad faith, its veritable physiognomy. His preface concludes with the following piece of advice to such of his readers as may be disposed to criticise the acts and institutions of the Roman Church in this or any other case:—

"Approve everything without hesitation, and soon philosophic examination will reward your confidence by presenting to you a complete demonstration of all these things!"

Such a maxim is so little likely to find favour with readers of NATURE that I shall trouble them no further with the magniloquent Jesuit's production which is as superficial, arrogant, and inconclusive as its pompous exordium would lead one to expect.

In terminating this notice it may be as well to remark that the question whether Galileo was or was not fraudulently convicted and condemned remains still undecided. The Roman authorities have not as yet taken the one step which offers some chance of settling, and could hardly fail essentially to narrow, the issue. This consists in allowing free access to, and facsimile reproduction from, all and every portion of the Vatican MS., instead of restricting, as appears hitherto to have been done, this privilege to members of the Roman Church supported by ambassadorial or episcopal recommendations.[1]

SEDLEY TAYLOR

THE MANUFACTURE OF SULPHURIC ACID AND ALKALI

A Theoretical and Practical Treatise on the Manufacture of Sulphuric Acid and Alkali with the Collateral Branch. By George Lunge, Ph.D., F.C.S., Professor of Technical Chemistry at the Federal Polytechnic School, Zurich (formerly Manager of the Tyne Alkali Works, South Shields). Vol. i. (John van Voorst, 1879.)

WE heartily welcome Prof. Lunge's volume on the manufacture of sulphuric acid. It is the result of a rare combination of thorough knowledge of scientific theory with that intimate experience of the practical manufacture which can only be gained by those who come into daily contact with the problems presenting themselves in dealing with chemical operations on a large scale.

In his preface our author distinctly states the object he has in view, and very modestly but clearly indicates the claims upon which he founds his right to speak: "The present treatise," he says, "is intended to supply various wants, and accordingly appeals to various classes of readers. In the first place, it gives a scientific description of all the substances occurring in the manufacture of sulphuric acid, alkali, and bleaching powder, either as raw materials or finished products, according to the most recent statements. Secondly, it is intended as an aid in the study of technical chemistry by giving a complete description, both technical and theoretical, of all the processes occurring in this series of manufactures. Its third and principal object is to give to practical manufacturers both complete and reliable information upon all the apparatus and processes which have come under the author's notice. . . . Much space is taken up by the discussion of the innumerable publications in English, German, and French, referring to this industry, but even more space was required for the faithful rendering of the author's personal observations and experiences. His own practice of eleven years in the north of England has been

[1] Wolynski. Nuovi documenti inediti del Processo di Galileo Galilei Firenze, 1878, p. 13.

supplemented by numerous visits to other alkali-manufacturing districts of Britain and the Continent. The author's present position as professor at a technical high school enables him to state frankly what he knows and what he has seen, since he can expect no benefit from keeping anything back."

Every one who reads the volume before us will feel that Prof. Lunge has admirably succeeded in the serious task which he has set himself to accomplish, and there is no doubt that he has thus not only filled up an important lacuna in our chemical literature—for in no sense can any other existing work on the subject be said to be satisfactory—but he has given us a work which must become a standard one.

The importance and magnitude of the British sulphuric acid trade will best be understood when we remember that cheap glass and cheap soap—or light and cleanliness—depend upon the cheap production of oil of vitriol; and when we learn that Great Britain manufactures about five-eighths of the production of the world, and that the annual amount made in this kingdom now reaches the enormous figure of 832,000 tons.

Nor is it in quantity alone—although that is, after all, the true measure of a successful trade—that the English manufacturers stand pre-eminent. In all the great improvements which have taken place, England has fully held her own with her perhaps more highly-educated Continental rivals. Thus, although the introduction of pyrites in place of brimstone is often accorded to Messrs. Perret of Chessy, in 1835, there is no doubt that Mr. Hill of Deptford patented the process in 1818, whilst the first to employ pyrites on a large scale was Thomas Farmer of London. Passing again to the mechanical devices for burning pyrites, we find that Dr. Lunge gives an unfavourable opinion as to the construction and mode of working of the Continental burners, and acknowledges that the English form is that which yields the best results, and is now being largely introduced in both France and Germany.

Then, again, as regards the construction of the now all-important leaden chamber, we find that an Englishman, Dr. Roebuck of Birmingham, was the first to erect such a chamber in 1746. And if it is to the genius of Gay-Lussac in 1827 that we owe the idea of the recovery of the excess of escaping nitrous fumes, by passing the exit gases through a shower of strong sulphuric acid, we must remember that this part of the manufacture was not perfect until Mr. Glover proposed the addition of his denitrating tower. All these, and many other inventions and appliances made by intelligent English manufacturers, are clearly stated by Dr. Lunge, who appears to be perfectly free from bias, and discusses the whole subject with a thoroughly scientific spirit. Our English system of Government inspection of sulphuric acid works also comes in for a proper share of notice and commendation, although we do not find mention made of the labours of the recent Noxious Vapours Commission, founded upon whose report the Government have brought forward a new Noxious Vapours Act, which is to include a large number of works, especially vitriol works, which as yet are not placed under inspection. Several of the various proposals which have been made by the chief inspector, Dr. Angus Smith, and his staff, are dwelt upon. Especially we would notice Fletcher's valuable anemometer for the measurement of the draught in flues and chimneys, upon the results of which the escapes of acid are ascertained.

Dr. Lunge has lived so long amongst us that he not only fully appreciates highly our manufacturing skill, but he is able to express his appreciation in terse and luminous English. The illustrations, too, with which the volume teems are of the highest excellence, drawn, as they all appear to be, to scale, and engraved with the care and precision which is characteristic of the great publishing house of Vieweg and Sons of Brunswick. From whatever point of view we consider his labours, there is no doubt that they will be highly valued both by students and manufacturers, and we can confidently recommend this first volume of Dr. Lunge's work to all those who, from the scientific or from the practical side, are interested in this most important chemical manufacture.

H. E. ROSCOE

OUR BOOK SHELF

On the Origin of the Laws of Nature. By Sir Edmund Beckett, Bart. (London: Society for Promoting Christian Knowledge, 1879.)

THIS is a very clever little book, and deserves to be widely read. Its subject, however, is scarcely one for our columns. For it is essentially "apologetic," and its strong point is not so much accurate science as keen and searching logic. It dissects with merciless rigour some of the more sweeping assertions of the modern materialistic schools, reducing them (when that is possible) to plain English so as to make patent their shallow assumptions. When, from the inherent vagueness of a statement, the author finds himself unable to present it in intelligible and simple language, he gives by apt analogy a clear view of its absurdity. He follows out in fact, in his own way, the hint given by a great mathematician (Kirkman) who made the following exquisite translation of a well-known definition:—

"Evolution is a change from an indefinite, incoherent, homogeneity to a definite, coherent, heterogeneity, through continuous differentiations and integrations."

[*Translation into plain English.*] "Evolution is a change from a nohowish, untalkaboutable, all-alikeness, to a somehowish and in-general-talkaboutable not-all-alikeness, by continuous somethingelsifications and sticktogetherations."

The following quotations, taken almost at random, give a fair idea of the style of the book:—

"You may say perhaps that this is just Hume's famous argument against miracles, viz. that all experience is against them, while lying is not at all contrary to experience. But that again is a mere paradox, or a verbal trick which either begs the question or is absurd. For if by 'all experience' he meant literally all experience, that simply begs the question; and if he meant only general experience, it sinks into the platitude that miracles are uncommon. Again, if the prevalence of lying were a sufficient reason for disbelieving any extraordinary story, then we must not believe that any extraordinary event ever happened: which is absurd."

"In that respect there is no difference between a single atom and that congeries of atoms which for the time makes up a man: at any rate atheistical philosophers admit none: according to them it is matter (*i.e.* the atoms of it) 'that has the promise and potency of life,' and man is only a machine resulting from their spontaneous action under laws and forces which always existed without any cause. But if the most determined man in

the world resolves ever so firmly to walk to a place a mile off, that initial resolution will never get him there unless he further resolves at every moment of his walk to take the next step, and takes it."

" . . . . Atheistic philosophers are always insisting on the fact that whatever powers have made the world, have made it and kept it going and improving by means of invariable laws or modes of action. Then if uniformity of action *of the proper kind* can do the business so well, why should it be varied? This argument against a creative will in other words asserts that there can be no such will because the plan and rules by which it uniformly acts are so good that they have never to be varied in order to repair a single defect or produce a single improvement; *i.e.* 'there is no creator and maintainer of the world because the design was so perfect. If we had seen the universal machine working by fits and starts we should certainly have admitted that every one of them involved a fresh application of power; but we deny any because it works so smoothly that it seems to go of itself, though it is always turning out products of infinite variety, and in some respects continually improving.' Such an argument as that only needs stating nakedly to answer itself. . . . . A machine that will go on for ever producing ever-varying and ever-improving results is manifestly and infinitely superior to one that needs continual interference, and implies infinitely greater wisdom in the maker of it."

" . . . . the leaders of the materialistic school give us such dogmatic statements as that 'materialism is the best working hypothesis,' and that 'it is a fundamental law of psychology that all beliefs as to the past and the present must rest on experience.' But they neither pretend to prove that 'fundamental law,' nor to tell us who made it, except themselves, nor why a hypothesis is the best working one which explains nothing, but merely asserts, when turned into plain English, that things are because they are; and that mind is only the result of certain motions of matter, without professing to explain how a single particle of matter came to be able to move itself . . . . all this language of the materialists or atheists, or sceptics, or whatever else they call themselves, is not demonstration but mere assertion, which could just as well be made the other way."

When the purposely vague statements of the materialists and agnostics are thus stripped of the tinsel of high-flown and unintelligible language, the eyes of the thoughtless who have accepted them on authority (!) are at last opened, and they are ready to exclaim with Titania

Methinks "I was enamour'd of an ass."

As the touch of Ithuriel's spear at once happily revealed the Deceiver, these frank and clear exposures of the pretensions of pseudo-science cannot fail of producing great ultimate good. P. G. TAIT

The Home of the Eddas. By Charles G. Warnford Lock. With a Chapter on the Sprengisandr by Dr. C. Le Neve Foster. (London: Sampson Low, Marston, and Co., 1879.)

ANOTHER volume of Icelandic travel has been added to the lengthy series which already loads the book-shelves of those who are interested in that wonderful country of frost, and flood, and fire. More than fifty such works have been published during this century; some discussing the geology, others the natural history of the country; others the characteristics of the people, and of their literature; many are simply records of travel, some are mere clumsily-constructed diaries. We fear we must class the volume before us among the latter. It is a mere diary, and in good sooth the most intolerably dull diary we ever read. We have searched in vain for any new facts, any new views concerning old facts, any local and individual colouring. The author has travelled over old ground, by the old methods, permeated by the ideas of his predecessors. Let us, however, give him his due. He is a brave man, and a contented man. Never were dangers more pluckily faced; never did a man grumble less under the most trying circumstances. Many men with less perseverance, less hardihood, less indomitable spirit, have made considerable discoveries, achieved great results. He travels twelve or twenty hours at a stretch in mid-winter; he fords foaming torrents; traverses treacherous bogs; crawls all-fours over ice-slopes; puts up with the most miserable accommodation and food, and yet is always cheerful, and always makes the best of things. Often he gets soaked to the skin in a glacier river, and has to sleep in his wet clothes in a pestilential baðstofa. Often after a weary day's march he has to go supperless to bed. That all his labour should have resulted in so little—we fear we must say, in no—gain to art, literature, or science, is quite deplorable. But the fact is, records of Icelandic travel are worn threadbare. More than fifty years ago the works of Mackenzie and Henderson appeared; less than four years ago the two-volumed "Ultima Thule" of Capt. Burton gave us the most recent experiences of an accomplished traveller. For a general description of the country we still prefer Henderson; Baring-Gould's "Scenes and Sagas" furnishes a pleasant, chatty volume of travel, full of north-world lore; while Prof. Bryce's "Impressions of Iceland," in the *Cornhill Magazine* for May, 1874, is the very type of a well-written general article on the subject; full of condensed observation, wide in limit, admirable in style, masterly in treatment. One thing could have partially redeemed "The Home of the Eddas" from its dull monotony: had it been well illustrated with views not commonly met with in Icelandic works of travel, it would have been a redeeming point. But, alas, there is not a single illustration.

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts. No notice is taken of anonymous communications.*

[*The Editor urgently requests correspondents to keep their letters as short as possible. The pressure on his space is so great that it is impossible otherwise to ensure the appearance even of communications containing interesting and novel facts.*]

Swift's Comet

THE following position of the comet was obtained from three comparisons with the star *Dm* + 84°, No. 60. From a single comparison of the star with *Carrington* 447, the declination of the *Dm* appears to require the correction − 8″, but I have not applied it to the comet's place. The declination of the ephemeris of the comet, in NATURE, vol. xx. p. 248, requires a correction of only + 0′·6.

Hissarlik

I SEE in NATURE, vol. xx. p. 255, a statement, which has also appeared in the *Times*, that Prof. Virchow has written to my friend, Dr. Schliemann, stating that there is a concurrence of geological opinion in Berlin that all the building stones, fragments of which the professor brought home from Hissarlik, are of fresh-water formation. This conclusion it is said is thought to be decisive against those who affirm the impossibility of identifying Hissarlik with the Homeric Troy on the ground that at the time of the great epic, the site must have been covered by the sea. I am, however, unaware that it has ever been argued that the actual site of Hissarlik was covered by the sea, but only that Hissarlik was probably on the sea-shore, a position which would be quite inconsistent with the statements of Homer. I have never committed myself to this opinion, but I

may be allowed to point out that the fact mentioned by Prof. Virchow favours rather than disproves this view. If the plain between Hissarlik and the sea has been gradually formed by the detritus brought down by Scamander the materials would be of fresh-water origin. The observations made by Dr. Virchow appear therefore to me by no means to bear out the conclusions which it is said have been drawn from them.

15, Lombard Street, E.C., July 12 JOHN LUBBOCK

On the Origin of Certain Granitoid Rocks

DR. HICKS has very properly called attention to his prior discovery of the transitional nature of some hälleflintas, and I regret that I overlooked this point in his valuable papers on the Pembrokeshire rocks. I may, however, be permitted to point out that my observations in Shropshire go further than those of Dr. Hicks, since the hälleflinta observed in the Wrekin range passes not merely into "incipient gneiss, the metamorphic action being incomplete, a kind of semi-metamorphism and softening having taken place, etc."; but into a true gneiss, distinctly foliated in bands of quartz, felspar, mica, and sometimes hornblende, and into granitoidite and granite. In the Wrekin we see the completion of the change of which Dr. Hicks recorded the earlier stages. C. CALLAWAY

Wellington, Salop, July 12

The Telephone

EXPERIMENTS that I have recently made with a "Bell" telephone have convinced me that the sounds produced are the result of molecular change in the iron disk, and are the same in kind as those heard in the telephone of Reiss.

My experiments were made with a carbon transmitter and Bell receiver, using a small battery to generate the current. First I removed the bar magnet from the receiver, in accordance with a suggestion made by a writer in NATURE some months ago. The effect without the magnet was the same as with it. It then occurred to me that the intensity of the sound might be increased by using two disks instead of one. Accordingly I cut two circles out of a piece of sheet iron, leaving a narrow strip of the metal to connect them, of sufficient length to enable the disks to lie on either side of the reel, so as to form, in fact, an armature to the electro-magnet. On experimenting with this my anticipations were fully realised, the sound produced being more than double that from a single disk.

Now, while trying these experiments I held the disks loosely in my hand, without their being in any way fastened to the wood holding the reel, the effect being the same as if firmly secured. In fact, a common dinner knife or a rough piece of iron would emit sound if brought near enough to the core of the electro-magnet.

I have since constructed a very efficient telephone receiver out of a block of wood two inches square and three-quarters of an inch thick. I then drilled a hole sufficiently large to receive the reel, and covered the block with thin sheet iron. It needs no ear-piece, and forms the most effective telephone receiver that I have seen. But, still further to prove that the sounds produced are due to the magnetisation of the iron of the disk, and not to mechanical vibrations resulting from the electro-magnet, I made an iron reel, the flanges of which were two inches in diameter. Now, on covering this reel and placing it in circuit, the flanges of the reel gave out sound as clearly as in the Bell telephone. In my judgment this experiment renders it conclusive that the sounds proceed from the magnetisation and demagnetisation of the iron, and are therefore precisely the same in character as those formed by a Reiss receiver.

Inherited Memory in Birds

SOME interesting communications have lately appeared in NATURE on this subject, accounting for the wonderful knowledge of routes and localities displayed by birds in their migrations, by the theory that the impressions made on the brains of the parents are transmitted to their offspring, and that which we call vaguely instinct is often inherited memory.

The following circumstance is hard to explain on any other theory:—

About twelve years ago I was residing on the coast of Co. Antrim, at the time the telegraph wires were set up along that charming road which skirts the sea for twenty-five miles between Larne and Cushendall. During the winter months large flocks of starlings always migrated over from Scotland, arriving in the early morning. The first winter after the wires were stretched along the coast I frequently found numbers of starlings lying dead or wounded on the roadside, they having evidently in their flight in the dusky morn struck against the telegraph wires, not blown against them, as these accidents often occurred when there was but little wind. I found that the peasantry had come to the conclusion that these unusual deaths were due to the flash of the telegraph messages, killing any starlings that happened to be perched on the wires when working.

Strange to say, that throughout the following and succeeding winters hardly a death occurred among the starlings on their arrival. It would thus appear that the birds were deeply impressed and understood the cause of the fatal accidents among their fellow-travellers that previous year, and hence carefully avoided the telegraph wires; not only so, but the young birds must also have acquired this knowledge and perpetuated it, a knowledge which they could not have acquired by experience or even instinct, unless the instinct was really inherited memory derived from the parents whose brains were first impressed by it.

Sudbury, Suffolk J. SINCLAIR HOLDEN

Butterfly Swarms

SOME, at least, of the swarms of *V. cardui* originate in Africa, one of which I witnessed a day's march west of Sowakin, in Nubia, in March, 1869. Our caravan had started for the coast, leaving the mountains shrouded in heavy clouds, soon after daybreak. At the foot of the high country is a stretch of wiry grass, beyond which lies the rainless desert as far as the sea. From my camel I noticed that the whole mass of the grass seemed violently agitated, although there was no wind. On dismounting I found that the motion was caused by the contortions of pupæ of *V. cardui*, which were so numerous that almost every blade of grass seemed to bear one. The effect of these wrigglings was most peculiar, as if each grass stem was shaken separately—as indeed was the case—instead of bending regularly before a breeze. I called the attention of the late J. K. Lord to the phenomenon, and we awaited the result. Presently the pupæ began to burst, and the red fluid that escaped sprinkled the ground like a rain of blood. Myriads of butterflies limp and helpless crawled about. Presently the sun shone forth, and the insects began to dry their wings; and about half-an-hour after the birth of the first, the whole swarm rose as a dense cloud and flew away eastwards towards the sea. I do not know how long the swarm was, but it was certainly more than a mile, and its breadth exceeded a quarter of a mile.
